Third Day —At 2 A.M the blood pressure fell suddenly to 85 mm Hg Intravenous eucortone 10 ml and intramuscular eucortone 10 ml. with intramuscular deoxycortone acetate 10 mg were given and an intravenous saline infusion was started. Intravenous eucortone 10 ml hourly was continued At 8.30 A M the blood pressure was 50/30 mm. Hg Intravenous eucortone 20 ml was given and a plasma drip was substituted for the saline infusion. Intravenous eucortone 10 ml. half hourly was continued until 2.30 P.M after which intramuscular eucortone 10 ml was given hourly with three additional intravenous doses of 10 ml. each At 10 A.M the blood pressure was 70 mm. Hg Cortisone therapy 25 mg. six hourly by mouth was started During the afternoon the intravenous infusion was stopped for fear of overloading the circulation

TABLE II—FLUID BALANCE, BLOOD UREA LEVELS, BLOOD PRESSURE, AND DOSAGES OF EUCORTONE AND CORTISONE IN FIRST SIX DAYS OF TREATMENT OF CASE 2

Days	2	3	4	5	6	7
Intake						
Borst diet (oz)	—	—	8	30	30	12
Milk (oz)	—	29	6	—	—	87
Water (oz)	2	70	—	—	—	—
Plasma (oz)	—	20	—	—	—	—
5 % Glucose saline solution (oz)	—	40	—	—	—	—
Saline solution (oz)	—	20	40	—	—	—
Total	2	179	54	30	30	99
Output						
Urine (oz)	4	13	Nil	8	28	54
Blood urea (mg per 100 ml)	—	86	160	162	—	147
Systolic blood-pressure (mm Hg)						
Highest	130	100	70	80	100	100
Lowest	—	40	40	60	60	60
Eucortone (*ml*)						
Intravenous	—	220	160	—	—	—
Intramuscular	—	80	80	150	60	60
Cortisone (mg) by mouth	—	100	150	100	37 5	50
Deoxycortone acetate (mg)	—	10	—	—	—	—

because no urine had been passed since the morning A catheter was passed, and only 1 oz of urine was obtained. Sulphadimidine was substituted for the sulphadiazine, and the patient was put into an oxygen tent

Fourth Day—Anuria was still present Intramuscular penicillin was substituted for the sulphadimidine, and Borst diet for anuria was started The blood pressure rose in the evening to 70 mm Hg Intravenous eucortone 10 ml hourly for sixteen hours was given, and the dosage of cortisone was increased to 12 5 mg four hourly

Fifth Day—The blood pressure rose gradually, and 8 oz of urine was passed The dosage of eucortone was changed to 10 ml four hourly intramuscularly until the ninth day, when the injections were given six-hourly until they were stopped on the eleventh day The dose of cortisone was gradually reduced from the fifth day and stopped on the twelfth day Deoxycortone acetate 10 mg was given on the eighth day and 5 mg on the tenth day

Further Progress—The plasma chloride, serum sodium, and blood sugar levels remained normal throughout the illness The serum potassium level fell to 14 mg per 100 ml (3 6 m.eq per litre) on the fifth day and to 13 mg per 100 ml (3 3 m eq per litre) on the seventh day This was corrected by adding potassium citrate and milk to the diet Progress was satisfactory after the eighth day except for a proteus infection of the urine, for which aureomycin was given The C S.F contained polymorphs, and the protein therein was increased and sugar reduced for twenty days in all The patient was discharged fit after forty five days, and his blood pressure was 120/65 mm Hg after thirty days

Fluid balance, blood-urea levels, blood-pressure, and intake of eucortone and cortisone in the first six days of treatment of case 2 are shown in table II

Discussion

Gross hæmorrhage starting in the adrenal medulla and spreading out into and disrupting the cortex has often been described in meningococcal septicæmia complicated by adrenal cortical failure. Morison (1943) suggested that this change was not the cause of the adrenal failure but was secondary to peripheral vascular failure initiated by the septicæmia Schwarz (1946) attributed the clinical state primarily to destruction of the medulla, but necropsy material examined by Banks and McCartney (1943) from one of their patients who died of meningococcal encephalitis showed extensive adrenal medullary hæmorrhage though the clinical picture of adrenal failure had not been present

The work of Rich (1944) in this respect deserves consideration He described a striking transformation of the solid cords of the zona glomerulosa into tubular structures containing fibrinous exudate, these changes in some circumstances were only associated with a few petechial hæmorrhages He considered this to be an initial pathological change which, sometimes in adults and usually in children, is obscured later by massive hæmorrhage Some of the appearances described by [illegible] McCartney (1943) seem to be similar

Although in the two present cases we lack histolog proof, we think that, if changes similar to those describ by Rich did take place, they were reversed by the ear use of antibiotics, coupled with massive replacement therapy

These two cases corresponded to the pure adrenal typ described by Banks and McCartney (1943) who emphasised the value of eucortone in treatment, considering th its use might be life saving, whereas in the encephali type the outcome was always fatal

We feel that certain clinical features are worth emphasising The combination of severe and prolonged hypotension with warm flushed cyanotic extremities and comparative mental and physical well being which evident in both of the present cases, except for a cri hour in case 1, contrasts with the cold pallor of extremities seen in hypotensive states due to conditions, and in our opinion is a most import diagnostic feature

The management is best discussed under two headings general and specific In the general management emphasise the importance of oxygen therapy in controlling anoxia, in particular the restlessness cerebral anoxia, and in this respect the oxygen seems to be superior to other methods, and was life saving in case 1 Control of the fluid balance is vital importance, and care is necessary to prevent overloading of the circulation The temptation to intravenous therapy in the presence of prolonged hypotension is strong but should be resisted unless dehy or electrolyte imbalance is present It is p undesirable when a substance which promotes the re tion of sodium—e g , cortisone—is used and when may be present This anuria seems to be unpred because, though both patients had severe hypotension, one secreted urine and the other did Some slight overloading of the circulation developed both cases For this reason we feel that long- substances—e g , deoxycortone acetate—should not used in this type of adrenal cortical failure

As regards biochemical disturbance, the serum and plasma chloride levels remained normal in both in contrast with the grave disturbance seen in crises Hypoglycæmia, mentioned by Nelson Goldstein (1951) and Banks and McCartney (1943), not develop, presumably because of the administration of cortisone and eucortone The urea level rose to 105 mg per 100 ml on the third in case 1, and to 165 mg per 100 ml on the fifth case 2, who developed anuria The serum pota level fell to 12 1 and 13 0 mg per 100 ml on the and fourth days respectively in case 1, and to 14 1 13 0 mg per 100 ml on the fifth and seventh respectively in case 2 This can also be attributed part to hormonal therapy, and was corrected by g potassium salts and milk by mouth

In considering the use of specific treatment eucortone and cortisone in these two cases we work the assumption that cortisone was slower than euco in action We therefore gave eucortone in very doses in the early stages, believing that such am were necessary to overcome the sudden rapid lo cortical function, and that in the past it had been in inadequate dosage

Since we did not know whether absorption from stomach in a desperately ill patient would be cortisone was given at first intramuscularly It has shown that an oral dose of 200 mg produces a blood level in an hour, and a maximal eo response, demonstrable for eight hours, after four (Nelson et al 1952) An intramuscular injecti effective in 6–8 hours

We therefore suggest that, in addition to the treatment of the infection, cortisone should be month in an initial dose of 100 mg followed by mg six hourly until the infection is controlled and patient is out of danger the dose being reduced to 5 mg six hourly for the following two days, and the al daily dose being thereafter halved every second y A large initial dose—e g 50 ml —of intravenous cortone should be given and followed by one of 20 ml hour later and further doses of 10 ml. hourly until systolic blood pressure is maintained at 80 mm Hg ese doses are large but the demands on the adrenal rtex are known to be great in the presence of severe ection.

Summary

Two cases of *meningococcal septicæmia and adrenal rtical failure, treated by eucortone and cortisone* are ported.

Both patients survived

During the critical stage of the illness, frequent large ses of eucortone intravenously and of cortisone by outh six hourly are advised in combination with tibiotics and oxygen therapy in a tent.

We wish to thank Dr A. M. Cooke for permission to publish e second case; Mr J R. P O Brien and Dr Paul Fourman r much valuable assistance and criticism; and the sister d nurses of Rowney ward for their unceasing care of the o patients.

THE sickle-cell trait has been known for many years to ccur sporadically in persons from Greece Choremis ervos, Constantinides, and Zannos (1951) first discovered local concentration of the trait in that country in nd around Petromagoula. Caminopetros (1952), using r very long periods the Scriver and Waugh (1930) tech ique of prolonged sealing up of blood without added agent, then claimed to have found a very high incidence mong Greeks in general, approaching 50% in Athenians. aminopetros s results could not be obtained regularly n the same blood.

The observations of one of us (Choremis 1952) had own that such frequencies certainly did not exist nd in our opinion (Lehmann 1953) the technique adopted was, in addition to showing genuine sickle cells almost certainly distorting normal red cells so that they some what resembled sickle cells In our view Caminopetros did not appreciate the fact that, as his results were obtained irregularly and could not be repeated every time on the same blood, only the chemical method could decide whether his claims were correct. In the Scriver Waugh technique bloods are tested by sealing up the specimen on a coverslip and incubating it. Under these conditions the leucocytes use up the oxygen in the confined space and eventually reduce the hæmoglobin. On prolonged incubation however changes may take place in the composition of the plasma which can exert external stresses on the red cells and alter the shape of normal red cells until they become remarkably like sickle cells (Isaacs 1950) The two types of sickle cells caused by external and by internal causes will be called in this paper "false" and "true" sickle cells respectively It was clearly desirable that a fresh survey should be made, using the much more rapid and reliable method of reducing hæmoglobin in the red cells by added reducing agents.

True and False Sickling

Pauling et al (1949) have shown that the sickle-cell trait, found characteristically in Negroes, depends on the presence in the red cell of a variable amount of an abnormal hæmoglobin with well defined physico-chemical properties which differentiate it clearly from normal hæmoglobin Reduced sickle-cell hæmoglobin has a very low solubility in water and in the red-cell fluid (Perutz et al 1951) Thus, on reduction the abnormal hæmoglobin will crystallise inside the red cells and the crystals will distort the cell envelope and give the cells the bizarre shape described as 'sickle cell' Some of the true sickle cells have two points only but there are always some and sometimes many with more than two points and with one or more sharp re-entrant angles. External stresses can, however distort the envelope of red cells containing only normal hæmoglobin to give them a shape resembling that of sickle cells. Under these conditions the cells are usually fusiform rather than sickle shaped they tend to retain something of a central bulge with drawn-out processes at each side. They seldom have more than two such points and if any re-entrants or embayments are present, they are rounded and not angular True sickle cells are arranged irregularly, but in 'sickling' due to external stresses the cells tend to arrange themselves in patterns there are chains with the point of one cell adjacent to that of the next or they may form rosettes The easiest way of demonstrating false sickling is by adding to a drop of fresh blood on a slide a few mg each of fibrinogen and of thrombin stirring with a match-stick, and then pressing down a cover glass.

The Scriver Waugh technique will show up true sickling if present, after not more than twenty four hours, provided that the leucocytes retain a certain amount of metabolic activity If the preparations are kept longer than this, changes in the composition of the serum are liable to cause false sickling Repeated tests on the same specimen may then yield varying results In our opinion this is what happened in the preparations of Caminopetros Agglutination, especially with anti Lewis sera may also give rise to an appearance resembling false sickling

Figs 1 and 2 show the difference between the two types of sickling Fig 1 taken from Huck (1923) shows the above-described features of true sickling whereas fig 2 from Dreyfuss et al. (1951) shows those of false sickling It was only through the generous attitude of Dr. Dreyfuss that we were able by repeating tests on Yemenite Jews previously tested by him both by incubation and by chemical tests to work out fully and to our own satisfaction the differences between

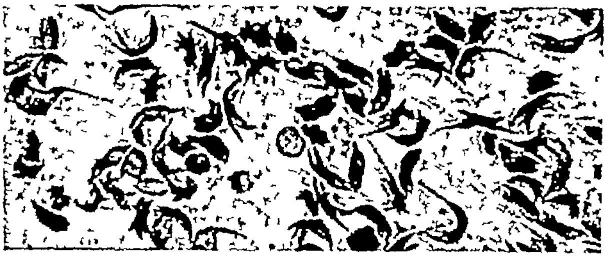

Fig 1—True sickling (Huck 1923)

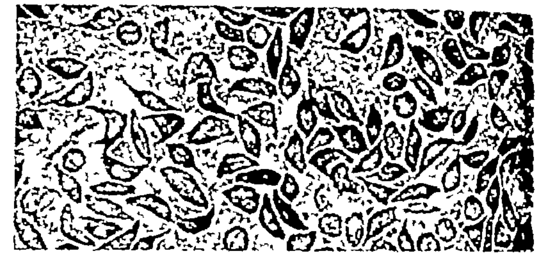

Fig 2—False sickling (Dreyfuss et al 1951)

these two types of "sickling" (Dreyfuss, Ikin, Lehmann, and Mourant 1952) Though it is desirable that all cases of sickling should be confirmed by the chemical reduction method, simple anaerobic incubation is almost equally reliable, provided that it is not continued for more than twenty four hours, and that the observer is familiar with the morphological distinctions between true and false sickling Thus the abnormally shaped cells from deer blood, figured by Gulliver in 1840 and reproduced by Singer (1951), are probably not true sickle cells as suggested

One of us (H L), in scrutinising past reports on sickling in the light of these new experiences, has become suspicious of his own findings in two African tribes which were part of a large number of observations made in Uganda in 1948–49 (Lehmann and Raper 1949) In the Kakwa tribe an original sickle-cell trait incidence of 12% was found to be increased to 25% by leaving the preparations overnight, but the increase was entirely due to the appearance of what are now recognised as false sickle cells In the Bakonjo tribe samples from some individuals (taken by finger pricks) were examined after they had been working in a salt lake, and all the members of this group, otherwise unselected, showed the false type of sickling This increased the reported incidence for the tribe as a whole

Incidence of Sickling in Greece

In view of the divergent views expressed on the incidence of sickling in Greece as a whole, and of the possibilities of error which have been shown to exist, especially by the controlled tests on Yemenite Jews, it was clearly desirable that Greeks from all over the country should be tested for sickling by chemical means We therefore examined the blood of 110 Greeks, 50 born in Athens and 60 in other parts of Greece, but not from Petromagoula These people were unrelated to one another, and, apart from being available in Athens, they could be regarded as unselected

Samples were sent to London by air in three batches They consisted of capillary blood enclosed in sealed glass tubes, and each batch was accompanied by one or two samples taken from known Greek sicklers who [illegible], not included in the series All the samples [illegible] by incubation with sodium metabisulphite (Daland and Castle 1948) and with sodium hydrosulphite (Williams and Mackey 1949) The known sickle- bloods all yielded positive results, whereas the 11 unselected samples were uniformly negative

Blood-groups in Greece

In view of the paucity of data on Greek blood group in general, and of the implications, discussed below of both sickling and Rh groups on possible A connections, it was decided to determine the ABO Rh, and MNS blood groups of all the specimens A sickling tests had been carried out at St Bartholomew's Hospital, the specimens were transferred for grouping to the Blood Group Reference Laboratory

Samples were tested with anti-A, anti B, anti-C anti c, anti D, anti E, anti M, anti-N, anti-S, and anti Henshaw Samples positive with anti A were further tested with anti A_1, positives with anti E were tested with anti e, specimens negative with anti D in saline solution were submitted to an indirect antiglobulin *test with "incomplete" anti D in order to detect* D^u antigen if present

The results of the tests are set out in tables I–III. Gene frequency calculations were made by Dr Ada C K by the methods briefly described by Allison et al (19 which will be more fully described by Mourant (1953)

Discussion

Considerations of independent mutation apart, the absence of any example of sickle cell trait among 110 unselected Greeks makes a large Negroid or Ved doid component in the general population unlikely Even the presence of sickling locally at Petroma (Choremis et al 1951) does not necessarily imply an African connection, since a high frequency of this trait has now been found in Veddoids in India (Lehmann and Cutbush 1952a and b) and Arabia (Lehmann and Ikin 1953) On the other hand, the frequency of the cDe (R_o) chromosome is 4 6%, which is higher, though not significantly so, than in northern and central Europe and nearer to the frequencies found in several other Mediterranean lands, where it is almost certainly due to a small African component in the population It thus remains possible that the sporadic cases of sickling in the Mediterranean area have a similar origin, though they may have come from Asia (Lehmann 1953)

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—Dr Mac Keith, in his article last week on the anagement of children in hospital before operation als with a subject of great importance to plastic rgeons and others concerned with the treatment of ngenital deformities needing repeated operations The ue facts about the efficacy of current pre anæsthetic gents for children are less reassuring than he implies

If the objective is a child quiet and amnesic for the hole of the induction period then it is my view that is objective is still not attained in most hospitals here is more involved than the choice of pre anæsthetic gent. Both oral sodium pentobarbitone ('Nembutal') d rectal thiopentone are often successful. But the more ten the child is subjected to anæsthesia, the less liable these agents are Their success is largely deter ined by the skill of the ward sister in their adminis ation and in the general arrangements in the children's ard for preparing children for operation

It remains my experience over a number of years, at I hear signs of struggle and crying from the anæs etic room in a big proportion of the children on whom do operations. There are some hospitals where this is ot so In these the ward arrangements are particularly od There are others where it happens more often an not.

There is not the least doubt that the premedication of ildren is one of the most important unsolved problems modern anæsthesia—if by a solved problem we mean ne whose solution is successfully applied in most ospitals most of the time

I can amply confirm Dr Mac Keith's account of the arm which can be done in the pre anæsthetic period to hildren, and I have often had to modify an important rogramme of repair because of the severe emotional ffects which the stress of the pre-anæsthetic battle has n the child. For any child to go conscious to the næsthetic room smacks of the surgical Middle Ages.

London, W 1 PATRICK CLARKSON

SIR,—Dr Mac Keith's excellent paper lacks a summary his might well be: Treat children as adults and they re easy *treat them as children and everyone suffers*

Children are not naturally afraid of anything even ospitalisation and anæsthesia unless a fear has been reviously instilled in them One way to ensure the onfidence of the child is for the anæsthetist to conduct "preoperative round with the children showing them he operating theatre anæsthetic room &c The con alescent children will explain the functions of these laces to the new children and a healthy pride in not eing a baby' is nurtured in everyone. Such a round onducted weekly, is well worth the anæsthetist's ime and saves many a stormy induction

But I cannot agree with Dr Mac Keith's views on the remedication of children All sedatives induce a state imilar to mild intoxication with alcohol and whereas his state is accepted by the adult it may produce terror nd a 'nightmare state in the child because of gnorance Children should reach the anæsthetic room rior to surgery either fast asleep or in complete ossession of their faculties

The Hospital for Sick Children,
Great Ormond Street,
London, W C 1

B G B LUCAS
Consultant anæsthetist.

SIR,—Nothing could be more commendable than the urpose behind Dr Mac Keith's article advocating hat children in hospital for operations should be so anaged as to inflict on them the minimum of psychic rauma He emphasises that one of the three main actors producing ill effects is induction of anæsthesia nd in this connection uses such expressions as forced sleep ' feel themselves slipping away under the anæsthetic' and the doctor personally should lead the child from the mother to the operating room These expressions produce in the mind of the reader a picture which one can only hope does not truthfully represent *what goes on at Cameron's hospital in 1953*

It should surely by now be taken for granted that except under exceptional circumstances all children should be given such preoperative medication as will ensure in most cases at least that they will have no memory at all of their visit to the theatre or of induction, thereby entirely eliminating one of Mac Keith's three traumatic factors This can be done of course in a number of ways without resorting to rectal administration which many children dislike quite as much as *conscious induction In the case of tonsillectomy* which represents by far the greatest number of children's operations, I am at present engaged in following up some hundreds of cases after return home from hospital where they are given sodium pentobarbitone (Nembutal) by mouth on a more or less dose-for-age scheme without individual consideration This is not ideal but is practical The investigation is not yet complete but the results to date show that between 90 and 95% of the children under 10 years of age have no recollection of having had an anæsthetic at all, so far as their parents can tell, and that on return home 96% show no nervous upset which is noticed by the parents

This result seems at least good enough to eliminate the necessity of talking to children beforehand about their anæsthetics, except to say that they will be given a drink and will then go to sleep In individual cases in ideal conditions such as nursing home practice, where more time and a constant staff are available, and induction can be carried out in bed, there should of course be a virtual guarantee that the child will have no consciousness of having been to the theatre or of having had an anæsthetic

In fact, the anæsthetist should not do a great deal to allay the child's fears he should see that the *causes of them as far as he is concerned are eliminated* altogether

Windsor DOUGLAS BELFRAGE

INCISION FOR ACUTE APPENDICITIS

SIR—In their article last week Mr Ewing and Mr Monro by implication once again raise the question of drainage following appendicectomy for acute appendicitis. A main advantage of the muscle-cutting incision they find is its suitability for drainage, while Battle's incision is condemned amongst other reasons because of its unsuitability for drainage

This argument seems to me fallacious since the peritoneal cavity should never be drained following appendicectomy whatever the degree of peritonitis It is generally conceded that drainage can do no good and may lead to infinite harm encouraging the formation of fistulæ and adhesions Though it might seem reasonable to drain the subcutaneous tissues when a perforated gangrenous appendix has been removed and free pus is present, I have found this disappointing since often enough a superficial abscess will point perversely at the opposite end of the incision

Many surgeons choose Battle's incision for appendicectomy Retraction *of the rectus muscle should cause no injury and, as Ewing and Monro point out* the incision is valvular and gives the most direct access. Infection of the rectus sheath is a theoretical disadvantage which is not borne out in practice ecause adhesions rapidly seal the layers of the to the muscle Battle's incision ensures t nd 12th thoracic nerves are seen and so submit that hernia formation follow A postoperative hernia is equally rare otherwise identical, incisions—the pararectal approach to the lower end of ureter, and McEvedy's repair of femoral hernia

For these reasons I maintain that Battle's incision should continue to have the sanction of the standard works on operative surgery

Salisbury Hospital Group PHILIP SHEMILT

SIR,—I think that those who have to deal regularly with acute abdominal conditions will endorse the opinions expressed last week by Mr Ewing and Mr Monro

After three years in the tropics, despite the wider range of differential diagnoses, I remain strongly in favour of the McBurney type of approach (with a transverse skin incision), sited in accordance with the physical signs, or Kocher's modification (Rutherford Morison) This applies unless a pelvic location is suspected Naturally, where there is genuine doubt the paramedian incision has a place , but then the operation is a " laparotomy " rather than " for acute appendicitis "

Many of my patients were seen later than is usual in this country *In 12 of the last 25 consecutive cases the appendix* had already perforated In many an abscess had localised, or, in earlier cases, fragile adhesions were forming , and approach through the unaffected part of the peritoneal cavity would have seemed indefensible No one would deliberately approach an appendix abscess by way of the unaffected peritoneal cavity, and I consider that all cases of acute appendicitis should be thought of as potential abscesses , and if operation is performed, the approach should be the most direct route from the surface My experience with antibiotics in intra-abdominal infections has not led to any modification of this view

In commenting on the frequency with which the acutely inflamed appendix is approached in this country by the midline or the paramedian routes, Ewing and Monro state that these approaches have the sanction of many of the standard works on operative surgery On taking a random selection of textbooks from the shelves of a medical school library, I did not find this confirmed, although it may be true of some of the more specialised works Of six textbooks,[1–6] one [5] suggests that the McBurney incision is out of date except for opening an appendix abscess , but the remainder express views which do not deviate from those of Ewing and Monro

London, S E 1 MICHAEL FLINDT

ASPHYXIA IN THE NEWBORN

SIR,—Dr Noel Jackson in his letter (Oct 17) quotes me as follows

> " Writing on artificial ventilation of the lungs, Professor Pask [7] evidently prefers efficient artificial respiration to inadequate spontaneous respiration, for he remarks ' Positive pressure ventilation can be carried out without causing *disturbance in the cardiovascular system* ' "

With the first part of this sentence I agree, but the quotation from my letter seems to have changed rather strangely, for it ran as follows

> " I believe that *many physiologists will be surprised to learn* that positive pressure ventilation can be carried out *at all* without causing *some* disturbance in the cardiovascular system "

Dr Jackson's diagram and explanation of his apparatus worry me If the surgical rubber glove really functions as a rebreathing bag, I think it is too big Furthermore, babies who are called upon to breathe or rebreathe through intravenous needles have my sym-pathy, even though the needles be " fairly large " Th diagram suggests connecting the babe directly to th oxygen supply I think this is unwise and leads to risk of burst babies

Department of Anæsthesia,
Royal Victoria Infirmary,
Newcastle upon Tyne E A PASK

EPIDEMIC VOMITING

SIR,—I read your annotation of Oct 3 and the let by Dr French (Oct 10) at a time when cases of condition were occurring in my practice. They hav increased in number, and I myself became a 2 days ago

Usually there is fatigue, headache (in my own case and in the tissues of the scalp), general aching, and hot cold feelings, followed within a few hours or up to a day two by bilious vomiting Temperature varies from norm to 104°F and the pulse is usually rapid. Occasionally there abdominal pain and slight giddiness, but never true vertig There is no sign of liver tenderness or jaundice, and meningeal signs , but, as in Dr French's series, one appeared which *may or may not* have belonged to the group This was in a woman who developed, after the onset, a 7th and 11th cranial nerve palsy and herpetic on the left side of the palate In the occasional infections the interval between cases has been about 5 da The length of the illness varies from 1 to 7 days.

Ilford, Essex R N C SMITH

CONTRACEPTIVE TECHNIQUE

SIR,—Dr Maung Sein's letter of Sept 26 starts well enough on firm ground but ends in a morass right and proper that he should quote the Americ figures and the immense amount of work done in th country on follow up studies , but this controversy the relative over all effectiveness and acceptability the combined methods of contraception (cap or sh plus jelly, paste, or suppositories) versus the methods (jelly or paste or suppositories or condom alone) is a very old one and still rages Unfortunate simply to quote pregnancy rates means very little, is necessary to know quite a lot about the back of the various series before it is possible to judge wh the comparison is a fair one (e g , number of nullip age range , previous fertility , duration of use , so economic, educational, and religious background, so forth) Still more unfortunately one cannot al discover these important facts even in the original paper, and this applies to a large extent to papers published on ' Preceptin '

In any case all this talk about pregnancy rates is confusing the original issue I was not concerned pregnancy-rates but with one particular patient, a hi fertile, sick woman, most willing to coöperate with medical advisers in every way , in fact she coöpera with them so well that she used preceptin when was advised to do so, with disastrous conseq having previously used a combined method with suc Dr Maung Sein will have a job to convince me *all other things being equal*, it is possible to offer a as complete protection against pregnancy by giving a paste or suppository to use alone as by providing with a mechanical barrier to prevent direct insemin of the cervix plus a chemical one to kill the sp This is not to deny that preparations such as and various suppositories have their place in con tion, and, as I said in my letter of Aug 15, this paste will in time find its correct level of use It will undoubtedly be of value in the first of Dic categories but I very much doubt if it will be *the* an for many in the other three

The last part of Dr Maung Sein's letter had be left unanswered—not because it is unanswerable because it starts a number of irrelevant hares

THORIUM DEPOSITS IN THE LIVER

Sir,—I welcome last week's article by Dr Berenbaum nd Dr Birch who summarise recent reports on the ore dangerous side-effects of Thorotrast and empha se the difficulty in tracing the cause of death in patients ho received one single injection of thorotrast about 20 ars earlier

Before thorotrast was marketed I carried out extensive periments on rabbits and rats which were observed for months or more [1-3] The results of these investigations ere summarised in an answer to your annotation on e danger of thorotrast 15 years ago [4] Most of the thological reactions following thorotrast injections ere known already in 1032 (the year when thorotrast as marketed) and although the observation time in y series was far too short for such changes as aplastic emia and malignant tumours to have appeared even those early studies due mention was made of the ssibility of these complications At the same time a arning was sounded against the use of thorotrast in an Perhaps this warning was instrumental in reducing e number of fatalities on the Continent

CERVICAL SPONDYLOSIS SIMULATING MOTOR-NEURONE DISEASE

Sir,—I have read with interest the article on cervical ondylosis by Dr Liversedge and his colleagues in ur issue of Sept. 26 It strikes me that some of the nfusion in the early diagnosis of their cases might have en avoided if the jaw jerk had been recorded I can e no mention of this having been done Surely a ormal jaw jerk in the presence of otherwise brisk ndon reflexes would cause one to hesitate in the iagnosis of motor neurone disease ?

Johannesburg South Africa ROY MORRIS

CHRONIC BRONCHITIS

Sir,—Dr Oswald and his colleagues (Sept 26) have iven us some important clues in the search for the cause f chronic bronchitis. Even though there are still many aps in our knowledge it is essential that we should pply the facts we already know Dr Oswald emphasises he importance of the quality of the inspired air Although e can hardly hope to affect our damp cold winter imate there are several ways in which the chronic ronchitic can be given better air to breathe.

Smoking is undoubtedly one of the chief irritants in hese patients. It is unusual to find one who fails to otice distinct improvement in his symptoms when he as stopped this habit. I am surprised how rarely atients have been advised about smoking by their wn doctors The majority of patients with chronic ronchitis will stop smoking provided they are told f the importance of doing so in strong enough terms. consider tobacco is poison for a chronic bronchitic nd I tell him so

Last winter's fog killed 4000 people in London, the ajority of whom had chronic bronchitis In the late ar the remote chance of a gas attack produced elaborate nd expensive precautions on a wide scale yet we main relatively complacent in the face of these recurrent s-attacks, which kill many of our citizens yearly ong-term plans to lessen air pollution are essential ut until they are effective the patient with chronic ronchitis should be given similar protection from fog that which the war time civilian was given from oison gas. The sufferer from chronic bronchitis usually ays at home during fogs, knowing his risk of relapse Could not a room in his house be made fog proof just as each civilian learned to make one room gas proof in the war ? Civil defence authorities would probably be willing to help and advise He should also be advised to wear a light mask, at any rate when having to go out of doors

It is time that we paid more attention to the purity of the air which our patients breathe and endeavoured to prevent them from consuming their own and everybody else's smoke

THE PLACEBO

Sir,—Both the contributors on this subject in your issue of Oct 17—Dr Barham Carter and Dr Handfield-Jones—have omitted to ask the highly pertinent question Who needs the placebo ?

Our patients do not demand placebos I have yet to meet the patient who asks : Doctor may I have a placebo an inert inactive substance ?' Patients ask us for help though often in an inarticulate way difficult to comprehend yet it is our task to try to understand the patient's needs For instance Dr Barham Carter's patient who had a urinary infection probably venereal in origin, and who ten years later was still on methylene-blue was obviously not freed from anxiety about his illness and needed more treatment, not necessarily with methylene blue But again obviously methylene-blue for ten years was better to him than nothing

If the doctor's inner hearing is not acute enough or if his understanding of the patient's need is barred by bias or prejudice, or if the patient arouses anxiety or guilt within the doctor, then the doctor only too often has to prescribe a placebo because he needs it for his own reassurance And this is the true function of the placebo It does not serve the patient's, but the doctor's need whatever the excuse may be with which it is prescribed.

The term 'placebo then needs re-definition The definition given by your contributors (an inert drug given to please or satisfy the patient) is contradictory in itself Firstly no drugs not even water or salt are truly inert secondly all treatment is given to please or satisfy the patient What greater pleasure or satisfaction could we give the patient than to free him from disability or illness ?

Treatment by a placebo is rightly contrasted to scientific treatment—that is to treatment that is fully understood in its implications but many forms of treatment which are considered scientific in themselves such as electro-shock insulin shock or antibiotics, may well be given as placebos as much as the reassuring pat on the shoulder and the red tonic

It is not enough (as Dr Barham Carter thinks) to take an adequate history or make an adequate physical examination We must also try to understand the inner needs and longings of our patients, or else all well meant treatment with fine names after high-sounding diagnoses will be a placebo for the satisfaction of our own needs.

The people that come to see us for help are ill and we all retreat in illness, in ill-adaptation to a state of infantile narcissistic dependency where we long for satisfaction and comfort by medicines diets, cooling drinks soothing broth as if illness aroused memories of early infantile dependent days when mother's breast the bottle, the dummy or our own thumb gave us similar oral satisfactions

Cabot's remark (quoted by Dr Handfield-Jones) that babes are not born with the desire to take a drug for every symptom is quite wrong The babe needs very much oral satisfaction for his symptoms, and the eternal babe within us, that comes into the forefront in illness very often needs satisfaction by mouth. Such longings have to be considered in scientific treatment, too, or else the scientific view would be incomplete We need not feel ashamed or guilty because, in full knowledge of their effect, we have prescribed preparations which have no easily definable pharmacological action upon an isolated organ or system

Let us define then (and reject) any treatment that is given without the doctor fully knowing and understanding what he does by treating the patient—as a placebo for the doctor

Southall, Middlesex. M B CLYNE

SIR,—Dr Barham Carter (Oct 17) is wrong, according to all principles of psychotherapy, to give psychoneurotic patients a placebo as "a material sign to establish confidence so that they will benefit from the real helpful psychotherapy that follows" Once it has been established that the patient does not require medicinal treatment, he will create in this patient, not confidence, but the conviction that there is some medicinally treatable condition If the patient already believes that "words can't help my trouble," he makes his job of giving the patient effective psychotherapy almost hopeless The exhibition of placebos is a regression to pre Freudian days It could even culminate, as I have experienced, in this trend of "reasoning" the patient will not accept the psychogenic basis of his disorder, therefore, if I help him to convert his psychoneurosis into an organ-neurosis, I can treat this by drugs If we are dealing with a somatopsychic disorder—e g, asthma mucous colitis, duodenal ulcer, neurodermatitis—palliative medicinal treatment is, of course, indicated, and this should be fully explained as palliative Drug treatment in psychiatry is also indicated in the well-recognised and defined syndromes—e g, vegetative imbalance or concomitant emaciation—but again this requires full explanation to the patient, as to what it is intended to produce or effect But placebos ? No !

POSTURE, BACKACHE, AND HEALTH

SIR,—In your issue of Oct 17, Mr W E Tucker discusses human reaction as illustrated by the manner employed by a person in his standing and sitting Now, in standing and sitting, as in all the variations of human reaction, the relationships between the various parts of the person are guided and controlled by means of sensory communications known medically as kinæsthesia The way a person adjusts himself as a whole depends upon how well kinæsthesia works, and this again depends upon how the communicating mechanisms are adjusted When the means of communication are badly adjusted the standard of kinæsthetic guidance is low, when they are well adjusted, the standard is high Mr Tucker must be aware that Rudolph Magnus demonstrated that the adjustment of the animal as a whole enabling the sensory and motor communicating mechanisms to operate at their best and, therefore, in a reliable way, was an adjustment which he showed was associated with a certain relativity of the head to the neck Sherrington also acknowledged the importance of the head neck relativity in connection with knowing how to control human reaction In the light of the views of these great experimenters, it must be clear that where a person does not react in accordance with a principle enabling him to use the psycho-physical mechanism or self in a way associated with a control over the relativity of the head to the neck ensuring a rising standard of kinæsthetic sensory appreciation, he is bound to do injury to the working of the self and, therefore to

One of the consequences of failing to observe th principle is that we form wrong beliefs about how th self works and are led along roads to knowledge whi are misleading The burden of retracing our steps alo these wrong roads grows the greater the longer w postpone the admission that wrong means will neve enable us to gain the best possible control over h reaction in its many and complex variations

Bolton, Lancs. MUNGO DOUGLAS

PERIODIC MEDICAL OVERHAUL

SIR,—Sir Adolphe Abrahams (Oct 24) considers that th purpose of the periodic medical overhaul is to the patient *when well* If by "well" he means health then by definition the medical overhaul will reve nothing If by "well" he means that the patient sa he feels well, many diseases are symptomless in th early stages and many otherwise sensible people some symptoms—e g fatigue, cough, obesity—as Their statement that they feel well does not mean th are healthy

My criteria for periodic medical overhaul are it should be done at appropriate intervals and that should be thorough The presence or absence of s is immaterial

Reigate Surrey ERNEST H CAPEL

HYPERTHYROIDISM IN CRETINS

SIR,—Dr McGirr and Dr Hutchison (Aug 22) sa that, in their opinion, the terms hypothyroid, euthy and hyperthyroid should continue to refer to the clin state of the patient and should not be used to refer to the functional state of the thyroid gland

I have observed [1] an endemic cretin with these func tional thyroid data

Basal metabolic rate (B M R) + 18%, protein bo (P B I) 8 9 µg per 100 ml ; serum protein (Pullfrich) 7 per 100 ml, blood cholesterol 105 mg per 100 ml, iodine uptake of the thyroid 87% after 2 hours, 81% 24 hours, follicle stimulating hormone in urine + 10, mouse units per 24 hours (Gorbman's method), pregnan 4 5 mg per litre (nearly 15 days after previous recurrence)

This patient received 20 mg of thyroid stimulating (T S H Armour) daily on three consecutive days, and this we obtained these values B M R + 30%, P.B.I 9 25 per 100 ml, blood cholesterol 93 mg per 100 ml

These changes show a ready secretion response of thyroid to treatment with T S H and a ready response to the increase of thyroid secretion

Recently in our hospital thyroidectomy was done non endemic goitrous cretin, whose thyroid fun data were

B M R + 11%, P B I 9 11 µg per 100 ml, thyroid of I^{131} after 1 hour 28 8%, after 24 hours 34 1% (H ratio 60%), blood cholesterol 133 mg per 100 ml logical examination showed many areas with indication hyperfunctioning adenoma

Why should we not call these patients "hy thyroid," as we call all other patients with such chemical data ? Of course we do not judge these pa to have Basedow's disease

Some workers suggest that the cretins we have cribed were probably hypothyroid in their early y and became hyperthyroid later

We answer

1 Nearly all endemic cretins we have studied showed high B M R a high I^{131} uptake, a high conversion rate, forming of labelled thyroxine, and a low P B I But P B I value was never as low as in true hypothyroidism (average value in 21 patients was 4 54 µg per 100 ml)

2 We do not believe that their high radio iodine is due to a low iodine availability, because normal people the nurses eating the same food, have a normal thyroid u

---

1 Costa A *Rass biochim sci* July, 1953, p. 189

We cannot admit that a thyroid so insufficient as to cause ere signs can later correct spontaneously and so frequently

We think we have proved that endemic and non-endemic tins can be sometimes hyperthyroid On the other hand fact that their thyroid is failing to produce or to liberate ficient hormone to meet the needs of the tissues is still proved

According to us views on the pathogenesis of cretinism ght to be revised; these patients should not be considered othyroid because of their goitre or some functional airment of their thyroid or because they seem to hypothyroid

Mauriziano Hospital,
Turin Italy

A COSTA

THE DRUG BILL

SIR,—Since I entered general practice I have con entiously learned the official names of drugs and have scribed *National Formulary* preparations for the vast jority of patients, under the impression that by ing so I was helping to economise I have argued th patients who have been used to a proprietary ug and I have insisted on their accepting the inferiorly rketed product in cases where I now find it would ve been more economical to comply with their sonable request

How many other reputable manufacturers I have ghted directly or by implication I do not know t as a general practitioner I beg their pardon and ure them that if in their circulars, they give a clear tement that their product is as economical as the F preparation in total cost I shall try not to make same mistake again

G P

SPLENECTOMY IN ACUTE IDIOPATHIC THROMBOCYTOPENIC PURPURA

IR—At the surgical congress held in Berlin in 1923 d again in 1924 I expressed for the first time the nion that one should strictly discriminate from the ndpoint of ætiology and splenectomy between acute d chronic idiopathic thrombocytopenic purpura (I T P)[1,2] My contention then was based partly on my erience in Schloffer's clinic in Prague, where on the ommendation of Kaznelson the first splenectomies re performed for I T P and partly on the first 20 blished cases and 4 additional cases of my own at the gical clinic in Kiel Of these 24 cases, 4 were of the te type and of the latter only 1 survived splenectomy n 1 of the 3 unsuccessfully treated acute cases I cribed extensive necrosis of the vertebral bone rrow I attributed the thrombopenia to this finding ch was later confirmed by other workers—for example midt in Würzburg Eugene Fränkel in Hamburg l Ghon in Prague (personal communication)—but this on was the subject of controversy at the conference of German Pathological Society in 1927 No findings ilar to mine have been described since

y recommendation to exclude acute cases of I T P m splenectomy was generally adopted, and my clinical ervations confirmed, till Anschütz[3] rejected my views d advised early splenectomy in acute cases, on the umption that they differed only quantitatively and qualitatively from the chronic cases He admitted ever that the operative mortality in the acute group s as high as 70–80% Nevertheless many textbooks of matology and medicine nowadays adopt my view ht and advise against splenectomy in the acute form I T P This view is supported by the recent studies of fanini and Dameshek,[4] who suggest that it is now sible to recognise certain significant differences in the immunological mechanism between 'acute and chronic" types of I T P They also say that an immediate result of these findings has been that of emphasising the necessity of the careful assessment of the clinical and laboratory features of each case of I T P with particular reference to its acute or chronic nature This has considerable bearing on the decision whether and, if so when splenectomy should be done' It seems that these studies vindicate my opinion, expressed thirty years ago that acute I T P should not be treated by splenectomy in contrast to the chronic type which usually responds to this operation

One aspect of the purpura problem does not seem to be clarified by the latest work—namely, why females are predominantly affected I used to explain this fact on the basis of the periodical changes that take place in the female vascular endothelium—changes which may be caused by toxins perhaps Schick's menotoxins, and which render the endothelium more vulnerable to other factors that operate in both sexes I wonder whether this theory is still tenable

TREATMENT OF RHEUMATOID ARTHRITIS WITH PHENYLBUTAZONE

SIR,—Since our paper appeared in your issue of June 20 1953 Mr R G Carpenter F.S.S has drawn our attention to an error in the value of χ^2 in tables I and II Values of χ^2 should be:

Table I: χ^2 (with 3 degrees of freedom) = 12·77 $0{\cdot}001 < p < 0{\cdot}01$
Table II χ^2 (with 3 degrees of freedom) = 7·07 $0{\cdot}05 < p < 0{\cdot}1$

Thus whereas the subjective assessment gives a comparison highly significant in favour of the drug the *objective assessment shows only a suggestive difference* between the drug and control groups. As we laid more stress on the subjective than on the objective assessment we do not consider the validity of our conclusions to be substantially diminished

HYALINE MEMBRANE IN THE NEONATAL LUNG

SIR,—I read with interest the article by Dr Claireaux (Oct 10) which confirms the importance of hyaline membranes as a factor in neonatal death I would like to make two comments Firstly aspiration of amniotic fluid by a fœtus in utero produces uniform partial expansion of all alveoli Should such an infant survive for a short period after birth sections of the lungs show inspired air pressing squames and debris of the amniotic fluid against the alveolar walls and the individual squames can usually be identified. Dr Claireaux and previous workers agree that the predominant site of the hyaline membrane is not the alveolus but the alveolar duct I think these observations make it unlikely that any constituent of amniotic fluid plays a major rôle in the formation of these hyaline membranes Secondly the hyaline membrane produced experimentally in the rat was the result of the intratracheal injection of 1 ml of concentrated hyaline material and appears to bear little relationship to the postulated aspiration of normal amniotic fluid by the fœtus

In his comments last week Dr Emery does not amplify his belief that intrapulmonary vascular changes are major factors leading to formation of hyaline membrane but this theory does not appear to account for the nuclear remnants found in some lungs by Dr Claireaux and myself It may well be that hyaline membranes found in diverse conditions are due to more than one pathological process.

Medicine and the Law

Praise or Blame at Inquests

On Sept 23 a coroner's jury at Guildford, having inquired into a fatality caused by an accident to an electric train at Guildford Station, returned a verdict of accidental death and added a rider exonerating the motorman from blame At a subsequent inquest at Guildford[1] the coroner spoke of this rider as unfortunate and reminded the jurors that they must not introduce into their verdict anything which may tend to decide the question of civil liability

The new Coroners Rules, which came into force on March 1 last, are quite clear upon this point and, though already familiar to coroners, may need repeated emphasis in any summing up to a jury The effect of the rules is that the proceedings and evidence at an inquest must be directed solely to ascertaining (*a*) the identity of the deceased, (*b*) how, when, and where he came by his death, (*c*) the persons, if any, who (if the findings warrant it) might be charged with murder, manslaughter, or infanticide, and (*d*) the particulars required for registration of the death "Neither the coroner nor the jury shall express any opinion on any matters other than those referred to" in the foregoing provision, though an exception may be made for any recommendation designed to prevent the recurrence of similar fatalities "No verdict," moreover, "shall be framed in such a way as to appear to determine any question of civil liability"

This restriction follows the recommendation of the council of the Coroners Society in the draft Rules of Procedure of 1937 Chapter VII of the report of Lord Wright's Committee had drawn attention in the previous year to the apparently growing practice whereby interested parties made use of an inquest in order to elicit facts which might bear on civil liability but which were strictly irrelevant to the issue before the coroner The committee had been told that parties were frequently represented at inquests with a view to securing a rider exonerating the person concerned or placing the blame on someone else The advocates, said a witness from the Law Society, seemed to be turning the coroner's inquest into a county court or High Court and raising small questions of negligence which might bear on the award of damages, thus prolonging the proceedings at an inquest and covering unnecessary ground A representative of the county chief-constables quoted a coroner as saying that inquests were "becoming happy hunting-grounds for gentlemen who come here to pick up material on the chance of getting damages out of one party or another"—clearly an abuse of the coroner's court

As the Wright Committee observed, the coroner's court is not equipped for such an inquiry The Home Office had cited a case in which a coroner had given directions to a jury on a question of workmen's compensation law—whether a fatal accident did or did not arise "in the course of the workmen's employment" The Ministry of Pensions had given evidence of inquests being allowed to discuss the extent to which war service had contributed to the death In a subsequent chapter the Wright Committee laid similar emphasis on the need of avoiding verdicts or riders of censure or exoneration It was contrary to natural justice that persons might find themselves condemned in proceedings to which they were not parties and in which their conduct was not in issue

Medical practitioners who happen to be summoned as witnesses at an inquest will note the significance of the new rules They may be saved a protracted examination on some question of civil negligence

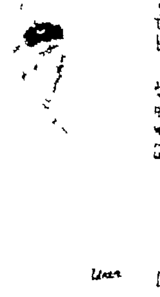
Obituary

ROBERT TENNENT

M.B Glasg, F R C S E

The death of Mr Tennent in Stirling on Oct 9 deeply affected a wide circle of friends

He was born in Strathaven in 1890 and received early education at *Hamilton Academy, of which he* a distinguished pupil From the University of he graduated with honours in 1914, a few months b the outbreak of the first world war, throughout he served in the Royal Navy He was granted to take the fellowship of the Royal College of Surgeons of Edinburgh and this he did in 1917 After the war he was appointed to the staff of the Royal Hospital for Sick Children, Glasgow, where he was junior to the late Mr Alexander MacLennan, whom he also assisted in private practice His appointment to the Victoria Infirmary soon followed, and there, after some years as first assistant to Mr R B Carslaw, he was given charge of wards in 1927 at an unusually early age Making this his chief interest and regretfully discontinuing his work at the Sick Children's Hospital, he entered into a period of very active hospital and private practice, terminated by resignation in 1949, the end of his long and association with the Victoria being forced upon his failing health



In 1924 he accepted the invitation to become surgeon to *Falkirk Infirmary*, and his connection this hospital was also a very happy one, he the responsibility and credit for the planning of Royal Infirmary which was opened there in 1932, was therefore understandable that he should *to do some work there even after his retiral from* in Glasgow

Tennent's work in the Victoria Infirmary earned him in Glasgow and throughout the West of reputation for work of the highest quality, in the fields of abdominal and thyroid surgery, in *latter he achieved particular eminence, and it is* table that he did not live to carry out his intention publishing his results Although he latterly tended be more circumscribed he was so much the surgeon that any new method received consider and underwent trial at his hands, he had been example, one of the first in this country to Harris technique for prostatectomy Above all, T was characterised by a dexterity and gentle hand which gave him results surpassed by few He surgeon who could make surgery look easy, and celerity, combined with a natural aptitude for made his life exceptionally full and busy

Tennent taught well and was for many years a lecturer in surgery to the university, and in his years examined for the final M B CH B Proba unofficial teaching which he did as an assistant gave him the greatest pleasure For many gathered round him on Saturday mornings a large of final year men, and his ward rounds then delight Many a student learned as much surgery his informal, anecdotal talks as from a series of sedate clinics, and these tutorials will live long memories of those who attended them He must been a most kindly examiner, and it is difficult to any candidate being other than at ease with him; it is equally difficult to believe that his intuitive ment of a man was wrong if he considered him a future doctor

In spite of all his activities, Tennent found many interests apart from his profession Angling his first love, and he knew intimately most of the his native country his friends were legion among untrymen in all walks of life. His love of country ings and country folk was exemplified by his wide owledge of Scots ballads, which his retentive memory abled him to recite freely, and it was another of his ots attributes that he could quote the Old Testament length and with accuracy.

Robert Tennent was a fine surgeon; he was also a e man, and this side of his character was most impres ve to those who were so fortunate as to be his friends. e was generous to a fault, and his help was always ailable to patient and colleague alike at no matter hat sacrifice of his time and energy. Many young men ve their start in general practice and surgery to the nselfish help given by him.

The second world war made increasing demands on m at a time when normally he might have been pected to begin to enjoy more leisure. These demands ere met in full but only at a cost, and in 1947 came e first signs of the vascular disorder which made it ecessary for him to modify his activities. Shortly after is he went to live in Dunblane and gradually made is severance from Glasgow well nigh complete.

He leaves a widow, three daughters and two grand ildren, of whom he was exceedingly proud. He will remembered with gratitude by many, with affection many, whether they knew him as the surgeon, the iend, or as both.

J. P. G.
R. G. H.

WILLIAM ELDON TUCKER

B.A., M.B. Camb., F.R.C.S.

Dr. Tucker died on St. Luke's Day, Oct. 18, at the e of 81, in Bermuda, where he had practised for nearly lf a century.

From Bermuda he went to school at Port Hope in nada, where he was a classical scholar and head of the hool. In 1891 he came to this country to study edicine at Caius College, Cambridge. He soon won fame the Rugby world, playing for Cambridge and England. ven in the 1920s many of the college servants remem ered his feats of strength, for he had gained the putation of being, among other things, one of the ongest men ever to be at the Varsity. He captained e Cambridge XV in 1894, the same year as the late M. Carey captained Oxford, and the result was a draw. th men played in the England team together with ch great players as A. F. Todd, S. M. J. Woods, and ank Mitchell, and were firm friends. It was a coin dence that Carey and Tucker were born on the same y, Aug. 17, 1872, the one in the island of Guernsey d the other in the island of Bermuda.

Tucker qualified in 1899 and held house-appointments St. George's Hospital until 1902, when he returned to muda and started in general practice. Before his ival only two major operations were known to have en performed in the islands. Through his efforts, wever, and those of the late Dr. Trott, several hundred jor operations were performed at the hospital each ar.

During 1914–19 he acted as surgeon to the Military spital, Bermuda. On one occasion, when a ship-load frost bitten West Indian troops arrived from the rth in winter, he performed about 150 amputations thin a month. As motor-cars for general use were permitted in Bermuda until 1947, he visited his tients either on horseback, bicycle, or horse-drawn rriage.

As a practitioner of the old school he was loved and spected throughout the islands. Although he was a n of strong personality and definite views, thanks to s gentleness and frankness he made few enemies but ny friends. In later life he became crippled with eo-arthritis, and in 1949 he had to retire from practice, t he bore his disabilities with a stout heart. The Royal llege of Surgeons of England conferred their fellowship him in April this year, and with great pride he made e journey over by air to receive the honour which put e seal on his full and useful life.

He leaves a widow, two daughters, and two sons, one whom is Mr. W. E. Tucker, F.R.C.S.

Sir EWEN MACLEAN

Sir William Fletcher Shaw writes:

I have a vivid recollection of seeing Sir Ewen Maclean for the first time when I was taken, as a visitor, to a meeting of the Representative Body of the B.M.A. in Liverpool during the stormy time of the Lloyd George National Insurance campaign. His tall, slim, gracious figure, with the long Scottish head and marked features and the pleasant clear voice, seemed almost boyish, but he knew his subject backwards, and had complete control of what might have been a very unruly meeting: if I remember rightly, it was after the Smith Whittaker resignation. I was much impressed, but little thought at that time how well I was to know him later. My first personal contact was at the end of the first war when I was elected a member of the Gynæcological Visiting Society. In this band of friends he was one of the leaders, always full of fun and ready to laugh at a joke against himself, an attractive after-dinner speaker who was popularly supposed to act up to the motto "Where I dines I speaks"; never ruffled, always kindly and friendly to juniors. I found his most attractive feature in his readiness to discuss any subject about which there was a difference of opinion—never didactic or blustering, always wishful to convince by pure reason.

It was this feature which made him so valuable to the Royal College of Obstetricians and Gynæcologists in its formative and early days. He was one of the four who formed the first committee to explore the possibilities of its foundation. In those days, perhaps, he contributed the least largely because so much had to be done by correspondence, and he never wrote long letters, at any rate to me, nor would he employ a secretary; but he attended every meeting and turned clear common sense on to every proposal. Towards the end of this formative period and during the first three years of the life of the college, when we were torn by personal dissension, he was invaluable. I had become honorary secretary and the recipient of stormy correspondence from all sides, often fearing that the next meeting would blow the fragile nursling sky high; my one anxiety was to have Maclean present, the one always to be relied upon never to lose his temper or to use an expression which would irritate either side, but talking horse sense until both sides saw it and the storm quietened.

He became president himself at a fortunate period for the college when his peculiar gifts had full play. Personal quarrels had now disappeared, and, even more important, under the presidency of his predecessor, Fairbairn, the friction between London and the rest was finally settled and the college was ready to bound forward again and to earn its charter and the title "Royal."

His gracious manner, attractive appearance, and able speaking, his love of people, and his large acquaintance with public men from his former position in the B.M.A. and through his brother Sir Donald Maclean, were just what the college required to bring it into public notice. During this period the Minister of Health, for the first time, formed a small advisory committee which Maclean was asked to join. Since then, whatever form this committee has taken, his successors as presidents have been members; but I always thought this first invitation was due as much to his personal qualities as to his office. So too he laid the foundations for the "Royal" and the charter, neither unfortunately arriving during his presidency—the "Royal" only two months after he had laid down office and the charter only in 1947 because the war intervened just as it was on the point of being granted. But they were really won in his time.

The three years of his presidency was perhaps the happiest period of my secretaryship; he was so easy to work with, never any personal rancour, all differences of opinion discussed in a friendly atmosphere and a *via media* found, no desire for personal aggrandisement, always the good of the college. We dined together in London most weeks and settled our line of action in the many problems which arose, and not once was there the slightest jolt to our friendly coöperation. During the five years of my presidency he remained on the council. This was the difficult period of the early war years with completely new problems and new contacts. He was a tower of strength on which I could rely, never usurping the position he had just vacated, always ready with shrewd helpful advice.

Others will write of his many other activities. I record merely what the college as a whole and what I personally owe to him. A great gentleman and a true friend.

Notes and News

FROM MYSTERY TO MASTERY

Of the five Heath Clark lectures on Man's Mastery of Malaria given this week at the London School of Hygiene and Tropical Medicine by Dr Paul F Russell, of the Rockefeller Foundation, the first was on Monday when Sir Neil Hamilton Fairley, F.R.S, presided over a large gathering Dr Russell admitted that his title was optimistic, for malaria still does immense damage to mankind, but he hoped it was not too exuberant the word mastery implied power to defeat the disease and therefore responsibility for its control

Devoting his first lecture to the ætiology of the disease, he said that, when man first appeared, the mosquito was already a well established form of life and had probably already formed its partnership with the protozoon Prehistoric man, at least in some warmer regions, almost certainly suffered from malarial ague, and the disease was to be found in the early historic records of Egypt, India, and China Hippocrates, who described the quotidian, tertian, and quartan fevers, associated the disease with marshy districts he did not spot the intermediary mosquito, but, on the other hand, some physicians today had their eyes so firmly fixed to microscopes that they could not see the significance Hippocrates noted in "airs, waters, and places" The word *malaria* (bad air) was used in Italy during the Middle Ages, by doctors and laymen alike, for the cause of intermittent fevers—not for the illness itself In some parts of Italy the alternative *cattivaria* was used, but *malacqua* (bad water) never had wide currency The miasma from swamps, and even from hill streams, was held responsible for the fever, and as early as the 1st century B C a Roman writer had spoken of the noxious effects of small creatures, invisible to the human eye, which come out of the marshes Various writers were puzzled by the regular rhythm of the fever, which made it clinically unlike an ordinary toxic or inflammatory state and more suggestive of a living multiplying organism Before 1831 Rasori had scored a bull's eye with his account of the behaviour of this hypothetical organism

In the laboratory, examination of the blood showed granules of "malaria pigment," and the malaria parasite was in fact probably seen by Meckel, Delafield, and others In 1876 Joseph Jones, in New Orleans, recognised malarial blood on a stained garment and claimed that by examining the blood he could tell that the patient was in a paroxysm of malaria Laveran made his conclusive observations in 1880, but they were not generally accepted for some years Thus at a meeting in the United States in 1886 Osler expressed grave doubt about Laveran's bodies being the cause of malaria, but he was shaken by the discussion, deferred his Canadian holiday, found the crescentic forms and declared that he had been taught the folly of scepticism based on theoretical considerations

But still nobody knew exactly how natural infection with malaria occurred Over the centuries, the inhabitants of parts of Italy and Africa had associated fevers with mosquitoes and even (as Richard Burton reported in 1856) with their bites Lancisi in 1719 thought that insects from the marshes possibly conveyed to man their own bad humours It was in April, 1894, that Patrick Manson, walking along Oxford Street, told Ronald Ross of his theory that mosquitoes carry malaria parasites just as they carry filariæ This was 14 years after Laveran's discovery, but Ross, working in the tropics, had never seen malaria parasites till Manson showed them to him, for the use of microscopes in the tropics was negligible till this century Ross now went back to India—with a microscope and great zeal, but with little knowledge either of the literature or of the mosquito His observations, and those of Grassi in Italy, provided the conclusive proof And recently, said Dr Russell, the studies of Prof H E Shortt and Prof P C C Garnham at the London School of Hygiene and Tropical Medicine had brought the ætiological story to a climax The malaria parasite could now be followed (but for a few small hiatuses) from the mosquito's beak, through the human body, and back into the insect

The last of Dr Russell's five lectures, entitled Malaria and Society, is being given at the school today, Friday, at 5 30 P M

VIRUSES IN MEDICINE

T[illegible] current issue of the *British Medical Bulletin* deals [illegible]uses in medicine Dr C H Andrewes introduces the [illegible]nd points to the many important advances made in this field by British workers Sir Macfarlane Burnet contributes an article on the ecology of virus diseases, contrasting those which produce life-long immunity with those in which repeated or persisting infections occur Prof Wilson Smith shows how *simple viral immunology* can be, and Dr E W Hurst indicates the difficulties confronting anyone working on the chemotherapy of virus diseases Dr Forrest Fulton complains that in the hierarchy of those who work with viruses it is customary to allot a very humble place to the craftsmen who concern themselves with the minutiæ of technique So the editors of the bulletin cannot be accused of doing so they have rightly given prominence to Dr Fulton's article techniques used in the study of viruses Apart from the general topics, there are articles on specific virus diseases smallpox and related infections (Prof A W Downie and Dr A Macdonald), recent advances in poliomyelitis (A J Rhodes), Coxsackie viruses (Dr J O'H Tobin), the common cold (Dr C H Andrewes), the viruses of epi influenza (Dr A Isaacs), mumps (Prof E T C Spooner yellow fever considered as a problem in epidemiology G W A Dick), infective and serum hepatitis (Dr F O MacCallum), the psittacosis lymphogranuloma group viruses (Prof S P Bedson), Q fever in this country (Dr M G P Stoker), the postinfection encephalitides (Dr E Hurst), and veterinary diseases of medical interest (Dr A Gledhill)

THE MAGNUSON REPORT

Last year the report of the Presidential commission the health needs of the United States was presented by chairman, Dr Paul B Magnuson Vol I, giving the find and recommendations of the commission, was publis last December[1] Volume V has now appeared,[2] and sets the testimony of witnesses at regional public hearings 8 large cities in the United States The narrative is p under the headings of the Consumer of Medical Service Professional Groups, Medical Care, its Provision and Payment, Professional Education, Health Problems Va and Rebuilding Health and Usefulness There are also of witnesses, case histories, and a useful index

DEFECTIVE OR DEAF

Many children who are born deaf or become deaf at early age—and especially if they develop emotional dis ances as a result—are certified as mentally defective remain in institutions for the rest of their lives. Dr Minski, whose annual report from Belmont Hospital attention to their fate, describes a small unit which he has up for the study of such children

The unit has been financed for a year by the South-Metropolitan Regional Board, from their research funds, King Edward's Hospital Fund for London have given a towards the equipment—including such things as audio gramophones, and headphones The unit opened last M taking six children Miss Edith Whetnall, who besides an aural surgeon is an authority on deafness, is taking in the work, and Dr Minski supervises the clinic from psychiatric point of view The team includes, besides electro encephalographer, a psychologist, a teacher of the deaf, a mentally trained nurse, and four children's visors, and it also has the help of the occupational ther

Such misdiagnosed children, being unable to speak, give picture very like mental defect Yet if their disability been diagnosed early they would have responded to training in schools for the deaf, and have been able to live normal lives In the unit, the six chosen patients are studied psychologically and also by encephalography, psychogalvano and audiometry Their response to teaching and supervision is also recorded The aim is to devise tests which will distinguish the mentally defective from the deaf, which also, no doubt, will measure the degree of defect in those who have both disabilities This, of course, take some time, but meanwhile the team have been encouraged to find that the brightest child in the group, a boy who has already spent six years in an institution for defectives, is merely deaf and not mentally defective at A practical problem is that a child like this needs inte education, to help him to make up his leeway, before he ble to benefit from the teaching in an ordinary school for the eaf Dr Minski suggests that a special school is needed for uch children, where they can be given more individual and ntensive training than is possible in a school for the deaf The regional board are approaching the Ministries of Health nd Education about the possibility of providing such a school ertainly children so unnecessarily handicapped need some pecial consideration and help

NEW MEDICOLEGAL JOURNAL

The *Journal of Forensic Medicine*[1] a new quarterly ponsored by the Medico Legal Society of Johannesburg nd edited by Dr H. A Shapiro is intended to serve an nternational need by providing space for papers on those iverse and apparently unrelated *fields of scientific inquiry* which together constitute forensic medicine An editorial in he first number suggests that the present dispersal of papers n this subject is undesirable and interferes with their ready ppraisal by those who can appreciate their medicolegal ignificance

The first number comprises eight papers K M Bowden, of Melbourne writing on Sudden or Unexpected Deaths in nfancy analyses 320 such cases, 216 of which were of patients nder the age of one Acute infection of the respiratory tract common cause of death may be readily overlooked if the ung parenchyma is the only portion selected for histological tudy for disease may be confined in early cases to the larger ronchi Acute epiglottitis or acute laryngitis may be respon ible for extremely rapid death from intense inflammatory welling In 27 cases (8·4% of the total) a non-specific acute yocarditis was found ; this might have been overlooked had ot the tissue been examined histologically Widespread yocarditis was found in one baby who died on the first ay of life so it was concluded that the disease had been resent in utero Two episodes of acute non-specific myo arditis were observed in Melbourne—the first in 1949–50 t the time of an outbreak of poliomyelitis and the other n 1952. This disorder has also been found in association ith inflammatory changes in the meninges (meningomyo arditis) and with inflammatory changes in the upper part of he respiratory tract

Lester Adelson of Cleveland Ohio discusses Possible eurological Mechanisms Responsible for Sudden Death hile there are valuable papers on the Estimation of Stature rom the Long Bones by E N Keen, of Cape Town and h the Estimation of Age from Cranial Sutures by Ronald nger of Cape Town L. Prinsloo of Durban reports how the eletal remains were successfully identified in the Howick alls Murder Case while E O K Harwood, of Pretoria ows how circumstantial yet completely damning evidence s obtained in a case of murder by identification of a nture.

This journal will surely be welcomed by forensic patho ists, and possibly also by authors and readers of crime tion.

---

niversity of Cambridge

Dr Sven Moeschlin of the University Medical Clinic rich, will deliver a lecture on Friday Nov 20 at 4.30 P.M. the Department of Pathology Tennis Court Road He to speak on Immunological Aspects of Agranulocytosis.

On Oct 17 the degrees of M B., B CHIR. were conferred on O K Parsons.

niversity of Leeds

Dr Andrew Bogdan has been appointed senior registrar d tutor in pædiatrics ; and Dr I Bruce has been appointed urer in the department of anæsthetics.

ersity of Glasgow

T J Honeyman F.R.F.P.S., director of Glasgow Art lleries, has been elected rector of the university Dr neyman graduated M B at the university in 1916 and tised medicine until 1929

yal College of Physicians of London

Prof E J Wayne will deliver the Bradshaw lecture on rsday, Nov 12, at 5 P.M., at the college Pall Mall East ndon S W 1 He is to speak on the Diagnosis of Thyro icosis.

---

Royal College of Surgeons of Edinburgh

At a meeting of the college held on Oct 21 with Prof Walter Mercer the president in the chair the following were admitted to the fellowship

Festus Olaniyi Adewole Maqbool Ahmad Derk Crichton A B McL. Currie, Eli Davidowitz, K. R. Daymond, L. P Eaton, Fazal Elahi, J M. Foreman Toufic Elias Haddad Shaikh Abdul Hamid J M. Hastings Harry Koo Herman Klein Polavaram Lakshmipathy William Markkanen, Mithlesh Kumar Mehra, Nurgesh Darashaw Motashaw Hugh H Neifeld Kamal Mohamed Said Ganga Prasad Srivastava, N L. Stokoe, E. R. Treasure Mohsin Ali Vali G S Watson, J B R. Wells A. O Wilson C G Wilson, Abdullatif Ibrahim Yashruti.

Royal College of Physicians of Ireland

At the annual meeting of the college on Oct 19 Dr Edward T Freeman was elected president and Dr J A. Wallace vice-president

Royal Society of Medicine

On Oct 20 the gold medal of the society was presented to Sir Gordon Holmes F.R.S

Alfred Adler Medical Society

At a meeting at 8 P.M. on Thursday, Nov 12, at 11 Chandos Street London W 1 Dr T F Cotton will speak on the Psychological Element in Cardiac Disease

Research Defence Society

Sir James Learmonth will deliver the Stephen Paget lecture at a meeting of this society at University College, Gower Street London W C 1 on Thursday Nov 19 at 5.30 P.M. *He will speak on the Surgeon s Debt to Animal* Experiment

Institute of Dermatology

The institute is holding a series of semipermanent exhibitions during the winter course in conjunction with the department of medical illustration of the Hospital for Sick Children The second of the series is by Dr J A. Dudgeon on Virus Diseases of the Skin, and will be held from Nov 2 to 24

Royal Society

Mr Kenneth M Smith, F.R.S. will deliver the Leeuwenhoek lecture at the society Burlington House Piccadilly London W 1 on Thursday, Nov 5 He will speak on the Behaviour of Certain Viruses in their Hosts and of their Development in the Cell On Thursday Dec 10 Sir Francis Walshe, F R.S., will deliver the Ferrier lecture on the Contribution of Clinical Observation to Cerebral Physiology Both lectures are at 4 30 P M

College of General Practitioners

The first annual general meeting will be held on Saturday Nov 14, at 2 P M., in the great hall of B.M.A House, Tavistock Square, London W C 1 Foundation membership and asso ciateship will close on that day

The agenda for this meeting and the first annual report of the college were despatched to all members and associates on Oct 23 Any member or associate who has not received them is asked to communicate with the Secretary at 14 Black Friars Lane E C.4

Increased Number of School Dentists

There are now more dentists in the school dental service than there were before the introduction of the National Health Service in July 1948 Miss Florence Horsbrugh, the Minister of Education speaking at the annual dinner of the Society of Medical Officers of Health in London on Oct 22 said that by January 1948 the number of dentists in the school dental service had risen to the equivalent of 921 full time dentists but by January 1952, it had fallen again to 713. Today the figure was 928 This was an encouraging improvement but she wanted a larger school dental service and the Education Act 1953 had made clear to local education authorities their duty to provide such a service with comprehensive facilities for treatment

Leeds Old Students Dinner

The annual dinner of past and *present men students of the* School of Medicine of the University of Leeds will be held at the Hotel Metropole, Leeds, on Friday Nov 27 at 7 30 P.M when Sir Henry Cohen will be the guest of honour Tickets may be had from the hon secretary D A Youdale the Medical School Leeds, 2.

Royal Sanitary Institute

At a meeting of this institute to be held at Dudley Town Hall on Friday, Nov 27, at 10 15 A M, Dr Hugh Paul will speak on Infectious Disease—the New Look

Foot Health

This subject has been chosen for the annual seminar of the Central Council for Health Education for 1954 The seminar will be held at St John House, Collingham Gardens London, S W 5, from Feb 23 to 27 The programme will include a lecture by Mr T. T Stamm on Foot Function Further particulars may be had from the secretary of the council, Tavistock House, Tavistock Square, W C 1

Christian Medical Fellowship

At a meeting of this fellowship to be held at B.M A House, Tavistock Square, London, W C 1, on Monday, Nov 2, at 7 45 P M, Dr Robert Cochrane will open a discussion on Leprosy and its Challenge to Christianity

The fellowship is also holding a house party at Rustington Hotel, Sussex, from Nov 20 to 23 The main theme will be Is It My Concern ?—a Consideration of the Christian in Medical Practice The speakers will include Dr Margaret Edmunds, Mr Gerald Golden, Dr T S Goodwin, Dr J D Griffiths, Dr H Julyan Hoyte, and Dr W B Young Further particulars may be had from Mr L A H Snowball, Wakefield House, Compton Street, Eastbourne

The British Pharmacopœia 1953

On Wednesday, Nov 4 at 7 30 P.M, at the house of the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, London, W C 1, Mr T C Denston, PH C secretary of the British Pharmacopœia Commission, will give the first of a series of five lectures on the new *Pharmacopœia.* Other speakers will be Prof W H. Linnell, D.SC (Nov 12), Prof H Berry, F R I C (Nov 18), Prof A. D Macdonald, M.D (Dec 2), and Dr A A Miles, F R C P (Dec 10)

Commission on Divine Healing

The Archbishops of Canterbury and York have appointed a commission on divine healing[1] It will consider the theological, medical, psychological, and pastoral aspects of divine healing, and it will aim to provide a report which will guide the Church to a clearer understanding of the subject, which will help the clergy in the exercise of the ministry of healing and which will encourage increasing understanding and coöperation between them and the medical profession. The medical members of the commission are Dr J A Hadfield Dr Ronald Henson Dr Ronald Cove Smith, Prof. A Moncrieff, Sir James Paterson Ross, Dr Denis Brinton, and Dr David Stafford Clark Communications should be addressed to the secretary, Lambeth Palace, London, S.E.1

OBJECTIVE EXAMINATION PAPERS IN THE MEDICAL CURRICULUM

D C SINCLAIR
M.A. Oxfd M.D St And
UNIVERSITY DEMONSTRATOR IN HUMAN ANATOMY
UNIVERSITY OF OXFORD

MOST medical students regard examinations with most painful concern and indeed the influence which ey wield for good or ill renders them worthy of respect raminers however often make less effort than they ould to think critically about the too familiar weapons ey use, and in Britain medical examinations follow a irly stereotyped pattern It is therefore stimulating observe the objective type examinations of the edical schools of the United States, and to try to assess eir value in relation to the more conservative methods far used by British schools This article is not con rned with arguments as to whether or not examinations any type are desirable phenomena it merely accepts e situation that the vast majority of medical schools roughout the world employ them

The Traditional Examination Paper

FORMAT

In Britain written papers are usually three hours long d the student has to answer some five or six questions ; is usually allowed a restricted choice by the inclusion one more question than he needs to answer He has us a considerable time for each of the questions which so framed that he has to treat the subject at moderate igth. Questions are usually of the essay ' type roduced by the words ' Discuss,' Describe, ' " Give account of ' ' Compare and contrast," and the like, ly occasionally varied by ' Write short notes on,' or, rely ' Tabulate.

This format imposes fairly narrow specifications on h question : it must be capable of being answered in time provided yet must not be too short it must t be too difficult nor yet too easy it must be com tely unambiguous (the examination hall is full of sea yers) and it should be capable of connected and lerly treatment. It is a difficult task to frame a isfactory question meeting all these requirements ich has not, in one form or another been asked before. nce the frequency of old favourites, well tried questions ich have already served to distinguish the sheep from goats.

ASSESSMENT

For all professional examinations in Britain it is usual have at least two examiners and this arrangement tects the student against having his future decided on basis of one opinion only It can operate in this way ly if both examiners read all the scripts or if some er safeguard is adopted The assessment of (and netimes the mere physical act of reading) the average ay type of script is a time-consuming affair and it is en impracticable for both examiners to read every ipt. A common compromise is to mark by questions her than by candidates each examiner marking f the questions.

Many systems of assessment are in use (Vernon 1940) first sight it seems only necessary to establish whether candidate ought to pass or to fail but the paper ely forms the whole of the examination, and the essment of the script has to be made in conjunction h the oral and practical examinations. For this son a simple pass or fail system is not sufficient and e sort of scale is necessary so that the result can be en due weight

The most familiar method is to grade scripts in per centages drawing an arbitrary line at the pass level which is usually 50% Such scoring is a mere arithmetical convention a percentage of an abstraction. In medical subjects the examiner cannot sit down with a calculating machine and a list of all the possible points which could be made he records merely an impression having con stantly in mind the pass mark Nevertheless, so used are we in our daily life to handle figures which have been derived by legitimate mathematical means that he may be deluded into thinking he is performing an arithmetical operation, instead of using an arithmetical notation to record a fairly gross subjective judgment Just how much these subjective impressions and the marks which reflect them can vary has been shown by experiment with rather frightening results

For example Hartog et al (1936) obtained fifteen scripts which had all received the same moderate mark in a School Certificate examination in history, and circulated them to fifteen experienced examiners each of whom marked the scripts and placed the candidates in the category of ' fail ' pass,' or ' credit Over twelve months later the same scripts were resubmitted to the same examiners for the same procedure to be gone through On the first occasion the marks ranged from 21 to 70 out of 96, and on the second from 16 to 71 The difference between the highest and the lowest marks allotted to one of the candidates was 30 marks In 92 instances the examiners altered their original verdict of ' fail, ' pass, or " credit at the second time of examination and one examiner changed his mind about eight of the fifteen scripts he examined. In another part of the same investigation one candidate in School Certificate English was awarded marks varying from 28 to 80 out of 100 by seven different examiners.

Similar results have been obtained by other workers (Vernon 1940) and though no studies appear to have been made in medical subjects, there seems no reason to suppose that they would constitute an exception.

COMMENT

The essay type of examination is used to discriminate between students perhaps more often than any other educational test We should therefore ask ourselves what qualities and achievements it evaluates. This is not a simple question to answer but it is possible to make a rough list.

The essay type examination tests the ability of the candidate to comprehend simple written instructions at a moment of stress and, having done so to apportion his limited time judiciously It tests his factual recall and his power to select the most important relevant facts of which he is master It tests the speed and precision with which he can arrange and set down these facts in logical order and his capacity to develop with them a reasoned argument or a concise description It tests his ability to write spell, and punctuate his own language legibly and fast, his capacity to use and understand the language of science, his neatness and tidiness and finally the ingenuity with which he can conceal his own ignorance

Now many of these skills are undoubtedly desirable in a doctor as, indeed they are in any educated man

Intelligence is not listed among them since the results of essay type examinations do not correlate well with the scores obtained by candidates in tests which are commonly held to measure intelligence (Edholm and Gibson 1944 Bartlett 1953) It ought, perhaps, to be stressed that factual recall is only one among many achievements tested, and is placed in a wide setting concerned with the use of factual knowledge The way in which a candidate sets about answering a question is often just as big a factor in his success as the battery of facts he can unmask

On the other hand, the limited number of essay-type questions it is possible to ask in a single examination means that the sample taken of the student's knowledge will be small, unless the questions themselves are broad and comprehensive All examinees know that this is not always so, and questions which demand a detailed knowledge of a restricted field lead the student to cram his mind with detail to the detriment of his grasp of the broad outlines of the subject From this type of question also derives the time honoured practice of "spotting" questions, so that small sections of the subject are worked over to the exclusion of others because they are "bound to come up again this time"

The testing "in depth" of a limited part of the student's comprehension of the subject thus leads to an undesirable element of luck in the examination, and the student also feels that his future depends on an arbitrary selection of questions A single paper of six questions thus becomes a formidable psychological obstacle, causing students to work for the examination only, and not to attempt to acquire a grasp of the subject for its own sake For this reason it is often suggested that a second paper should always be given, to spread the load more evenly This argument is, however, capable of infinite extension, and the ground covered by two papers, though admittedly twice that covered by one, is still a small fraction of the whole subject

But the commonest objection to the essay-type paper is the extent to which the candidate is dependent on the examiner's purely subjective judgment Though discrepancies are smoothed out by compromise between the examiners, and also by the candidate's performance in the oral examination (if given), an uneasy feeling must remain that an educational test where such variability in assessment is possible is not wholly satisfactory

It is considerations of this kind, allied to the impracticability of marking vast numbers of essay-type scripts in a limited time, that have led to the introduction of the objective examination into medical subjects

The Objective Examination Paper

HISTORY

The objective examination has a history extending back some forty years, and is now a commonplace in American education up to, and often including, the college level In this country its influence has not yet extended much beyond the "eleven-plus" examinations The idea is that more of a subject can be covered by asking a large number of short questions rather than a few long ones, and that the questions can be put in a form that leaves marking independent of the examiner's subjective judgment It has been possible to eliminate altogether the human element in the marking process since 1937, when the International Business Machines Corporation developed a machine which would mark test papers electrically This has led to the widespread use of objective tests for many purposes throughout the United States, and some American universities now have a special objective examination service, which administers all university examinations

The introduction of this type of test to the medical curriculum is relatively recent, but in 1950–51 the National Board of Medical Examiners in the United States successfully converted their examinations in pharmacology and internal medicine to the objective format As a result, the Board is adopting similar measures for all the examinations under its control This step is being taken with the assistance of the Educational Testing Service, an organisation which specialises in the design, handling, and assessment of many similar tests, ranging from the United States Military Academy entrance examinations to the Medical Colleges Admission Test, which is now insisted upon by the majority of A medical schools (Stalnaker 1950) Such a move by the National Board, which is the only examining body recognised by virtually all the States in the Union, is bound to have a great influence on the type of internal examinations set in individual medical schools.

MULTIPLE CHOICE EXAMINATION

The National Board of Medical Examiners (195 publish a small booklet which gives examples of the ki of question the student may expect They are all of multiple choice type, in which the student is presen with a question and five possible answers, his duty merely to indicate his choice of the best of these answ There are usually 200–300 of these questions to answered in an examination lasting three hours but exact number varies with the subject The stud indicates his choice by blackening a labelled space in special answer sheet with a soft pencil, no writing involved

The questions are usually arranged in groups, group falling under a specific set of instructions. It not practicable to give examples of all types of ques but a few of the possibilities may suffice to indicate scope of the method as applied to medical subj they are all taken from the National Board's booklet

The simplest type is as follows

Directions—Each of the following questions or incom statements is followed by five suggested answers or pletions Select the one which is best in each case and bl the corresponding space on the answer sheet

Q In airborne first-infection tuberculosis the prim focus is most commonly found in the

(A) periphery of the lung
(B) tonsil
(C) apex of the lung
(D) tracheobronchial lymph nodes
(E) hilus of the lung

There are many variants of this

Directions—Each group of questions below consists of lettered headings followed by a list of numbered words phrases For each numbered word or phrase select the heading which is most closely related to it and blacken corresponding space on the answer sheet

(A) Quinidine
(B) Theophylline
(C) Amyl nitrite
(D) Glyceryl trinitrate
(E) Papaverine

Q Increases the contractile force of the heart and diuretic

Another type of question requires quanti information

Directions—The following paired statements describe entities which are to be compared in a quantitative On the answer sheet blacken the space under

A if (A) is *greater than* (B)
B if (B) is *greater than* (A)
C if the two are *equal or very nearly equal*

Q (A) The amount of glycogen in the cells of Henle's in a diabetic

(B) The amount of glycogen in the cells of Henle's in a non diabetic

The directions may be quite complicated

Directions—Each of the following pairs of phrases desc conditions or quantities which may or may not be On the answer sheet blacken the space under

A if increase in the first is accompanied by increase in second or if decrease in the first is accompanied by de in the second,

B if increase in the first is accompanied by decrease in second or if decrease in the first is accompanied by inc in the second,

C if the second remains constant, or approx constant, when the first increases or decreases.

Q 1 Cerebrospinal fluid pressure 2 Intra-ocular p

In the preceding group of questions only possibilities are presented to the candidate, but in a similar group there are five

Directions—Each of the following sentences consists of two ain parts; a statement and a reason for that statement. n the answer sheet blacken the space under

A if the statement and the proposed reason are *both true* and are *related* as cause and effect;

B if the statement and the proposed reason are *both true* but are *not related* as cause and effect;

C if the statement is *true* but the proposed reason is *false*;

D if the statement is *false* but the proposed reason is *an accepted fact or principle*;

E if the statement and the proposed reason are *both false*

Q The corpus luteum of menstruation becomes the corpus iteum of pregnancy because progesterone inhibits the activity f the anterior portion of the pituitary gland

Another group of questions consists of several case-istories, each followed by a series of questions each with ve possible answers these questions deal with such atters as the most likely diagnosis, the most likely dditional physical finding the probable outcome of the isease if left untreated, and so on

Setting the questions is a laborious task, for on their xact form a great deal depends. The procedure in tting the National Board examinations is outlined by ie Educational Testing Service in their booklet *Building Test* (1953) The questions in a particular subject are cided at a meeting of the examiners and cast into a itable form with the help of a member of the testing rvice. After checking the questions are experimentally dministered to a group of students, usually by including iem as unscored items in another test on the same ibject The answer sheets relating to these items are en subjected to a process known as 'item analysis,' hich shows how many students selected the 'keyed' correct answer and how many selected each of the decoys A good question is one which good students s evaluated by their score on the whole test) will answer rrectly more often than mediocre or poor students and is possible to give mathematical expression to the pacity of the question to discriminate between good id bad students.

The results of item analysis often lead to recasting the question For example, if it is found that good idents tend to prefer one of the 'decoys' instead of e 'keyed' answer, the wording is immediately spect. Indeed, the wording is often extremely impor nt. If one of the decoys is several words longer than e others, this in itself will attract more preferences from or students. Two of the decoys may overlap so that one were correct the other would have to be also or nversely they may be self-exclusive so that if one is rrect one or more of the others cannot be Pure logic ay thus lead a candidate to the correct answer (Vernon nd Davis 1950)

The questions on trial are also rated for difficulty the n being to provide in the final assembly of questions a ge from items that are easy to those which are tremely difficult so that the average student will swer slightly more than half the items correctly (In is type of examination the pass mark is just as arbitrary in essay questions; the students are ranked in order their prowess in the examination and a subjective cision has then to be taken as to where the failure-line st be drawn) The speed with which the questions n be answered is also taken into account and adjust nts are made so that 80–90% of an average class have ne to attempt all the questions in the final assembly hen the test is put together it is again checked, and ven to another batch of students for final trial

All questions are regularly reviewed by the committee examiners, and so kept up to date in the light of reasing knowledge Medical questions are perhaps ticularly difficult to frame for as the National Board Medical Examiners point out:

> in the broad field of medicine contrast may not be rply defined as between black and white but rather varying shades of grey In answering these questions, therefore, one should look for the best choice, and not be misled by other choices which might be considered possible but still less applicable than the one considered correct In each case the test committee has agreed that there is only one best answer

It is often hard to find a sufficient number of decoys which will really decoy If one or more of them is too obviously unacceptable, the choice is no longer between five answers, but between a smaller number with a correspondingly greater random chance of hitting the correct one.

The process of setting an objective type examination containing perhaps 200 questions is thus not to be undertaken lightly and expert advice is not available in every medical school Many amateurs may find hard wrought questions ruined by the curse of unsuspected ambiguity which sits on the shoulders of everyone who has put inquisitorial pen to paper Nevertheless these examiners reap their reward when the time comes for assessing the answer sheet.

Under the objective system the booklet containing the questions is handed in again at the end of the examination and can be used a second time at some future date It is possible in this way to accumulate a stock of questions of such magnitude that after the initial labour the examiner will never need to set any more but will simply draw a fresh combination of questions from his stock. His duties as an examiner would then reduce to servicing his questions and assessing the results, which if a machine is available is almost an automatic process The general opinion is that a stock of some 5000 questions in a given subject would ensure an examiner a life of ease and comfort, but the student fraternities are attempting to circumvent such proposals by industriously setting their members the duty of memorising two or three questions each and writing them down after the examination for future study Most examiners however feel that it is more difficult for a student to memorise the answers to 5000 questions than it is for him to learn the subject

ASSESSMENT OF MULTIPLE CHOICE EXAMINATIONS

If the tests are hand scored the rate of correction may be up to 50 answer-sheets an hour If electrical marking is used the answer-sheet is inserted in a special machine in which a large number of electrical contacts are masked by a master stencil with holes cut in it corresponding to the position of the correct answers in the test being marked. The pencil marks allow a current to flow through the contacts and the machine counts the number of correct and incorrect answers by measuring the amount of current flowing The score may be read off directly from a meter, and the machine will also register percentages part-scores, right answers minus wrong answers (or any desired fraction of wrong answers) and so on at will. The operator has thus merely to insert the sheets and write down the scores, so that it is possible to score 700–800 tests an hour I understand that a further development of the machine is proposed in which the mark obtained will automatically be printed on the answer-sheet It is a sad commentary on human frailty that it is often necessary to go over the answer sheets before scoring to ensure that the pencil marks are adequately black.

Machines enable an immense amount of data to be analysed quickly and since the scoring is truly arithmetical, statistical comparisons are valid It is possible to compare directly the performance of two groups of students or the performance of the same group on different sections of the test Thus, if the students of a particular medical school equal or surpass the mean performance of those in all other medical schools in every subject but one it is pertinent for the school to inquire into the teaching of that subject. It is also interesting that on at least one occasion an analysis of the machine-marked results has revealed a leakage of information about the content of the examination (Cowles 1953)

OTHER TYPES OF OBJECTIVE QUESTION

Though the multiple choice question is generally regarded as the most useful and reliable, many other objective questions are in use

(*a*) *True or false* —This is the simplest form of multiple choice, and has similar advantages and defects, but the element of chance is greater An example from a recent histology paper reads

Directions —Encircle the appropriate letter to indicate each statement as either true or false

Q T F Blood vascular channels are present within lymph-nodes

(*b*) *Matching* —The candidate has to match a set of items with their attributes This is sometimes done in tabular form—e g ,

Directions —Indicate which of the cells or tissue elements listed below are normal components of the organs which head each of the following columns Place an X mark in the appropriate square

(There follows a list of ten tissue elements ranged down one side of a square along the top of which are arranged ten organs)

(*c*) *One-word and "fill-in"*—These have to be answered by one word or one phrase only—e g ,

Q In what organ is the sequence arteriole–capillary–sinusoid–venule found ?

Fill-in questions may leave several blank spaces in a sentence

Q The presence of.............. ....and..................tissue in the tunica..................of arteries enables them to accommodate fluctuations in blood pressure and volume, while the presence of ....in the tunica..................prevents over distension.

(*d*) *Various* —Considerable enterprise is being used in framing new variants of the objective pattern Duplicated diagrams or drawings are left with the leaders unlabelled, and the student has to fill them in , he may have to complete tables showing the contrast between two diseases or drugs, to recognise structural chemical formulæ, to give a one-word diagnosis or a one-word treatment on the basis of brief case-histories, and so on The department of psychiatry at Johns Hopkins use a test in which eight brief biographical sketches are separated into two parts (1) the later career , and (2) the early life and family background The student has to fit them together

COMMENT

The objective paper clearly allows a more extensive sample to be taken of the student's knowledge, though the sample in different areas may penetrate to varying depths beneath the surface In comparison with the essay-type examination, the skills tested are not so numerous Chief among them are the ability to comprehend written instructions and the power of discrimination, the ability to reason from cause to effect is also tested in certain questions Almost of necessity, the questions aim at the uncovering of factual knowledge, but the power of factual recall is not so heavily drawn upon as in the essay question In multiple choice questions, the student has at least the advantage of knowing that the fact he is required to remember is in front of his nose, if he can but chip it out from its matrix of irrelevancies The element of guesswork is constantly present (Ruch 1929), and the student who answers completely at random will score marks through ignorance (For this reason it is common to weight the marks in such a way that wrong answers are taken into account as well as right ones) There is no opportunity for originality in the answer, and the student cannot be asked his views on any debatable point The candidate's powers of self-
n and his ability to expound a logical argument or a methodical description are not tested, nor is his
in spelling and writing his own language grammatic

The form of the multiple choice question is
to the form of certain questions asked in intellige
tests, and it might be expected that "intelligence" wo
be considerably involved in objective examinations
this sort, though direct evidence of this for me
students does not seem to be available

Subjectivity has by no means been eliminated
objective type examinations , it has merely been tr
ferred from the marking of the questions to the se
of the questions Individual examiners may set ques
of widely differing standard, and have their own view
the best answer Thus Pullias (1937) found a relati
low correlation between the marks of the same stud
in objective examinations designed to cover the
subject but set by different examiners This obje
is, however, largely met by having the questions
by a large committee of examiners

Again, the determination of success or failure is
an arbitrary decision The failure level must be de
mined after the marks are known and not before, and
thus related to the mean performance of the whole
and not to any absolute value This is known as "
on the curve," and in effect converts the exam
into a competitive one

Cowles and Hubbard (1952) obtained evidence
favour of the multiple choice examination during
trial change over of the National Board of M
Examiners' examinations in pharmacology and in
medicine In each subject, two hours were give
essay type questions and one and a half hours to mu
choice questions The medical schools furnished
fidential reports stating which students in their op
were in the top 20% of the class and which were in
bottom 20% It was found that in both subjects
correlation of objective test scores and medical
ratings was significantly higher than the correlat
essay scores and school ratings, and Cowles and Hu
consider that

> "(1) the objective examination, when carefully
> diligently prepared, appears to offer more reliable and
> evaluation of the student's knowledge and his ability to
> that knowledge to the situation in hand than can be o
> from the time honoured essay examination , (2) the ob
> examination lends itself to thorough statistical analys
> that it may be accurately and intensively assessed, leadi
> recurrent revisions permitting steady improvement of
> examinations "

Nevertheless, many people, both in the United
and elsewhere, watch the advance of the ob
examination with concern, because they feel that
examinations test only a limited number of the qu
which are needed by a doctor Already in some Am
medical schools there are students who have never
exposed to any other form of examination thro
their whole educational career It is felt that
students should at least have the opportunity of
ing their opinions on paper Many schools, th
while including multiple choice questions in their in
examinations, continue to ask other types of questi
well In some instances these are full blown
questions of the traditional type, but in other
attempt has been made to avoid some of the draw
of the essay question, usually by means of short-a
questions

Short-answer Questions

Here a restricted space is provided for the stu
views, and he has to achieve a compression of his
which must therefore be stripped of the unn
verbiage so common in essay-type answers (Dobbie
Barnes 1950) The key-words in such questions
"Define," "Outline," "Name," and so on—e g ,

Q Define adequately in one well constructed sentence any ur of the following : (limit $1^1/_2$ pages)

1 sarcoplasm
2 reticulum
3 serosa
4. parenchyma
5 arteriole

Q Outline under well planned headings and subheadings otal of 20–25) a discussion of ‘ The human skin and its erivatives.

uch questions test the student's grasp of essentials and npose little strain on the examiner they may, in fact e termed ‘ semi objective.”

General Discussion

All medical examinations basically seek to establish hether the student has a command of the subject dequate for him to be considered fit to undertake the ractice of medicine, either immediately or at a later date Roberts 1946) It is in this sense of an achievement est that examinations are usually regarded. Yet they ave a value as a teaching medium for students if the aper is discussed with the class after it is over and ome schools give out model answers for this purpose hey can also teach those teachers who take the trouble find out from the results which parts of the subject ave not penetrated their students' understanding ernon 1940)

The essay type examination is still the standard strument for distinguishing between good and bad udents Such papers are the means by which success failure are often determined scholarships won and mours awarded. They have on the whole, worked uitably in the past, and may continue to do so in the ture. Yet some people have the knack of answering say questions, and others though equally capable udents, have not Some schools have tried allowing the udent to bring into the examination room any books e wishes this does not result in a significant improvement of the standard, and occasionally upsets the udents. At least two American departments pro eding on the theory that a student ought to know st what he knows, have tried allowing each student set himself a question and then answer it the sults were catastrophic and the experiments were not peated.

There is in fact a definite technique of answering say type questions a technique which comes naturally some people but has to be painfully acquired by others, ho may fail simply through lack of experience in it obody would pretend that justice is always done, and y modification of format or procedure which may sult in fewer injustices is worth consideration. Examina ons are not the only means by which the worth of a udent may be assessed and it is highly desirable that e should have a clear idea of what we are doing when we t and mark a written paper It is one of the benefits the introduction of the objective examination into edical affairs that it will force us to think again about e form in which our own papers are set

At present we must regard the medical objective amination as something which has still to prove its orth despite the interesting studies which are being dertaken on its relation to student proficiency But ere is little doubt in my mind that a generation of octors brought up on objective examinations will be fferent from the generation brought up on essay type estions, for the form of the examination not only tests e student, but also colours the way he works (Vernon 40). Whether they will be better or worse doctors is a estion nobody is likely to be able to answer for at least any years to come and one is tempted to say that ychology is gaining a measure of control over medical ucation through the weapon of achievement tests much in advance of its ability to evaluate the changes which it is introducing Nevertheless these changes are of the greatest interest, and deserve the closest consideration from every medical examiner As Vernon (1940) points out, neither type of examination can be considered satisfactory by an impartial observer but their faults to a certain extent cancel out It is perhaps to a combination of objective and essay questions in the same paper that we must look for future advances in the science of examining

I made these observations during a trip to the United States under the auspices of the Rockefeller Foundation, whose help I gratefully acknowledge I should also like to thank the National Board of Medical Examiners for permission to quote from their examination questions, the department of anatomy at the University of Rochester for the use of some of their questions, and Dr John T Cowles of the Educational Testing Service for his invaluable and patient assistance

RESUSCITATION OF THE NEWBORN WITH INTRAGASTRIC OXYGEN

(AKERREN'S METHOD)

HAROLD K. WALLER
M.B Camb., F.R C.O G

DAVID MORRIS
M.R.C.P ; D C.H

PÆDIATRICIANS BRITISH HOSPITAL FOR MOTHERS AND BABIES WOOLWICH LONDON

IN contrast with the general decrease in infant mortality during the past fifty years the stillbirth rate and the neonatal death rate have remained obstinately resistant to improvement. Thus Smith (1951a) has reported that of every 10 000 births in the U.S.A some 150 lives are lost in stillbirth and a further 150 infants fail to climb out of what he has called the Valley of the Shadow of Birth.' In this country deaths in the first day of life still account for 38% of those occurring in the first month of life (the neonatal period)

One important cause of these deaths is asphyxia *neonatorum* Moreover of those who survive this dangerous complication not all escape damage to the central nervous system.

The establishment of respiration in the asphyxiated newborn infant is as much a problem today as ever Whatever primarily causes depression of the respiratory centres and prevents them from acting the delay or insufficiency of respiration itself deepens the anoxia with still further depression of the respiratory centres. The primary purpose of treatment is to prevent this additional secondary anoxia. Of the many different methods advocated and practised to combat asphyxia neonatorum no single one has received universal approval. Methods once popular have fallen into disfavour and others have been abandoned because they were found harmful The present tendency is toward gentle rather than vigorous stimulation, but, on the other hand, the apparatus and procedure devised for producing this stimulation have tended to become increasingly complex What is much needed is a method which is simple, safe, and effective, and ideally could be used in home confinements

One with claims to fulfil these criteria was reported by Akerren and Fürstenberg (1950), who described the resuscitation of asphyxiated newborn infants by passing oxygen into the stomach Ylppö (1935) had already shown that in premature infants oxygen in the alimentary tract is absorbed directly into the blood stream from the capillaries of the intestinal mucosa

We have been unable to find any account of the use of this method since the publication of Akerren's original article In this paper its use in 48 infants is reported

Method

It is the nurses in the labour ward who are confronted with the asphyxiated baby, and we have found it perfectly safe to entrust them with the decision to use Akerren's method Time is thus saved, and time is the important factor Normally, when the head is born, the inside of the mouth is wiped carefully with a square of soft linen, and mucus is aspirated from the pharynx with a mucus extractor As soon as the infant is born, the cord is tied and cut, and the infant is placed in a warm cot with a small pillow humped into the loins and with the head slightly lower than the feet, aspiration of mucus is then repeated if necessary By this time most infants will be breathing well If respiration is delayed, the tongue is firmly gripped with small pointed tongue forceps at least $^{1}/_{2}$ in from its tip, and gentle traction is applied If despite this the infant does not breathe or gives no more than an occasional gasp, and especially when the heart beat by becoming slower and feebler indicates that the infant's condition is deteriorating, then Akerren's method of resuscitation is applied If the infant is born white and shocked and shows no sign of immediate improvement, the method is used without delay It has taken the place of stimulants such as nikethamide and lobeline

In each labour ward is kept an autoclaved box containing four Jacques catheters, a pair each of sizes 5 and 3, one catheter of each pair serves as the inlet and has a glass connection for attachment to the pressure tubing of an oxygen cylinder The second of each pair serves as a safety or outlet catheter The pair appropriate for the size of the infant is chosen, and the safety catheter is passed first The stomach contents are aspirated, the nurses being satisfied that the response is better when this is done The upper end of this catheter is then placed under water in a small gallipot The inlet tube with the oxygen running through it is passed, and within a few moments the stream of bubbles in the gallipot shows that oxygen is entering and safely leaving the stomach The catheters are left in situ until spontaneous breathing is well established The abdomen is watched, and, as the oxygen enters, the stomach and sometimes the intestines may be seen to bulge With the oxygen running at 1 litre a minute, the abdomen was not unduly distended in any of the children in our series

First Trial

The first occasion when we used this method seems to us to merit a special description In 1949 Dr Akerren visited our hospital, and, just before leaving, mentioned his method modestly, indeed almost casually, to one of us (H K W) No trial was made of it for many months The notion of inflating the stomach of a severely shocked baby was startling Responsibility for making the first experiment could hardly be delegated to a resident, certainly not to a nurse, and the likelihood of being in the hospital at just the right moment for trying it was remote The project seemed impracticable as well involving risk It was allowed to pass out of mind

"The mind," wrote Wilfred Trotter (1941), "likes a idea as little as the body likes a strange protein, and it with a similar energy It would perhaps not be too f to say that a new idea is the most quickly acting known to Science"

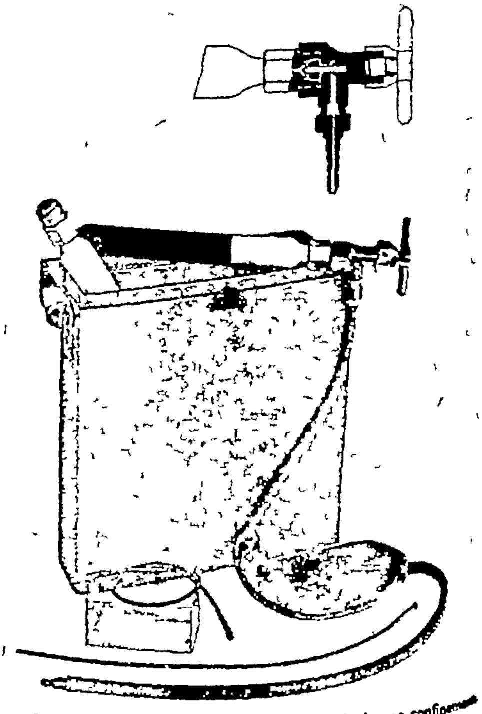
Even when the opportunity arose, this instinctive r tion, so comfortably rationalised, still delayed trial o method until its chance of success had become unfavourable as possible It is chastening to reflect had it failed on that occasion, we should have been than ever tempted to reject it finally So much by of apology to its originator The occasion of its trial as follows

A primigravida, aged 31, was delivered by Mr C K V after a labour lasting thirty hours Under open ether breech extraction was done by Lovesett's method, and were applied to the aftercoming head The infant was white and toneless The air passages were cleared, the was tied, and oxygen was directed through a tube into mouth at 4 litres a minute after the tongue had been forward The heart was beating at 70 a minute The gasp occurred after 5 minutes, and then at intervals of 40, and 30 seconds, giving hope that breathing was However, for half an hour there were only gasps weakened, became less frequent, and finally became imperceptible After 65 minutes the heart was irregularly at 35–40 a minute, and its sounds were only audible

It was at this point that Akerren's method came to Catheters and connections were quickly assembled, oxygen was passed into the stomach, whose distended was immediately seen through the lax abdominal wall minutes later (75 minutes after birth) the infant became pink, and full regular respirations were established with dramatic rapidity Thereafter the baby gave no cause further anxiety and when last seen at 3 years of age appeared to be developing normally

Experience of 47 Other Cases

After this favourable experience we decided to use method whenever severe asphyxia did not respond the routine procedures described In the



Apparatus for the resuscitation of the newborn in home confinem ries of 48 infants so treated 7 did not respond 41 re resuscitated, but 3 subsequently died (at $1^{3}/_{4}$ hours hours, and $2^{1}/_{2}$ days) In those that responded the ual sequence of events was a change in the infant's lour to pink, followed by the onset of breathing at a riable time In our series this ranged from 1 to 75 nutes. The accompanying table shows that most of e infants were breathing within five minutes though 2 ok as long as an hour

nutes before breathing ygen	1	2	3	4	5	10	15	15+
mber of infants	14	6	7	0	3	3	3	6

At necropsy severe cerebral damage was found in 3 bies and in the remaining 7 the only findings were lectasis and evidence of asphyxia.

Apparatus for Home Confinements

As oxygen is usually available only in hospitals the actice of this method is at present restricted. Accord ly we have devised a miniature portable cylinder* e figure) which could be included in the general practi ner's or the midwife's equipment It is supplied in an dily portable box containing two miniature cylinders screw tap, rubber tubing a pressure bag and two ques catheters; the box and contents weigh 5 lb e tap is screwed on to the cylinder and the handle is ned in a clockwise direction; this drives a piercer the cap whereupon oxygen fills the bag and then s out at 1 litre a minute There is enough oxygen in h cylinder to give a continuous supply for 20 minutes. s equipment will we hope, enable the doctor or the wife to apply this method of resuscitation in the home

Discussion

n spite of the large amount of experimental work way in which respiration is initiated in the newborn ant is still not clearly understood. Moderate anoxia sensory stimuli are the main factors (Smith 1951b) for any reason respiration is not established, the tinued anoxia leads not to stimulus but inevitably greater depression of the respiratory centres, with less likelihood of the establishment of breathing aim of treatment, therefore is to prevent this ression by supplying oxygen, although this cannot course directly affect the primary cause of failure he respiratory centres to function The delivery of gen to the respiratory centres has been the aim of y different resuscitative measures That it is rapidly orbed from the gastro intestinal tract has been clusively demonstrated, but what makes the respira centres respond in one child and not in another ains a problem, as is illustrated by the cases when, pite of our endeavours, no cause for failure to respond d be found either clinically or at necropsy No roscopic examination was made for the presence of line membrane

may be objected that the claim made here for this hod could be established only by a controlled study once it was found to be clinically effective, it became ssible to withhold it from any infant who might be efited. In our experience Akerren's method is simple and effective We have also used it successfully ral times for the treatment of severe cyanotic attacks in nature infants as originally practised by Ylppö (1935) he miniature light weight oxygen container described enable this method of resuscitation to be practised only in hospitals, as at present, but also in domiciliary wifery

THE title of this paper, though not strictly accurate, is reasonably apposite. Actually this is a study of cases in which pregnancy was prolonged past the expected date of confinement calculated by Naegele's rule.

In the present state of knowledge it is impossible to make an exact clinical study of postmaturity owing to the lack of any clear definition and to the difficulties in diagnosis Possibly because of these difficulties, and because postmaturity and prolongation of pregnancy are often accepted as synonymous there is a wide variation of views on the importance of this subject. Kamperman (1948) says that postmaturity is a state of mind of the obstetrician in most clinics the problem is not considered important enough to deserve much study and Holmes (1948) says that "Postmaturity is a figment of the imagination On the other hand many workers hold that postmaturity is important.

It might be supposed that the problem could easily be solved by simple pragmatic methods, such as the study of fœtal mortality figures. The obvious difficulties to this are the lack of exact definition of postmaturity and the obscurity of diagnosis It is for this reason that we have investigated postmaturity in relation to the expected date of confinement estimated from the last menstrual period by Naegele's rule. We fully realise that this method is not free from error as regards postmaturity This study however, is concerned not with postmaturity in its exact sense but as to whether it matters if a woman has her confinement at the expected date or later We believe that in women who are reasonably certain of the date of their last menstrual period, and after a correction has been made for a menstrual cycle longer than twenty-eight days, this rule is still the most useful guide in the management of these cases. It has the additional advantage of requiring no exceptional skill or any special methods and can therefore be used by practitioners everywhere.

We are aware that this scheme of management is open to the criticism that each case is not treated individually But individual treatment, avoiding routine induction is a counsel of perfection, and, though it may become possible in the future, is not applicable in the present state of knowledge In fact, slavish adherence to individual treatment is a cause of the high fœtal mortality in postmaturity

A few workers (Clayton 1941 McKiddie 1949 Hamilton 1950, Latto 1951 Rathbun 1943) have published reports on the fœtal mortality in pregnancies prolonged past the expected date of confinement, and almost without exception they show an increase in the fœtal mortality Latto (1951) and Rathbun (1943) by excluding certain cases seek to show that the increase is not in fact substantial but they offer no conclusive evidence to justify the exclusion of these cases. As corrected figures are always debatable we have made no correction in our study and we hope that if others can be interested to carry out similar investigations, it will be possible to gather series large enough to make correction unnecessary

Method

In our investigation at Park Hospital we divided the patients attending our antenatal clinic into two groups by nothing more eclectic than which clinic they attended—either that of one of us (D C R) or of one of his colleagues who kindly allowed his cases to be used for this study In one group, called the induced group, the patients were admitted on the day before the expected date of confinement, on which day they were given such simple stimulants as a hot bath and an enema, but no drugs, and, if labour had not started on the next day, the membranes were artificially ruptured There was absolutely no obstetrical selection in either group For example, in the induced group labour was induced whether the women were primigravidæ or multiparæ, whether the head was engaged or high and mobile, and even if there was a breech presentation In a few of the earlier cases the patients were given 'Pituitrin' on the expected date of confinement, but this practice was discontinued for the reason discussed below

TABLE I—FŒTAL MORTALITY DUE TO STILLBIRTHS

Group	No of cases	No of stillbirths
Controls (mature at term)	1229	19 (*1 54%*)
Induced group	203	3 (*1 47%*)
Postmature group	410	19 (*4 63%*)

In the second group, called the postmature group, the women were allowed to continue to spontaneous labour unless, as happened in a few cases, labour was induced for some other obstetric reason

A third group of cases acted as controls, these were the unselected cases of natural delivery at term in the past two years—term for this purpose being from seven days before to seven days after the expected date of confinement

As regards the induced cases we do not suggest that the results could not be equalled or even possibly improved by allowing an interval of seven to ten days to elapse after the expected date of confinement, as suggested by Mills (1950) To find this safe margin further study is required We chose the day after the expected date of confinement to induce labour because we felt that some starting-point was needed, and because, if our results were reasonable, it would provide a ready answer to those who might argue that we would have a high proportion of premature babies

Results

Table I shows the fœtal mortality due to stillbirths The postmature cases in this table were more than seven days past the expected date of confinement They outnumber the induced group simply because the resident staff, who see a large number of the cases, often did not arrange for their admission on the correct date, the routine being new to them

TABLE II—STILLBIRTH RATES IN POSTMATURE CASES

Postmaturity	No of cases	Stillbirths
From 7 to 13 days	261	6 (*2 31%*)
14 days or more	149	13 (*8 72%*)

Table II shows the difference in stillbirth rates between postmature cases up to fourteen days past the expected date of confinement and those more than fourteen days past it The differences between the fœtal mortality-rates of the postmature groups and between the induced group and the group in which the postmaturity was more than 14 days are statistically significant Table III shows the degree of agreement between our figures for stillbirth-ra [illegible]d those published by other workers Table IV gives the incidence of postmaturity both in our own c and in those published by other workers

TABLE III—COMPARISON OF STILLBIRTH RATES

Authority	No of post mature cases	Stillbirth rate		Criteria of post maturity
		Mature cases	Post-mature cases	
Hamilton (1950)	171		8 2	291 days
Latto (1951)	171		5 2	294 days
McKiddie (1949)		1 3	2 8	287 days
Clayton (1941)		4 25	6 15	291 days
Present investigation	410	1·54	4·63	287 days
" "	149	1 54	8 72	294 days

There was 1 cæsarean section in the induced and 8 in the postmature group The instrum rate in the induced group was less than half that in postmature group This is in agreement with Clay (1941), McKiddie (1949), Hamilton (1950), Latto (195 and Rathbun (1943) In the postmature group were 3 deaths in utero before the onset of labour

In the induced group containing 203 cases it necessary to rupture the membranes in 162 cases. T interval from the time the membranes were rupt until delivery was as follows less than twenty-f hours 61 cases, from twenty four to forty-eight h 70 cases, and more than forty-eight hours 31 c The interval between the rupture of the memb and the onset of labour, judged by the start of re pains, was more than forty eight hours in 10 ca two to five days in 5 cases, six days in 3 cases, seven days in 2 cases One of us (D C R) was through illness for a long time when these cases occ and owing to a misunderstanding no uterine-stim drugs were used, if they had been used, several of long intervals might have been avoided One o 3 fœtal deaths took place in a case in which the memb were ruptured for a hundred and fifty hours b delivery In 16 cases labour lasted more than hours The smallest baby in the induced group w 5 4 lb The average birth weight was almost e equal to that of the controls

TABLE IV—INCIDENCE OF POSTMATURITY

Authority	Incidence %	
	Criterion 287 days	Criter 291 da
Gibson and McKeown (1950)	31 72	
McKiddie (1949)	24 10	7 3
Clayton (1941)		3 (
Latto (1951)	25 20	9 (
Present investigation		

As will be seen from the combined figures tables, the fœtal mortality for cases fourteen d more overdue is about 7% If the incidence of cases is also about 7%, on an annual birth rate of 8 the fœtal mortality is about 3920 per annum fœtal mortality for the induced cases can be by further work to correspond to our figure of le 2%, the yearly fœtal salvage would be about 3 annum, a rather startling figure

Discussion

Our reasons for making this investigation were felt that the question of postmaturity needed cl and we wished to assemble evidence on which to management of these cases Our argument follows

(1) It is impossible at present to diagnose post either clinically or radiologically with anything a ing sufficient accuracy upon which to base any tr

(2) It follows that it is impossible to treat all the cases dividually What is really necessary before cases can e treated individually is an accurate method of detecting rly and minor degrees of deterioration of the fœtal ondition in utero

(3) There is strong theoretical evidence that the etal environment deteriorates after term That some etal deaths after term are due to malpresentations or to ng and difficult labour rather than to intra uterine ysiological changes alone, or to a combination of these o factors does not in any way affect the main issue.

(4) Therefore labour should be induced at or after a rtain interval following the expected date of confinement. We believe that a certain degree of prematurity preferable to the same degree of postmaturity The terval that can safely be allowed after the expected ate of confinement is a matter for further investigations. rom our present knowledge we feel that it will probably ove to be about seven to ten days

Not one of the criteria commonly used in the diagnosis maturity can definitely foretell when it has been ached Even if they are all used, the margin of error a few days therefore they cannot be used as a certain ride to treatment These criteria are

(1) The calculation of the expected date of confinement the Naegele rule This has already been discussed
(2) Estimation from a single coitus
(3) The growth of the uterus.
(4) The date of quickening
(5) The size of the foetus
(6) The feel of the fœtal skull on combined abdominal d vaginal examination
(7) Rigidity of the foetus
(8) Oligohydramnios.
(9) The condition of the cervix
(10) Radiology
(11) A test induction with pituitrin.

Rigidity of the fœtus due to increased tone in the eletal muscles, and oligohydramnios have been phasised by Wrigley (1046) as important signs t can anyone really assess the tone of the fœtal scles or a decrease of liquor accurately enough to stify embarking on a certain course of treatment of such portance ? We have specially looked for these signs, d although we agree with Wrigley that oligohydramnios y at times be marked, its occurrence is irregular and th signs are usually too esoteric to have any value as a ide to treatment.

As regards *radiology* there are still no signs either centres of ossification or in skeletal configuration ich can be used as accurate criteria of postmaturity

Some workers state that *pituitrin* and *pilocin* are y effective when the foetus is mature, and can therefore used to test maturity We have no real information this subject ; but, apart from a few early cases in present series we have not used pituitrin as part of a ical induction We have, of course, used it in the t, but we felt that it would not help us in the present estigation, owing to doubt about its action. In es in which it is given and has no effect one cannot certain that the reason for this is that they are not term, until it can be shown that pituitrin always mulates the uterus at term in every case

We therefore feel that, apart from the cases where ere is an obvious discrepancy between the signs and mptoms and the expected date of confinement, these ns and symptoms of postmaturity have not the ue that some impute to them We agree that when eral of these signs are present together one can ten presume postmaturity with reasonable confidence t they still tell us very little about the health of the tus and in the many cases in which they are absent are virtually helpless unless we have a scheme of nagement such as the one we propose We only gest such a scheme until more accurate diagnosis out the fœtal condition renders it unnecessary

We shall not discuss in detail all the physiological factors which may endanger the life of the fœtus in utero It is now fairly generally agreed that the fœtal environment deteriorates after term to illustrate this deterioration we cite (under the heading of Bibliography) a few of the many recent publications on fœtal asphyxia Of the many factors involved—e g the fœtal and maternal circulation the efficiency of the placenta and placental reserve and the transference of metabolites and electrolytes—the factor which is most easily understood and which appears to be most important is fœtal asphyxia A great deal of work has been done on this subject tending to show that the oxygen content and saturation of the fœtal blood decrease after term

Walker (1053) found that at the 30th week of pregnancy the average oxygen content in the umbilical vein was at least 14 vols. % with a saturation of 70% The arterial content and saturation were roughly half the venous. At the 39th week the oxygen content was reduced to 12·4 vols. %, giving a saturation of 60%. At 42 and 43 weeks the venous oxygen content was, on the average as low as 6–9 vols %, the saturation being 30–40% An important finding of Walker's was that throughout pregnancy the difference in oxygen content between fœtal arterial and venous blood remained very constant at about 5–7 vols. %.

From Walker's work it is evident that if the venous content diminishes to 6–0 vols % as it often does after term, the arterial oxygen content will be so low that the life of the fœtus is in jeopardy Thus must lead to especial danger if the labour is in any way difficult or prolonged. We are not in a position to comment on the importance of this theoretical hazard but there is little doubt from a practical standpoint that the fœtal mortality is increased after the expected date of confinement (Clayton 1941, McKiddie 1949, Hamilton 1950 Latto 1951 Rathbun 1043)

If these hypotheses are accepted it follows that it is safer in the present state of our knowledge to treat cases according to some rule rather than individually We realise that this is unsatisfactory but feel that it is much safer until such time as we can judge the condition of the fœtus in utero In cases which appear quite normal the fœtal condition may be deteriorating dangerously Wrigley (1946) scathingly quotes the reply of students at two London medical schools when asked how they would treat patients who were overdue When 14 days have elapsed labour should be induced According to Wrigley This reply is as fatuous as it is dangerous.' But is it ? Though we do not know the exact interval that can be safely allowed after the expected date of confinement, it appears from the few figures available to be about fourteen days though possibly this is rather too long Surely it is a very much safer plan to induce labour then than to rely on such exiguous signs as rigidity and oligohydramnios

In brief our suggested plan for managing these cases is that, except in cases where there is serious doubt about the history it is dangerous to allow a woman to exceed her expected date of confinement by more than a short period and that after that period labour should be induced What that period is we hope that further work will show but it seems to be about seven days. In trying so learn more about this problem we shall be well advised to keep in mind Cardinal Newman's dictum that the logic of facts is the most thorough teacher '

Summary

Two series of cases in which pregnancy was continued past the expected date of confinement were studied In one group labour was induced a day later by rupture of the membranes and in the other group the pregnancy was allowed to continue until the onset of spontaneous labour

The results as regards fœtal mortality were very much better in the induced group and the inductions did not appear to give rise to any additional hazard or difficulty

It is therefore suggested that, in the present state of our knowledge, these cases should be treated by routine induction rather than individually

We hope that further work will show what period, if any, can be safely allowed after the expected date of confinement At present we think it will probably be about seven days

We wish to thank Dr W R Addis for his kindness in allowing certain patients under his care to be used in this investigation, and Dr S R A Ayling, Dr B Didsbury, Dr D D Davies, Miss J K. M. Clift, and Miss B E Batty for their invaluable assistance in inducing labour in many of the cases

"REACTIONS" TO DEXTRAN

A W WILKINSON
Ch M Edin., F.R C S.E
LECTURER IN SURGERY, UNIVERSITY OF EDINBURGH

I D E STOREY
B Sc, Ph.D Edin
MEMBER OF EXTERNAL STAFF, MEDICAL RESEARCH COUNCIL

IN 1949 Thorsen reported that in Sweden the incidence of reactions of all types associated with the infusion of solutions of dextran was only 0 8%, compared with 8 2% of reactions after blood-transfusions A similar freedom from undesirable effects has been the experience of one of us (A W W) after giving more than 500 infusions of dextran solution of both Swedish (Pharmacia) and British (Benger) manufacture in the treatment of various hypotensive states in surgical patients This low incidence of reactions associated with the use of dextran has been regarded as one of its most important advantages as a substitute for plasma However, Pulaski (1951) reported a reaction-rate of 40% when Swedish dextran was injected into normal soldiers, and in 1952 Thorsen (personal communication) also found that reactions commonly followed the infusion of Swedish dextran solutions into normal volunteers No satisfactory explanation has been given of the rarity of all types of reactions when dextran is infused into patients whose blood volume has been reduced by the loss of blood or plasma, and of their relative frequency when the recipient's blood volume is normal

In 1952 a highly fractionated preparation of dextran became available in which 65% of the material was of molecular weight between 130,000 and 250,000, and more than 40 litres of this preparation has been infused by one of us (A W W) into shocked patients, with only two mild and transient reactions It was decided to repeat the experiments of Thorsen and of Pulaski by infusing some of this solution into normal volunteers to see if it produced a high rate of reactions when the blood volume was within normal limits

Methods

The five volunteers were healthy, fully grown males aged 21–38 They were recumbent for half an hour before and throughout the infusion and for a time thereafter Blood was withdrawn from a vein the left forearm, and the infusion of dextran was through the same needle, the duration of the varied from 500 ml in 47 minutes to 1 litre in 11 four of the volunteers received 1 litre, and the 500 ml of solution Further samples of venous were withdrawn about 10 minutes after the infusion finished and at short intervals during the first 6 at 24 hours, and daily thereafter The volume was measured in four volunteers on treated with Wintrobe oxalate mixture and then fuged at 3000 r p m for 20 minutes The each blood sample was allowed to clot The total protein level was determined by the micro Kje method of Ma and Zuazaga (1942) after pr with trichloro acetic acid. Albumin was determined in the filtrate after saturation of the with magnesium sulphate (Popjak and McCarthy 19 Dextran was measured by a modification of the anth method of Bloom and Willcox (1951) The bl was emptied before the infusion began, and urine collected in 6 hour specimens during the first four d and in 24 hour specimens thereafter, and the vol and dextran concentration (modified anthrone metho Bloom and Willcox (1951)) were measured The pulse and systolic and diastolic blood-pressures were repeat measured before, during, and after the infusions dextran, and the skin and general state of the volunt were closely observed

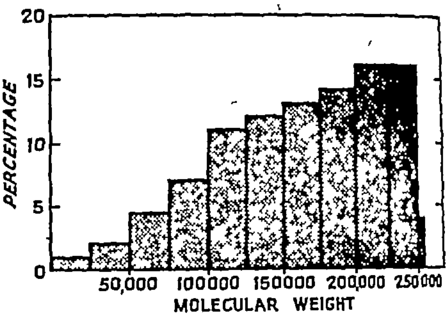

Fig 1—Distribution of molecular weights of 6% dextran solution

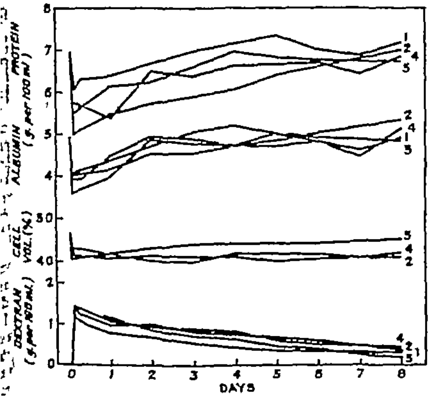
The solution (batch 3715/3/ex 225) contained dextran in 0 9% saline solution and had the mole composition indicated in fig 1 The crude dextran prepared by the action of *Leuconostoc mesenter* on sucrose

Results

"*Reactions*"

Reactions of various degrees of severity developed all five volunteers Wealing, redness, and the skin appeared in places where there was on the skin—e g, under the neckband of the shirt, tops of the socks, the trouser waistband, and sphygmomanometer cuff In two volunteers these appeared after the infusion of about 700 ml., and in others 20 and 60 minutes after completion of the infu The wealing persisted for periods of up to $2\frac{1}{2}$ h A sensation of fullness of the head was felt by volunteers, in two there was also flushing of the and in one of these puffiness of the eyelids, espe towards the end of the infusion Two noticed retrost pain during the infusion, and two experienced nau In three there was a sensation of illness and fullness the chest, which began when the skin reactions subsiding and lasted for about two hours

After completion of the infusions change in was followed by vasomotor disturbances which in volunteer were thought to be vasovagal, but only this one instance was improvement produced by the head In a second volunteer lowering the head he disturbance more severe All four volunteers who xperienced this reaction could stand up without ill ffects from about five hours after the end of the infusion ut at this time three were euphoric and all felt 'ill' n various ways They experienced 'pounding" and ullness in the head and chest which were made worse y even minor exertion, tolerance to exercise was much educed, and breathlessness developed on climbing a hort flight of stairs and persisted to various degrees or a week or more after the infusion



ig. 2—Changes in serum-total protein serum-albumin and serum-dextran levels and in packed-cell volume in the four volunteers who eceived 1000 ml of 6% dextran solution.

lood-pressure and Pulse rate

So long as the volunteers remained recumbent there ere only slight alterations in systolic and diastolic ood pressure and in pulse rate When volunteer 1 sat an hour after the end of the infusion and hung his gs over the side of the table there was a very rapid ll in systolic blood pressure from 148 to 70 mm Hg e diastolic pressure fell from 100 mm Hg to an recordable level, and the pulse rate rose from 80 to er 120 a minute; when he lay down the blood pressure d the pulse-rate returned to their previous values milar but less pronounced reactions developed in the her volunteers, except that in volunteer 2 the pulse rate ll when the blood pressure fell.

inary Excretion of Dextran

Two volunteers excreted 6% of the injected dose of xtran within two hours of the end of the infusion d within eighteen hours three had excreted 10% and e other two 8% of the dose The total quantity creted in the urine during the 48 hours after the infu n ranged from 8 to 11% after 48 hours there was o little dextran in the urine to be measured accurately

hanges in the Blood

Fig 2 shows some of the changes in packed-cell volume d the serum levels of total protein albumin and xtran during the eight days following the infusion of litre of 6% dextran solution into four volunteers e initial reduction of total protein in the serum was out equal to the initial increase in serum-dextran level ereafter the serum dextran level declined steadily; t, although within 4 days in three volunteers the levels both total protein and albumin rose above their tial values, the packed-cell volume was below the tial value after eight days

The changes during the first 24 hours after the infusion 1 litre of dextran into volunteer 4 are shown in more detail in fig 3 During the first 8 hours there were distinct changes in packed-cell volume but only slight fluctuation in the serum levels of total protein albumin and dextran Similar rapid changes in packed cell volume in the absence of reactions have been observed previously by one of us (A W W) in shocked patients after infusions of dextran and by Thorsen (1949) after the infusion of Swedish dextran.

Such pronounced alterations in cell concentration occurring during the estimation of plasma volume by the dye-dilution method caused wide discrepancies in the volumes obtained and it was thought wiser to discard the results of these direct measurements of plasma volume

The plasma volume of a normal adult male is 7% of the total body water which in turn is 60% of the 'ideal' body weight for a particular age sex and height plasma volume is thus 4·2% of 'ideal' body weight Plasma volume was calculated from their 'ideal' body weight for volunteers 2 4 and 5 who each received a litre of dextran solution From this calculated plasma volume and the observed packed cell volume before the dextran was infused the total volume of red cells in circulation was calculated Since Meyer et al (1952) using P^{32} did not find any significant alteration in red-cell volume after the infusion of a litre of dextran into normal people it was assumed that in our volunteers the total red-cell volume remained constant during and after the dextran infusion, and the subsequent changes in plasma volume were calculated from the observed changes in packed-cell volume. From these plasma volumes a good approximation of the variations in the total quantities of total protein, albumin and dextran in circulation within the vessels can be obtained The results obtained in volunteer 4 are shown in fig 4

In three of our volunteers the increase in plasma volume immediately after the completion of the infusion of a litre of dextran solution was 800 ml, 1000 ml and 1300 ml similar large increments have been reported by Haynes and DeBakey (1951) and Meyer et al (1952) Within about 2½ hours however, the plasma volume in each of our volunteers had diminished to less than that before the infusion of dextran was begun By 24 hours after the infusion the plasma volume once more had risen well above the initial volume and this increase

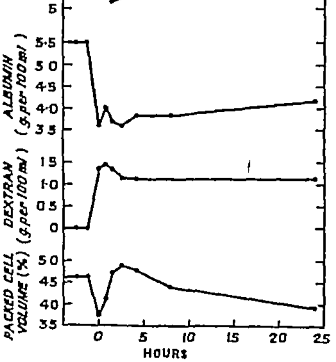


Fig 3—Volunteer 4: detailed changes in serum-total protein, serum-albumin and serum-dextran levels and in packed-cell volume during the first 24 hours after infusion of 1000 ml. of 6% dextran solution.

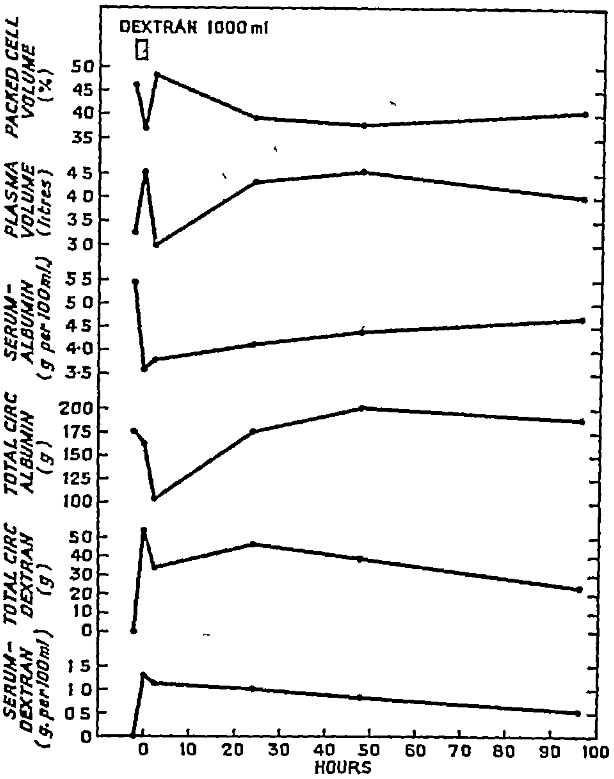

Fig 4—Volunteer 4 changes in packed-cell and plasma volumes, serum-albumin and serum-dextran levels, and quantities of total circulating albumin and dextran after infusion of 1000 ml of 6% dextran solution

was maintained at 48 and 96 hours Immediately after the completion of the dextran infusion there seemed to be very little alteration in the quantity of serum total protein and serum albumin in circulation, although the concentrations of these fractions were greatly reduced However, $2^1/_2$ hours later up to more than 30% of the initial quantity in circulation of total protein and up to more than 40 per cent of the initial quantity of circulating albumin had left the vessels During this period there was also a loss of up to 30% of the dextran present at the end of the infusion

During the period from $2^1/_2$ to 24 hours the plasma volume again increased and the total quantities of total protein, albumin, and dextran circulating in the serum also increased, but their concentrations remained low From 48 hours onwards there appeared to be more total serum protein and albumin in circulation than before dextran was administered

Discussion

There appeared to be two distinct phases in the "reactions" which the present volunteers exhibited The first was characterised by urticaria, it began during or soon after the infusion was completed and lasted for various periods up to two hours or more after the infusion ceased The second phase was characterised by vasomotor instability, it usually began after the infusion had been completed, and appeared to be related in time to the rapid increase in packed-cell volume and the underlying pronounced reduction in plasma volume, as the packed cell volume decreased and the plasma volume increased, the tendency to acute vasomotor disturbance declined

Thorsen (1949) and Bull et al (1949) explained the reduction in albumin and total-protein levels during the week after dextran infusion as being due to osmotic [illegible]sion of albumin by the circulating dextran It [illegible] it appears likely that at this time there may be more rather than less albumin in circulation. The prolonged increase in plasma volume indicated by calculations is in accord with the greatly reduced exer tolerance, precordial pain, fullness of the head, breathlessness on exertion exhibited by these volunte with the slow fall in the plasma dextran level and the small urinary excretion of dextran

Summary

A 6% solution of dextran in 0 9% saline solution infused into five normal volunteers, of whom received 1000 ml and one received 500 ml

The rapid initial increase in plasma volume, of plasma proteins, and decrease in packed-cell induced by these infusions were followed by the movement out of the vessels of up to 30% of the circulating plasma protein and infused dextran- W 12 hours this transfer was reversed, and the pl volume and the total quantities of plasma protein dextran in circulation were increased

"Reactions" were produced in each of the volunteers These reactions have been resolved two phases the first, characterised by urti developed during or soon after the infusion was comp and lasted for up to 2 hours, the second, by vasomotor instability, developed after the was completed and appears to be related to rap reduction in the volume of plasma in circulation.

We are indebted to the volunteers who submitted to investigations, and to Benger's Laboratories Ltd. for a sup of dextran solution and for data regarding its composit

SURGEON, ROYAL NATIONAL THROAT, NOSE AND EAR HO
LONDON

Tonsillectomy occupies a curious place in It is one of the commonest of all items on the ope list of any hospital, for many thousands of tonsillect are done every year in England, but every surgeon a tonsillectomy with anxiety, for the risk is always in his mind Before the late war the mortality cited one London centre was 1 in 1000, but figures do accurately reflect the difficulties, nor do they the conditions in small hospitals, where both sur and anæsthetist may be less skilled than in a centre

The account of the cases which follow form the ence of one surgeon, they were not all his own for some were under the care of colleagues, but disaster was so unusual and so tragic that it was rec in detail and discussed by the whole hospital staff therefore could fairly be said to have entered the ence of everyone on the spot, whether directly with the case or not

Before discussing the case records in detail, it might useful to contrast the risks of tonsillectomy at present time with those of twenty years ago There one risk, for instance, which has nearly disappeared chance of serious infection Before the discovery penicillin, an otitis media was quite common tonsillectomy in children, and many of the older surgeons can remember a subsequent death from meningitis Serious infection after tonsillectomy is now rare, although penicillin is seldom given beforehand as a precaution. Perhaps penicillin has made the wards safer for a serious cross infection of any kind is now unusual The anæsthetic risk also is less now when the anæsthetist is of specialist rank but more will be said about this later , a surgeon naturally cannot make expert comment on the anæsthetics of the present day but he has, at all events, as great an interest in their success as any other worker in the theatre

The risks can be divided into four groups—those at the time of operation those immediately after operation, those within twenty four hours, and those later than twenty four hours after operation

Anæsthesia

The surgeon needs for tonsillectomy a patient who is deeply anæsthetised and has had a smooth induction of anæsthesia A light anæsthesia and a troublesome induction both increase the bleeding and a glance at the patient when he is wheeled into the theatre from the anæsthetic room is enough to enable the surgeon to make a fair guess at the difficulty of operation provided that there is no peritonsillar fibrosis

Sudden death from the use of too much anæsthetic has not happened in my experience although it is a risk which might occur to anyone who considers the operation The difficulty has lain in the opposite direction, for I find the inexpert keep their patients under too light anæsthesia. Davis s or Boyle's gag is a traditional instrument and a trap for the beginner for no-one can anæsthetise an adult through the tube built into the gag if he uses ether alone and a child needs a very large flow of ether and even then steadily regains consciousness throughout the operation if he is well grown The best anæsthetic I have seen for tonsillectomy is intravenous thiopentone combined with an intratracheal tube which delivers oxygen

Risks at Operation

The risk *which is uppermost in the mind of the surgeon* is hæmorrhage Hæmorrhage at operation is likely if there has been a recent infection—e.g a sore throat, and a cold—or if there has been a peritonsillar cellulitis at any time, because of the resulting peritonsillar fibrosis.

The details of ligature of vessels in the tonsillar bed would be out of place in this article but the methods of dealing with severe hæmorrhage must be listed—they are in order a ligature introduced into the tonsillar bed with a curved needle suture of the anterior and posterior pillars, and suture of the pillars over a gauze swab If hæmorrhage is severe the operation may, rarely have to be abandoned.

A young doctor had been in bed a month before with a severe quinsy and had only recovered from the infection a fortnight before admission to hospital for tonsillectomy He bled so freely that onlookers thought he might die on the table in spite of two blood transfusions. The surgeon succeeded in removing only one tonsil but managed to stop the bleeding by ligatures over a gauze swab The other tonsil was removed two months later without incident

The mistake here was to try to remove the tonsils too soon after a quinsy Tonsillectomy is always difficult when there has been a quinsy because of the fibrosis which prevents the cut blood vessels from retracting but if an adequate time—e.g six weeks—is allowed to pass before operation is undertaken, the surgeon s task will be easier

It is unfortunately true that the neater the surgical work the greater is the risk of bleeding at the time of operation or in the first twenty four hours Serious bleeding *for example is less common after* a guillotine operation than after complete dissection This is not to be taken as a recommendation of the guillotine operation The risk of hæmorrhage after tonsillectomy with scissors is only slightly greater than after blunt dissection and there is no doubt that the patient feels more comfortable if his tonsils have been cut out with a sharp instrument I vary my practice in this detail and use scissors in London and a blunt dissector in the country, but never the guillotine The following incident illustrates the risk of sharp dissection

A surgeon of international reputation was asked to visit a foreign country shortly after the war to demonstrate his method of tonsillectomy which relies chiefly *on the use of scissors. He operated on four cases, and the onlookers said* afterwards that they had never seen the tonsils so cleanly and neatly removed Unfortunately three out of the four patients bled within twenty four hours of operation. The surgeon had of course kept all four patients on the operating table until he was satisfied that the immediate bleeding had stopped for this is the present custom no matter which technique is used.

An example of a mistake of routine is the following

A child was admitted for tonsillectomy which was undertaken on the day following admission. The house-surgeon removed the tonsils without incident but, when he used the adenoid curette there was profuse bleeding He pushed the sucker tip into the nasopharynx, but it quickly became blocked so he abandoned it and used the sucker tubing alone to remove the blood At this point the child suddenly collapsed and died Nothing was found at necropsy to explain the sudden death but inquiry showed that the child had had a temperature of 99 6 F on the night of admission. This should have been enough to make the house-surgeon postpone operation He would have been wise also to have tried pressure with gauze before he used the sucker

The general rule is that no-one should be prepared for operation if his temperature has been higher than 99°F on the preceding evening Many people have a slight *temperature on admission (possibly from anxiety in strange surroundings)*; hence a temperature of 99°F can be ignored, but a higher temperature must stop a deliberate operation like tonsillectomy

The next period of risk is during recovery from the anæsthetic The position of a patient in bed after operation is generally agreed he should be on his side with his face visible and both hands should be in front of the chest. A good way to keep this position is to flex the leg which lies underneath. If the patient is not on his side and the airway is not free, there is a risk of sudden death from asphyxia by the tongue falling back

A surgeon of considerable experience joined the Services at the beginning of the war He removed the tonsils of a patient in the usual way and returned to the sister s room for a cup of tea. Ten minutes later he went to the ward where his patient was lying and found the bed surrounded with screens He asked why this had been done and was told that it was the custom to surround the bed with screens in the general ward when a patient was recovering from an anæsthetic. The surgeon was not satisfied and went to examine the patient behind the screens. He found that he had rolled on his back and was dead.

The lesson of this case, which is recognised in most hospitals is that a patient must be watched continuously until he recovers from an anæsthetic So far from screens being used he should be left in a bed where everyone entering a ward can see him unless there are enough available nurses for one to remain at his bed When a patient begins to recover consciousness he becomes restless and coughs out the airway A trained person must be by the bedside from this point until consciousness is complete to watch the breathing and to report unusual bleeding (there is always a small amount of blood coughed out during recovery and experience is needed to tell whether it is due to active bleeding or not) Maintenance of the airway may need a tongue clip and a gag such as Mason s gag which should lie by the patient's bed together with a sucker and rubber tubing

If active *bleeding is noticed just* before complete consciousness returns the patient should be brought back to the theatre at once

A man of 45 was admitted for tonsillectomy His tonsils were removed with little trouble, and he was sent back to the ward Word, was, however, sent twenty minutes later that the bleeding was more than usual The surgeon went to the ward and confirmed the message, so the patient was returned to the theatre, where a bleeding vessel in the right tonsillar fossa was found and ligatured There was no more trouble, and the patient knew nothing of his mishap

The important fact of this story is the stage at which the bleeding was discovered If a second operation has to be undertaken for hæmorrhage, the best time is certainly before recovery from the first operation

The next story is exceptional

A girl of 11 was admitted for removal of adenoid remains The anæsthesia was not entirely satisfactory, for the child was not deeply unconscious The adenoids were, however, removed, and the patient was sent back to the ward An urgent message was sent from the ward during the next case to say that the child had stopped breathing, and that the pulse could not be felt She did not recover, in spite of emergency bronchoscopy At necropsy a piece of adenoid tissue was found in the right bronchus

The adenoid tissue had certainly caused death from shock by sudden inhalation This rare accident might have been avoided if a guarded curette had been used for a guarded curette catches with its teeth any adenoid tissue which is cut by the blade The only objection to the use of a guard is that it tears the posterior pharyngeal wall, sometimes severely

It is remarkable that the lungs are seldom injured in tonsillectomy, although the surgeon works at the entrance to the whole bronchial tree In spite of great care a small amount of blood must be inhaled at every tonsillectomy, for X rays have shown traces of 'Lipiodol' at the lung base, when gauze swabs soaked in lipiodol have been used experimentally instead of the usual tonsil swabs

The lung seems to be able to dispose of a small quantity of blood, and I know of no record in England of a lung abscess due to blood-clot Rarely, inhalation of blood can cause pyrexia for ten days or a fortnight

Hæmorrhage after Return of Consciousness and within Twenty-four Hours

Hæmorrhage within twenty-four hours after an operation is the terror of all who look after cases of tonsillectomy—surgeon, anæsthetist, and nurses alike Within an hour a healthy patient may become desperately ill, unless he has urgent and expert treatment Every surgeon has had a case where a disaster has occurred after-hæmorrhage, and it is really to arouse thought about such a complication that this article has been written, for a case of tonsillar hæmorrhage is often allowed to be forgotten as quickly as possible, to spare the feelings of those responsible The following case shows some of these difficulties

A child of 8 was admitted for tonsillectomy The operation was completed quite easily, but three hours later it was obvious that the tonsillar fossæ were bleeding The house surgeon set up a blood transfusion apparatus and gave a pint and a half of blood The bleeding continued, and two hours afterwards the child was sent to the theatre, but did not recover consciousness after the tonsillar fossæ had been tied

The mistake in this case was clearly the decision to give a blood-transfusion rather than to tie the bleeding vessel at once

A boy aged 12 had his tonsils and adenoids removed in the morning, and during the afternoon the house surgeon was called because of bleeding The house surgeon was inexperienced and thought that he could tie the blood vessel in the tonsillar fossa under local anæsthesia He therefore sprayed the throat freely with a 10% solution of cocaine Within half an hour the child died from cocaine poisoning for the cocaine had been absorbed through the raw tonsillar fossæ

The correct treatment for hæmorrhage within twenty four hours is to tie the blood vessel under general The only exception is in the case of a well disciplined adult who may allow local pressure of a sw if he has been given a small injection of morphine fir

A warning should be given against the use of sedativ in these cases, except in small doses Patients who bl after tonsillectomy seem to be unusually sensitive t morphine and the barbiturates, and I have records o two patients who died after tonsillectomy, when n cause could be found except a large dose of sedativ given in each case for slight hæmorrhage

If another operation is needed, the anæsthetist mus be expert, there is a serious risk that blood will b vomited and inhaled during induction of anæsthesia, o that a blood-clot will become dislodged from the tonsil fossa and obstruct the laryngeal orifice I have witnessed both these disasters and the promptness with which my anæsthetist, Dr F H Blackburn, handled them

The detailed method of controlling recurrent hæm rhage differs little from that already described f hæmorrhage during tonsillectomy, except that I have th practice of tying the pillars of the tonsillar fossa, besid tying the blood-vessel to make sure that the bleeding controlled

The bleeding may sometimes come from the pharynx The cause may be a small piece of tissue which has been left behind, or a tear of the wall by the curette If the bleeding has been serious enough need a second anæsthesia, the blood vessel should b sought for and tied, and a gauze pack left in the naso- pharynx for twenty-four hours The pack must b attached to a tape leading out of the mouth so that can be removed

Bleeding from the nasopharynx is fortunately rare

Secondary Hæmorrhage

Hæmorrhage after the first twenty-four hours aft operation is seldom serious, and only once in the last t years have I had to tie a blood vessel for this reason

The cause of bleeding is usually the separation of th slough from the tonsillar fossa, since this may not ta place for ten or twelve days, secondary hæmorrhage ma be delayed for that length of time The chance of hæm rhage can be guessed by the amount of slough in th tonsillar fossa If the slough is large, there is a grea risk of hæmorrhage, a clean tonsillar fossa is likely give no trouble The chance of secondary hæmorrh controls the length of a patient's time in hospital, he is sensible and knows what to do if there is bleeding can be discharged in three days, but our custom is to k an adult in hospital for six days and a child for four da

The treatment of secondary hæmorrhage is simple, it is to keep the patient in bed and to prescribe a sedati such as morphine gr 1/4 The only indications for second operation are a severe and repeated loss of b and a steadily rising pulse rate, both of which are The prevention of secondary hæmorrhage lies in prevention of slough in the tonsillar fossa, and a towards this is strict cleanliness in the operating the-

To complete the risks of tonsillectomy, it is only to report the sequence of events when a swab has left behind Every surgeon has his own method avoiding this mistake, and each method is born of h experience, for few surgeons have not had to remove swab on the day following operation A swab can ea be left in the upper part of the tonsillar fossa, where fortunately remains until it is removed I know of o one case where it was inhaled and caused a lung absc I try to avoid leaving a swab by feeling both fossæ the nasopharynx at the end of the operation, and looking into both fossæ with the help of a headlight

No doubt many of my colleagues will be able to other examples of risks of tonsillectomy, but this should be enough to act as a warning to those who that such a common operation must in time become minor operation

SERUM-CHOLESTEROL LEVELS IN ELDERLY PEOPLE LIVING AT HOME

W. HOBSON
B.Sc., M.D. Leeds, D.P.H.
ROFESSOR OF SOCIAL AND INDUSTRIAL MEDICINE IN THE UNIVERSITY OF SHEFFIELD

ARTHUR JORDAN
M.B. Lond., D.Sc. Strasbourg, M.R.C.P.
HEMICAL PATHOLOGIST, ROYAL INFIRMARY AND ROYAL HOSPITAL, UNITED SHEFFIELD HOSPITALS

CISSIE ROSEMAN

STATISTICIAN, DEPARTMENT OF SOCIAL AND INDUSTRIAL MEDICINE, UNIVERSITY OF SHEFFIELD

IT has been suggested that the serum cholesterol level influenced by age, sex, diet, and metabolic state. uch of the evidence relating the serum-cholesterol level o the presence or absence of certain degenerative con itions, such as arteriosclerosis is contradictory. For ld people only scanty data are available. In the course f a detailed medical survey of old people living in heir own homes the serum-cholesterol levels were etermined and related to age, sex, diet, and various linical conditions.

Methods

election of Group

The final group consisted of 98 men aged 66–85 and 41 women aged 61–87. The sample was drawn in arch 1948 and was a 1:30 random selection from the ood office register of men and women residing in Sheffield who had reached pensionable age (65 in men and 60 in omen). Only those living alone or with spouse were ncluded in the medical survey. Medical students (30 nen and 34 women) aged 18–20 served as controls for the serum-cholesterol determinations.

linical Examination

The old people were medically examined in their homes. Samples of blood were taken by venepuncture; the time of the day at which the blood was taken varied. Ophthalmological examinations were made at the Royal Hospital, Sheffield, by the staff of the ophthalmological department.

Nearly every person examined presented some evidence of clinical abnormality: raised blood pressure, a story of angina, evidence of arteriosclerosis, spontaneous ruising, and chronic ronchitis were very common. It was decided therefore to exclude from the study only those cases in which there was evidence of disordered thyroid function (1 case) or glycosuria (2 cases).

As a criterion of obesity the thickness of a skin fold (the dermis with the underlying panniculus adiposus) was measured on the abdomen at the level of the umbilicus in the lateral plane. The skin fold was picked up with the thumb and forefinger and held in position while the thickness was measured with callipers, which were spring loaded so that all the readings were made under constant pressure.

Radiological examination of the chest for evidence of aortic calcification was carried out at the Royal Hospital, Sheffield, by Dr. J. L. A. Grout.

Dietary Survey

Information was collected on the consumption of food and drink by each old person for a week. A spring balance and standard tablespoons and teaspoons were provided (Widdowson 1936, Beltram and Bransby 1950). The dietary survey was completed satisfactorily by 84 women (59%) and 71 men (72%).

Serum-cholesterol Determination

To 20 ml. of a mixture of acetone and absolute alcohol (equal parts by volume) 1 ml. of serum was added slowly with shaking, the total volume was made up to 25 ml with the above mixture and the flask was stoppered, shaken, and allowed to stand overnight. Next morning after further shaking the mixture was centrifuged; 5 ml of the supernatant fluid was evaporated to dryness, the dry residue was redissolved in 5 ml. of chloroform and the tube was stoppered and placed in a waterbath at 20°C for several minutes. 3 ml of a fresh acetic anhydride-sulphuric-acid mixture (10:1 by volume) was then added, the tube was restoppered, the contents were mixed, and the tube was placed in a waterbath at *exactly 20°C in the dark for precisely 20 minutes*. The optical density was then read photo-electrically with an Ilford no. 204 (Tricolour Red) filter. A standard solution of cholesterol in chloroform was taken through the later stages in parallel with each batch of tests.

The serum cholesterol levels were also determined by the same method but using Bloor's original method of extraction (Bloor 1916). Others were determined by substituting for the acetone-absolute alcohol mixture a mixture of ether and absolute alcohol (1 part to 3 parts by volume).

P	Less than 1%		Between 1% and 2%	
Logarithmic mean serum-cholesterol level (mg per 100 ml)	268	310	211	233

Results

Methods

Comparisons were made between the three different methods of extraction by applying more than one method to the same serum In studies of 53 sera no statistically significant differences were found between the results yielded by the different methods of extraction

Age and Sex

The serum cholesterol values for all the old people were plotted as a frequency distribution for each sex and were skew, plotted on semi-log paper they appeared to be lognormal This was confirmed by the calculation of Fisher's g_1 The numbers in the control groups were insufficient to establish the type of distribution, we have assumed the distribution to be lognormal There is evidence from the work of Wootton, King, and Smith (1951) that the distribution of whole-blood cholesterol level in the age group 18–50 follows a lognormal distribution For these reasons the logarithms of the serum-cholesterol values have been used for all the calculations, in all the diagrams a logarithmic scale has been used for the serum-cholesterol values The relation between cholesterol value and age for both the old people and the controls is shown in fig 1

There is a significant difference between sexes both in the old people and in the controls (table I), women having, on the average, a higher serum cholesterol level than men of the same age In both sexes there is a significantly higher serum cholesterol level in the old people than in the controls (table II) The serum cholesterol level is lower in subjects over the age of 70 Analysis of variance shows that the differences are not significant at the 5% level

The subjects investigated may be regarded as a representative group of old people aged over 60, and the serum cholesterol results provide limits for "normal" values If the normal range be regarded as the mean of the logarithmic values plus or minus twice its standard deviation, the results reconverted into milligrammes of cholesterol per 100 ml of serum yield the following values for people over 60

Men mean 268 range 176–409
Women mean 310, range 200–481

Another method for the presentation of normal range has been suggested by Wootton et al (1951) The outer or 1% limits enclose 98% of results and the inner or

lateral radiographs as having calcification of the aorta and 30 men and 37 women showed depressed crossings of the retinal blood vessels. It was impossible to establish any statistically significant relation between the serum cholesterol level and the presence or absence of any of these conditions.

Blood pressure

Scatter diagrams showing the relation between the serum-cholesterol level and the systolic and diastolic blood pressures did not show any correlation.

Eye Changes Associated with Ageing

In 175 of the subjects (78 men and 97 women) the eyes were examined 31 men and 23 women showed well marked arcus senilis 2 men and 5 women had senile atrophy of the retina; and 19 men and 35 women had senile cataract No significant relation was found between the serum-cholesterol level and the presence or absence of these conditions.

Discussion

The blood specimens were taken at various times of the day irrespective of meals and rest periods. Ordinary meals are known to have little effect on the serum cholesterol level. Keys et al (1950) found no difference between the serum-cholesterol levels of specimens taken under basal and non basal conditions although Groen et al. (1951) found that infections, trauma severe exercise and emotional tension could affect the serum cholesterol level.

Some modifications were introduced into the Bloor (1916) technique for determining serum-cholesterol levels. Extraction of the lipoids with a cold acetone alcohol mixture overnight appeared to give results comparable to those given by extraction with an ether alcohol mixture and with greater safety from fire and peroxide explosions Sperry and Brand (1943) discussed the need for careful control of the temperature and of the time allowed for colour development in the Liebermann Burchardt reaction. D.A Podmore (personal communication) found that the greatest development of colour was obtained by using 55 parts of cholesterol solution in chloroform 30 parts of acetic anhydride, and 3 parts of concentrated sulphuric acid Free cholesterol gives less colour than does the equivalent amount of cholesterol in ester form and the Liebermann Burchardt reaction applied directly to an extract of serum gives higher results than those obtained if colour development took place after hydrolysis of the ester (Gardner and Williams 1921 Reinhold 1936 Sperry and Brand 1943, Kibrick et al 1951) Keys et al (1950) found this difference to be 2 1 mg per 100 ml but did not give full details of their technique Reinhold (1936) and Podmore (personal communication) have shown that the difference depends on the conditions under which the colour is developed the important factors being the temperature the proportions of the reagents, and the time allowed for development of the colour

The results show that the elderly women had a higher serum-cholesterol level than men of the same age The finding of a higher serum-cholesterol level in the old people compared with the young people is in general agreement with the findings of Barker (1939) Kornerup (1950) and Keys et al (1950) in men and of Mühlbock and Kaufmann (1938) and Gram and Leverton (1949) in women Sperry and Webb (1950) found that in 12 people (6 men and 6 women) the serum-cholesterol level had risen 15–30% after about fourteen years and in 10 people (8 men and 2 women) the same interval of time had produced no significant change the age ranges for these subjects at the end of the experiment were 38–57 for the men and 35–54 for the women Page et al (1935) studied the serum-cholesterol level of 67 men aged 21–101 and claimed that there was no significant change with increasing age but the regression line for the data of Page and his colleagues between the ages of 21 and 79 calculated by Gertler et al (1950) showed a rise of the serum-cholesterol with age which was significant on the 5% level. Barker (1939) suggested, and Keys et al (1950) found that with the onset of old age in men the serum-cholesterol level began to fall; the present study does not contradict such a finding in both men and women. If the higher serum-cholesterol levels were associated with lessened expectation of life after middle age, there would be a selective removal of those persons with the higher values, which would lead to a fall in the mean serum-cholesterol level in the older age groups

Hildreth et al (1951) and Keys (1952) have shown that extreme variation in the intake of fat changes the serum cholesterol level Groen et al. (1951) have shown that variations in the cholesterol content of the diet between 1 5 mg and 900 mg per day can cause variations in the serum-cholesterol level Gardner and Gainsborough (1928) found a similar effect The range of dietary intake of fat was greater in the women than in the men and this may explain the apparent correlation between the serum-cholesterol level and the intake of fat in the women but not in the men We also found an over all correlation when the two sexes were taken together These results indicate that even the variations in intake of fat on normal diet may be sufficient to alter the serum cholesterol level

The finding of a relation between the intake of alcohol and the serum-cholesterol level is difficult to comment on Wilens (1947c) expressed the opinion that the lower incidence of atherosclerosis observed in alcoholics compared with non-alcoholics was the result not of alcoholism but of associated differences in age, blood-pressure, and nutrition, to these might be added race and diet Some of these factors may well be involved in the relation between alcoholism and the serum cholesterol level

There was no statistically significant relation between body-weight and serum cholesterol level, but weight alone is not a true measure of obesity Keys (1949) has found a better measurement in the thickness of an abdominal skin fold, his results indicated that fatter men tended to have higher serum cholesterol levels These differences analysed by the only statistical methods open to us were not significant, but possibly a more refined technique would have demonstrated a significant difference The analysis of our data suggests that there is a relationship Such a finding is of considerable interest because a high incidence of atherosclerotic complications in the obese is a well-known experience of life-assurance companies, and Wilens (1947a and b) found that severe atherosclerosis is ten times commoner in fat people than in thin In experiments on animals Firstbrook (1951) found that the greater the degree of hypercholesterolæmia the more rapidly did atherosclerosis develop, and that the atheromatous condition developed more slowly in thin animals than in fat There is strong evidence that in man also atheromatous conditions are commoner with a high serum cholesterol level (Gubner and Ungerleider 1949, Duff and McMillan 1951, Katz 1952) We were unable to demonstrate any relation between the serum-cholesterol level and manifestations of atherosclerosis

Our results did not show a significant association between the serum cholesterol level and the blood-pressure

No relation appeared to exist between the serum-cholesterol level and the presence or absence of arcus senilis or of senile cataract, the number of cases of senile atrophy of the retina was too small for any reliable conclusion to be drawn Garn and Gertler (1950), in their survey of Aleutian islanders, found that the serum-cholesterol level was no higher in those with well marked arcus senilis than in those without

Summary

The mean serum-cholesterol levels in elderly men and women living at home were significantly higher than in control groups of younger people

For both the young and the old the mean serum cholesterol levels in the women were significantly higher than in the men

The mean serum cholesterol level tended to decrease after the age of 70

The normal range for the serum cholesterol level determined by the technique described was

Men aged 60–85 176–409 mg per 100 ml
Women aged 61–87 200–481 mg per 100 ml

There was a significant correlation between the dietary intake of fat and the serum-cholesterol level in the women but not in the men The combined results for the two sexes gave a significant correlation

Lifelong teetotallers had, on the average, a significantly higher serum cholesterol level than had heavy drinkers

There was a significant correlation between the thickness of an abdominal skin fold and the serum cholesterol level in the women but not in the men The combined results for the two sexes gave a highly significant correlation

No relation could be established between, on the one hand, the serum cholesterol level and, on the other hand, intermittent claudication, angina, cerebral thrombosis, aortic calcification, depressed crossing of retinal blood-vessels, arcus senilis, senile atrophy of the retina, and cataract, or the height of the blood-pressure

We wish to thank Dr J L A Grout for radiological examinations, Dr H Droller for clinical examinations Mr E G Mackie and Mr K Rubinstein for eye examinations Dr P W W Gifford and Sister H Greer for examining the controls, Mr D A Podmore and Mrs C D P Jefferies for help in determining the serum cholesterol levels, Mr A E Foster, Miss P M Ashton, and Miss A A Hutcheson for technical and clerical assistance, and Dr E R Bransby, of the Ministry of Health who arranged for a team of dietitians from the Social Survey to make the dietary investigation under the direction of Mrs Barbara M Osborne We should like also to thank those general practitioners, old people, and medical students of Sheffield who by their coöperation made this investigation possible, and the Nuffield Foundation for the generous grant which paid for the expenses of the investigation

THE INSULIN MYTH

Harold Bourne
M R C S, D P M
JUNIOR HOSPITAL MEDICAL OFFICER, THE FOUNTAIN HOSPITAL, LONDON

The outstanding importance of schizophrenia as a biological and social problem makes the critical evaluation of its treatment a matter of the first interest and no mere parochial concern for psychiatrists In this paper I shall try to show that there is no sound basis for the general opinion (as stated, for example, in a refresher course by Sargant and Slater in 1951) that insulin-coma therapy counteracts the schizophrenic process in some specific manner, and that its therapeutic effects are greatly superior to those obtainable by electro-convulsant therapy (E C T)

A treatment for schizophrenia may be evaluated by its immediate and remote effects on (1) early cases in which spontaneous remissions make the value of any therapeutic procedure formidably difficult to assess, (2) dilapidated chronic cases in which the extreme unlikelihood of spontaneous improvements makes even small groups of decidedly positive results significant, and (3) individual cases observed over long periods with repeated administration of the treatment

The Early Case

It was soon recognised that useful results with insulin coma were unobtainable after two or three years of uninterrupted psychosis and the popularity of the thod depends entirely on its supposed value in recent es. Usually, in the accounts of its application eries of patients treated by insulin coma is compared ıer with a series treated in the pre-shock era or with parallel untreated or E.C.T treated, series. These allel series, though seldom comparable in more ın a few respects, are often regarded as true controls. reover where the series compared do include cases longer standing no distinction is made between those continuous and those of intermittent psychosis The ole method is riddled with sources of fallacy deriving m the nature of the disease, and from the nature of ulin treatment itself.

llacies Arising From the Nature of Early Schizophrenia

l The diagnostic criteria are highly subjective and riable and certainly very different from what they re in the past, when recovery implied misdiagnosis nd and Bruceland (1937) in a study of all patients mitted to a Philadelphia mental hospital in 1927–28 ınd that of 116 cases finally labelled schizophrenic er five years, only 10% had recovered and 31% had overed or improved but if the early diagnosis s accepted, the rates for schizophrenia rose to 20% overed and 40% recovered or improved. Nowadays ulin coma is often begun on a suspicion, perhaps lstered by a Rorschach or other test and almost reports fail to specify the diagnostic determinants d their distribution The increased readiness to gnose schizophrenia in favourable cases is reflected Malzberg s (1943b) finding that, in New York State, e incidence of schizophrenia and the discharge rate e both rising

2 Halliday (1946) has traced the profound changes the quality *and relative incidence of psychogenic* nesses over the past 70 years, and it is quite likely at the schizophrenic psychoses have been affected. deed the great changes emphasised by him in the rly environment of the infant whose experiences are pecially prominent in the psychopathology of schizo renia, are particularly suggestive. As a result it ay well be that the basic prognosis and diagnostic iteria have been altering in such a way as to invalidate e direct comparison of contemporary results with ose of the pre-insulin era

The immediate prognosis of present-day untreated rly schizophrenia is altogether problematic but the llowing summary of a series of 376 schizophrenic ldiers, 186 of whom I followed up by letter two years ter may suggest that acute schizophrenic illnesses e becoming more benign Of the 376 84% were dis arged, nearly all within nine months, as recovered improved sufficiently not to need further hospital re, and the *follow up indicated no strikingly extensive* rapid relapse-rate For 156 cases treated with C T the corresponding figure was 83% of 15 treated th insulin coma, with or without E.C.T., 9 resumed dinary life while for 205 untreated cases the figure s 88% It should be added that in both treated oups a substantial number of psychoses subsided long ter the treatment could have been responsible

It is possible, therefore, that apart from the increasing tection of earlier and milder cases, the scales are ing deceptively tipped in favour of insulin by some ange in the short-term prognosis

3. The influence of nuances of environment on the urse of schizophrenia involves so many imponderables hich cannot be isolated or controlled that to compare sults at different times or places may be quite invalid. uite apart from any theoretical arguments in favour of organic pathogenesis or predisposition for schizo- renia environmental factors have an overwhelming actical significance—as is shown by its changed inci ence in European and African stocks transplanted to e United States of America (Malzberg 1940, Carothers 1947) The importance for the outcome, of environment during treatment was stressed long ago and can be seen in gross form by contrasting the dereliction of chronic schizophrenics in backward institutions with their appearance in hospitals promoting liberty and social life Clearly it is impossible to control, and mistaken to dis regard the less obvious but equally influential variables affecting the response of the schizophrenic to treatment: the very same attendants will change in personality over the years and the transitory junior nurse and doctor the other patients, or even the weather may all conceivably exert a decisive twist Kalinowsky and Worthing (1943) obtained very different results with E C T given in the same way at the same time to schizophrenics in two different hospitals.

Thus inherent in this disease and in the therapeutic environment, are numberless uncontrollable factors which taken together render it insurmountably difficult to validate any method of treatment by simple comparisons of results in early cases in different decades or places, or by different workers—unless possibly a near 100% recovery rate were in question which arises neither with insulin nor convulsion therapies.

Fallacies Arising from the Nature of the Therapy

1 Insulin coma produces drastic modifications in the subject s environment which may well favour improvement in a non-specific manner Insulin patients tend to be an élite group sharing common perils and privileges, they receive an extra diet, are anxiously watched day and night and have concentrated individual nursing for a five hour daily treatment period over two or three months, as well as the attention of a doctor for three of these hours In most mental hospitals they are given, at *a conservative estimate 50–100 times as much medical* and nursing care, measured by the clock, as the general run of non insulin treated patients. A relevant observa tion by Rubé (1948) records a decline in remission rate of schizophrenia with sulphosine therapy in a Paris hospital, from 35–40% in 1932 to 15–20% in 1939 as the novelty of the method and the staff's initial enthu siasm wore off and he suspects a similar development in insulin clinics as routine replaces drama. Cossa et al (1948), recording just such a change, wonder naïvely whether their post war insulin lacks some non hypo glycæmic factor

Few mental hospitals, even today, are able to offer recently admitted patients (let alone schizophrenics who have been in longer than a few months), much more than custodianship rug making the cinema and a chat every week or two with the doctor Inducing two or three electric convulsions a week hardly alters this setting to an extent comparable with the insulin-coma régime—*a fact to be remembered when assessing results.*

2 The mode of selection of cases for insulin coma is biased Reports are uniform that the best results are obtained where without any treatment, the prognosis would be most favourable so except in the unusual circumstances of it being freely available for all cases selected for treatment are only those considered most likely to benefit—that is to say, to get better anyway It is no wonder that an impression" is so often met that the quality of remission after insulin is superior It would be surprising if it were otherwise Practically all reports comparing insulin favourably with E.C T omit to say how patients were chosen for either treatment; but they contain details from which this bias can be strongly suspected.

3 The concomitant administration of E.C T., so often reported obscures even more the specific action if any of the insulin coma itself Induced convulsions are in fact now so often casually mentioned as an ingredient of the coma technique that it cannot be assumed with certainty that recent publications on insulin may not just as well be taken to mean results with E C T

4 Improvements in patients treated with insulin or E C T cannot be attributed simply to the method unless they occur within some limited time, but most reports ignore this Alexander (1944) believes the picture would be much less favourable if improvements appearing more than thirty days after treatment were excluded

The Fallacies Avoided?

Altogether, the evaluation of insulin coma in early schizophrenia presents extraordinary difficulties deriving from both the nature of the disease and the nature of the treatment, and attempts to by-pass the pitfalls are few

Lipschutz et al (1939) designed an experiment to compare insulin with saline injections, both with and without "intensive resocialisation," to assess the relative importance of insulin, of coma, and of extra attention for the outcome But as they treated fewer than 30 cases, only 5 of whom received saline, and only 7 of whom were denied "resocialisation," the positive conclusions reached do not seem justified

Sillman and Terrence (1943) gave 112 schizophrenics daily nitrogen inhalations for one to three months to produce coma and extensor spasms, and some 20% remitted They contrast this with 52% improvements in 62 of the "nitrogen failures" subsequently given insulin coma, E C T, or both, and deduce that the benefits of shock therapies cannot be explained by special attention, fear of death, anoxia, and so forth They give no clinical details, no reason for only 62 of the failures receiving shock treatment, and no account of what became of the rest, so that it is not conclusive that the nitrogen and other results differ significantly

Can all the difficulties be overcome? Penrose and Marr (1943), when assessing shock therapies in Ontario State hospitals, devised an ingenious method for eliminating variability in diagnosis, symptomatology, and estimation of improvement They constructed tables (like life assurance tables) to enable comparison of the number of treated patients remaining in hospital on any given date with the number to be expected without treatment, based on a control method by sex, age on first admission, and lapse of time since first admission, but not by diagnosis, since (as they illustrate) certain diagnoses predominate completely at particular age ranges From this, they confirmed that over a period of two to three years, the shock treatments produced definite benefits in affective psychoses but almost none in 1041 patients diagnosed as schizophrenic, and in these, if there was any benefit at all, it was with convulsion therapy rather than insulin

INSULIN COMA VERSUS E C T

Being concerned here only to expose a myth, I shall not deal with E C T technique in schizophrenia, except to mention that its casual administration without formulated principles is a waste of time

Favourable accounts usually appeal for adequate dosage, and the course recommended, for instance, in a popular British textbook (Sargant and Slater 1947) is altogether insufficient Danziger and Kindwall (1946) calculate statistically that 26 convulsions is the minimal course, whereas Kalinowsky and Worthing (1943)—when describing in 200 cases results as good as those quoted as the best obtainable with insulin by Kalinowsky and Hoch (1946) in their standard book—insist on 20 Their diminished success in another hospital for voluntary patients, and also the poorer prognosis of their less florid cases, show how easily simple comparisons may mislead However, Hamilton and Wall (1948) report 100 such cases 67% of whom were at home, 43% recovered between eighteen months and six years after E C T, this result contrasts favourably with their experience of ten years before (though this contrast, as already explained, may have more than one interpretation) Strong evidence of the benefits of convulsion therapy is contained in Dedichen's (1946) statistical analysis of shock treatment in all Norwegian mental hospitals The few insulin treated cases briefly presented disclose incidentally that of 128 "pure" schizophrenics ill more than a year only 5 remitted

Of the innumerable reports on insulin-coma thera only some of the best known, careful, and typical ca be considered here, since the vast majority are mo tonously illustrative of the fallacies listed above Th by Ross and Malzberg and others, appearing since 1 on its use in the 19 New York State hospitals, ha undoubtedly had most influence in promoting its These cover 1039 insulin-treated, 1140 leptazol-conv sion-treated, and 1039 untreated controls, but distribution of diagnostic and symptomatic data w might show the groups to be comparable are not gi and there is much internal evidence to suggest, in that they are not comparable Some occurred in 65% of the insulin group (varying in hospitals from 35 to 91%), but in only 26% of controls, this, for an unselected sample, is low Improvement was seen in only 35% of the group which again seems surprisingly low until a tion from their tables reveals that only 15% of been ill for less than a year Also the number of c sions in each case is not given There are some anomalies Thus the control group's mortality (4%) greater than that in the insulin series The recovery (1 6%) in the leptazol series was under half that of controls, and the "much improved" rate (9·9%) also less—findings which show that the groups have been selected at random and were not prog similar In fact, a later account by Malzberg (1943 E C T in the same hospitals gives results 3–4 times than in the original convulsion-treated series. Also is evident from the two-year follow up report some insulin-treated cases received leptazol—how is not stated Finally, a 1944 report on insulin from the same hospital group shows a 58% discharge-rate untreated cases (Temporary Commission on Hospital Problems 1944), which deprives the improvement in the original controls of any meaning

Danziger and Kindwall (1946) find that, per 100 sions, the expectation of recovery in the "most able three months" is 1 5 for untreated 34 for E C T -treated, and 45 for insulin treated, less of duration of illness"

Before accepting the apparent superiority of insulin it be noted that (though clinical details are not given) 78% their 83 insulin patients had been ill for less than two compared with 63% of the 205 E C T cases thus there ably was some mode of selection, not specified, fo treatment Secondly, E C T was only given twice sometimes with interruptions, and petits mals were co as treatments Again, they take their figures for untreated category from discharge rate tables for all State hospitals in 1933—a comparison which has snare mentioned including different criteria of recovery diagnosis, and length of illness on admission Even tables, however, indicate that at three years the dis rate has risen to 32 6%—which can stand quite res beside results three years after insulin treatment At the results of these workers show a hastening of recov but they do not hesitate to ascribe this specifically to insulin coma rather than to the non specific treatment tion, since, they claim that treated patients had "no (except during actual treatment) not given to other pat and not ordinarily given in public institutions. therapy was of the most casual and superficial type

Insulin is strongly favoured by Linford Rees (1 in a widely quoted British study He compares E C T, and electronarcosis (E N) by the immediate come and follow-up of 208 courses of treatment in "experimental population" of 160 schizophrenics assessed separately the 97 insulin, 72 E C T, and 39 courses, so several cases find a place in more than group

In a wide range of features the groups corresponded, whether these were 160 consecutive schizophrenic admis over a period or whether they were somehow chosen fr larger population is not clear In the absence of infor about dosage, it may be surmised, from the poor results eir similarity in cases with poor or good prognosis, that E.C.T as inadequate by the standards quoted above Also there o some odd numerical discrepancies Thus in 18 patients all ree treatments failed accounting thus for 54 of the 208 ourses, and leaving only 154 courses for the other 142 patients that 12 at most of these could have had two treatment urses. Yet it is stated that 21 recovered with insulin after ilure with E.C.T or E.N When the percentages on which bases his conclusions are reconverted into whole numbers, any of the conclusions seem doubtful. The relapse-rate ter recovery is 7% with insulin in contrast to 33% with N ; but conviction melts when the E.N recoveries are seen number 3 in all The percentages demonstrating the periority of insulin in prognostically favourable cases refer a mere dozen or less in each group

Nielsen et al. (1942) described 316 schizophrenics each eated with 40 insulin comas and 10 convulsions and bitrarily selecting 100 of them by admission dates, ey compared them with 100 controls similarly chosen om admissions between 1931 and 1937, matching in ge and duration of illness They found no evidence of nefit in the treated group

LATE EFFECTS

Of the more remote effects of insulin some background provided by Blair's (1940) review of published work the prognosis of schizophrenia ' An average of 40% cases admitted to mental hospitals recover or prove .. relapses occur in about 20% of the cases scharged as recovered or improved of which approxi ately half are permanent."

In Ross and Malzberg's two year follow up 45% still owed some improvement 27% being recovered or much proved Bond and Rivers (1942) report a recovered or much improved rate of 55% at the end of treatment fall g to 31% in three years This three-year rate was still ice as high as the rate in 1937 at the same hospital; but en if the contrast were valid, the influence specifically of sulin would remain uncertain. Gralnick (1946) compares C.T in 208 with insulin in 158 schizophrenics and finds in vour of insulin, though, like others, he fails to give details method of selection for either treatment ages duration of ness in each group clinical features, or relapse rates. In a rvey (1945) of seven years experience with insulin in 554 ses, he finds that half the total on parole are back in hospital tween the fourth and sixth year and after six years, 73% back. He observes that the results bear no relation to the mber or duration of comas and infers that it is the insulin atment situation which matters It is noteworthy that eudenberg (1947) who gave E.C.T where there was no sponse after 20 comas, goes on to insist on prolonged courses insulin treatment for better results.

Rennie (1943) of Johns Hopkins considers that in a odern private institution the results are little different th and without insulin Similarly Gottlieb and Huston 943) found no significant difference at the end of four ars in two groups of schizophrenics, 66 insulin treated d 132 having only some psychotherapy They state at the groups were clinically alike but do not mention ndom selection Indeed this seems to be an endemic ficiency in insulin studies.

In a later contribution (1951) 128 cases having brief psycho rapy with defined aims are compared with 65 receiving insulin comas and 143 having E.C.T ; the groups were milar but for a slight excess of catatonics having E.C.T er four years, no important differences in results were at y time discernible and none emerged even when early ses of acute onset were studied separately

Libertson (1941) relating experience since 1937 with insulin one hospital compared 165 cases with a—prognostically—st unfavourable control group admitted simultaneously was astonished to discover no difference in results by 1941 d a close resemblance in 50 insulin and 41 controls with less an six months illness.

Roberts (1942) compared 74 male patients 46 of whom had nvulsion as well as insulin-coma therapy with untreated ntrols matched for age duration, and diagnostic category d observed no difference in outcome after two years, though transient improvements were 2 75 times commoner in the treated group.

Palmer et al (1950) present a very discouraging survey of 303 schizophrenics at one hospital Of 182 insulin treated patients who had not previously received E.C.T only 34% were discharged, while between eighteen months and six years later only 20% were still out of hospital and only 6% really well Of 183 who had not responded to E.C.T only 17 8% were discharged; and of 100 patients who did not respond to insulin, 15% were discharged after E.C.T Insulin courses were of 50 comas, and they had 2 deaths The E.C.T dosage is not stated.

In the light of the evidence so far presented, and apart from other considerations set out below it is clear that the justification is slender indeed for the way in which money and staff are expended on clinics for insulin coma Insulin offers the schizophrenic no long term benefits at best it hastens improvements that would occur anyhow with simple care in hospital, and which could be accelerated at least as well with E.C.T and there is no evidence that this uncertain benefit is attributable to the insulin itself and not to the insulin treatment situation. If the latter is the operative factor, its effects could surely be reproduced by some more rational and less hazardous means.

The Chronic Case

The extraordinarily few accounts of the use of insulin coma in long-standing schizophrenia all date from the early years of its use, when occasional cases of several years duration also appear as failures scattered in other reports.

Rossman and Cline (1938) claimed that of 52 cases ill an average of over four years, 83% improved 40% being recovered or much improved, but this contradicts all subsequent opinion, and indeed, if reproducible should have reduced the mental hospital population markedly Barker (1939) treated 10 Negro men who had been ill for an average of seven years (but whether continuously or in hospital is not stated) and of 13 completing the course 4 were ill less than three years, 1 died, 3 improved, and 4 left hospital; he draws conclusions by converting these figures into percentages. Fröshaug and Thomstad (1938) treated 32 women with an average of eight years psychosis The single case with " full remission was ill less than two years; 4 cases had ' good remissions " but none could leave hospital and one certainly remained hallucinated, the effect being, chiefly quieter and cleaner behaviour 6 showed partial remission with even less benefit and there were 10 instances of some transitory reductions of symptoms lasting a few days or weeks.

The general view is thus justified that insulin has no place in chronic schizophrenia but there is ample evidence that E.C.T can set off profound, if incomplete restorative changes in this most stagnant of conditions.

Moore (1943) selected 37 chronic schizophrenics of an average nine years standing all severe behaviour and nursing problems, and gave them thrice-weekly E.C.T for two to three weeks, followed by maintenance dosage and in 26 there was no question about the value of continuing the treatment —they became sociable and employable while appetite, sleep and faulty habits were almost uniformly controlled. Shoor and Adams (1950) relate that during three months intensive trial of E.C.T in the most refractory female ward of a mental hospital, the character of the ward changed radically from that of a chronic disturbed ward to that of a quiet chronic ward with a 90% reduction in sedation and restraint. Fergus (1952) gives an excellent account of what can be achieved with E.C.T in chronic schizophrenia.

Clearly the longer the psychosis endures unfluctuating over the years, and spontaneous recovery or chance improvements with treatment become less likely the probability grows that E.C.T counters the disease process in some specific way while the therapeutic activity of insulin and its superiority to induced convulsions become still more clearly mythical. Yet, nowadays, when E.C.T can bring about improvements that would have been astounding fifteen years ago in wards with schizophrenics in their most chronic state, a widespread apathy exists about its possibilities in these and in recoverable cases

The Individual Case

Perspective in the treatment of schizophrenia requires appreciation of its natural course in terms of long spans of time It may occur as single or widely separated episodes without sequelæ, or as recurring episodes with residual damage, sometimes finally amounting to gross personality destruction, or it may never remit after the first manifestation Often it is impossible to decide which of these developments is taking place and so, where some somatic interference is attempted therapeutically, repeated response acquires a significance that an isolated ensuing remission cannot have It is often asserted that schizophrenics that have recovered after insulin coma should be treated again if they relapse, but anything beyond the scantiest experience to bear this out is not on record With convulsion therapy on the other hand, relapse after withdrawal, and repeated improvement, are commonly seen in all phases I hope in due course to publish studies showing that the schizophrenic patient may be as dependent on E C T for a normal existence as a diabetic is on insulin

Summary

Schizophrenia presents a major medical and social problem, and the widespread belief in the indispensable value of insulin treatment is a matter of general concern

The difficulties of assessing any treatment in schizophrenia, and in particular, insulin coma, are discussed

In face of these, the evidence for the value of insulin treatment is unconvincing From the point of view, in turn, of the early case, the chronic case, and individual case studies, there is no proof of any specific therapeutic effect, and the long term prognosis is in no way influenced

Insulin certainly offers the schizophrenic no more benefit, and perhaps considerably less, than does E C T

It has been estimated that congenital abnormalit of the vitello-intestinal duct occur in 1–2% of peo (Brennemann 1948) A review of 144 cases in which t whole length of the persistent duct was patent show that of the 132 cases in which the outcome was k 46 (35%) were fatal, of 30 cases complicated by pr of the small intestine through the umbilical fistula (87%) were fatal, even in the cases without this gr complication the mortality was 20%, and the ra of males to females was about 5 or 6 to 1 (Scalettar et

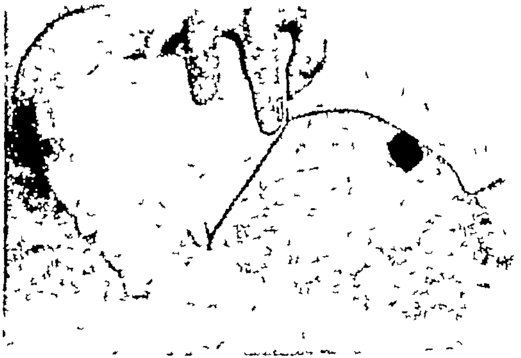

Fig 1—Raspberry-like tumour at navel

1952) Garrett (1918) reported the abnormality homozygous female twins

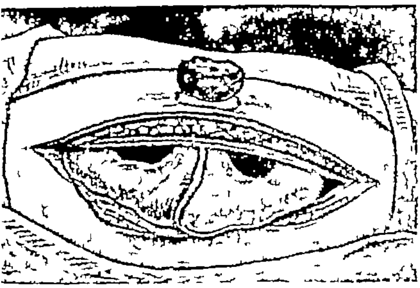
EMBRYOLOGY

In early embryonic life portions of the yolk-sa included in the embryo to form three separate part the intestinal tract foregut, mid gut, and hind The connection between the mid gut and the yolk proper becomes constricted and drawn out to form vitello-intestinal duct At about the fifth month fœtal life this duct is cut off from the mid gut, exceptionally it may remain patent as a constituent the umbilical cord, or its proximal part may persist in about 2% of people, as Meckel's diverticulum. the duct is normally obliterated, that part of the that runs in the wall of the duct disappears also, proximal part persists as the superior mesenteric

CASE-REPORT

In the following case, successfully treated by the vitello-intestinal duct persisted after birth lumen patent and its distal mucosa prolapsed, fo "raspberry" tumour or enteroteratoma The intestinal artery was represented by a fibrous cord

A male infant was delivered at full term on Jan. 30, There was no history of maternal illness in early p which was uncomplicated throughout The baby 7 lb 1 oz at birth and had a healthy brother aged 3 There was no history of congenital defect in any



g. 2—Structures found at operation : patent vitello-intestinal duct and remains of vitelline artery

e family The neonatal period was unusual in that the nbilical cord did not separate until the fourteenth day, aving a bright-red nodule which, in the next day or two creased in size to nearly 1 in in diameter There was a ttle serous and mucous discharge from the surface of the ass but meconium or fæces were never seen. There was no owel or urinary disturbance The baby was admitted to the ediatric department of this hospital at the age of 18 days.

Examination—His general condition was good The mbilical area showed a red raspberry like mass about $^{3}/_{4}$ in diameter (fig 1). The size of this tumour varied from in. to nearly 2 in. in diameter sometimes from day to day ccording to the amount of prolapsed intestinal mucosa A nall dimple-like depression could be discerned in its centre nd a probe passed into it revealed a patent duct leading down nto the gut Lipiodol 10 ml. injected into this dimple was hown radiographically to pass into the lower ileum and, wenty four hours later into the colon A patent vitello ntestinal duct with raspberry tumour (enteroteratoma) was iagnosed.

Operation.—As after a period of observation, there was no ecal discharge or obstructive symptom and the child was riving it was decided to postpone operation. He was admitted at the age of 6 months. The tumour was rger but, apart from this, he was healthy The operation as done under ether and oxygen anæsthesia. The abdomen as entered through a right paramedian incision with its ntre at the level of the umbilicus. A thin walled track in. in diameter stretched from the umbilicus to the ileum $^{1}/_{2}$ in. from the ileocæcal valve. To the right of this was a un fibrous cord stretching from the umbilicus to the ileal esentery close to its junction with the mesenteric border of e bowel (fig 2) This cord, the remains of the vitelline rtery though lying in close apposition to the peritoneal urface of the patent duct was nevertheless quite separate om it and thus formed a highly dangerous potential cause of ternal strangulation, because a loop of bowel could easily ip between the duct and the cord It was excised together with the vitelline duct The vitelline duct was divided about 1 cm from the ileum and inverted with two layers of fine catgut without narrowing the bowel lumen The remainder of the duct with the umbilicus was excised through a circum umbilical incision. The vertical incision was closed in layers and the umbilical defect repaired with the fashioning of a new umbilicus (fig 3)

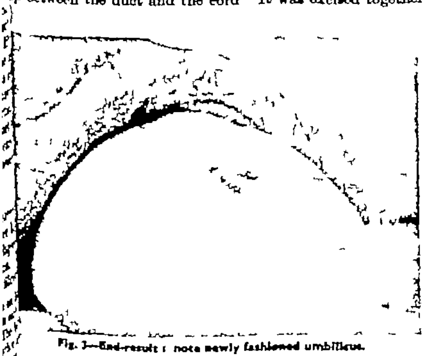


Fig. 3—End-result : note newly fashioned umbilicus.

Convalescence was uneventful, except for some pyrexia and mild infection of the umbilical wound. The baby took food normally within a few hours of the operation and showed no sign of peritonism or other untoward intra-abdominal disturbance and on the second day after operation a normal motion was passed

Follow-up—The baby was brought for inspection a month after the operation and again three months afterwards *He is in excellent health and thriving*

Pathology—The operation specimen consisted of a disc shaped tumour $^{7}/_{8}$ in in diameter and $^{3}/_{8}$ in. thick, connected to a stalk containing a central duct On section the tumour and duct were found to be lined with mucosa forming villi covered with columnar epithelium and goblet cells, as seen in the small intestine Gastric or colonic mucosa was not seen At the side of the duct was a fibrous cord, probably the obliterated vitelline artery

SUMMARY

A case of patent vitello intestinal duct complicated by prolapse of the intestinal mucosa through the umbilicus, is described.

The child s uneventful recovery after operation suggests that it is best to leave such cases for six months or more before operating Early interference is probably responsible for the high mortality rate in recorded cases (87%)

The obliterated vitelline artery is a potential cause of strangulation, which may necessitate earlier operation

Our thanks are due to Dr G Behr for his pathological report and the photographs, and to Dr J Grieve for the radiological reports.

TRAUMATIC RUPTURE OF THE BILE-DUCTS

J H. MILNES WALKER
M.B. Lond., F R.C.S., M.R C.P
SURGEON TO CREWE AND DISTRICT MEMORIAL HOSPITAL

RUPTURE of some part of the biliary tract is a rare *complication of trauma to the right upper quadrant of* the abdomen Injury to the ducts is less common than to the gall bladder : Rudberg (1921) described a case of injury to the common duct and collected 40 other examples of bile duct injury Lewis (1938) recounting a further case, could only find 6 additional ones since Rudberg s paper Since then 2 more have been reported complete rupture of the common duct (Lysaght 1939) and injury to the common duct associated with tran section of the pyloric part of the stomach (Grimault 1947) Of 54 cases of benign extrahepatic biliary obstruc tion recently described by O Malley et al. (1951) 46 followed some operation on the biliary tract, but not one was the result of non-surgical trauma

CASE REPORT

A farmer s son, aged 22 months, was admitted to Crewe and District Hospital on Feb 24 1952 having that morning been knocked down by a farm tractor a wheel of which passed over his body He had been unconscious for a short time but this phase had quickly passed and he was less shocked than would have been expected. His face, neck, and upper chest were covered with the minute petechiæ of traumatic asphyxia, and there were conjunctival ecchymoses. These signs and slight bruising over the back of the shoulders pointed to a crushing injury of the chest and neither symptoms nor signs suggested an intra abdominal injury. Radiological examination of the chest, pelvis, and skull was negative, and the child at no time showed evidence of any pulmonary affection His condition gradually improved, and by the ninth day the petechiæ had faded Slight conjunctival icterus was then noted On March 5, having been up for a day or two, he was allowed home

That night he came crying into his parents' bedroom It seems likely that he leaned against the side of his cot and fell out on to the floor From that moment his condition changed for the worse, and on March 8 he was brought back to hospital ill, lethargic, and with a distended abdomen Three days later he was jaundiced, his stools were pale, and there was evidence of free fluid in the abdomen Six ounces of turbid bile coloured fluid was obtained by paracentesis, this contained red blood cells as well as bile pigments The boy's condition was complicated by an attack of chickenpox During the latter part of March paracentesis was done three times, 42 oz being obtained on the last occasion Intraperitoneal rupture of a bile duct was diagnosed, the long interval before the occurrence of effusion suggested this rather than rupture of the gall-bladder

Operation (April 4) —A subcostal incision allowed the escape of bile from the peritoneum Separation of omental adhesions below the liver exposed a cavity whose walls were stained intensely green, as, to a lesser degree, were all the abdominal contents Within this cavity bile was issuing from a minute orifice at the porta hepatis A fine probe passed only 8 mm up this sinus, and its exact relationship to the ducts could not be determined, but it was near the junction of the right and left hepatic ducts The gall-bladder, cystic duct, and structures in front of the foramen of Winslow appeared normal Dissection amidst the bile soaked tissues around the orifice was impracticable A short length of 'Polythene' tubing was stitched to the margin and implanted into a loop of jejunum, which was fixed to tissues round the porta hepatis. A side-to side anastomosis between the limbs of the loop was made, and the abdomen was closed with drainage

Recovery —The child stood the operation well, and two days later he passed a normally coloured stool There was little drainage from the abdomen, which, however, remained for some days rather distended Subsequent improvement was rapid A month later cholecystography showed the tube in place but no filling by the dye Recent cholecystography shows similar appearances. In April, 1953, the boy was well and free from symptoms

ÆTIOLOGY

Injury to the bile ducts from external violence is always the result of a blow or crush in the region of the right costal margin Usually this is the only injury, but sometimes there is associated visceral damage Probably the direction of the force rather than its violence determines whether the ducts are injured, Lewis (1938) suggests that the force must be applied in a direction that will crush the ducts between the liver and vertebral bodies

In most case histories in which injury to the bile ducts has been the sole lesion there has been shock of short duration, accompanied by pain in the region of the liver The severity of these initial symptoms varies After an interval, which may be only a day but is usually longer and may be up to a fortnight or even more, jaundice, clay-coloured stools, and bile in the urine are observed, and the abdomen becomes distended This syndrome of jaundice with clay-coloured stools and rapidly increasing fluid in the peritoneum, which aspiration shows to be bile, is pathognomonic of injury to some part of the biliary tract Exhaustion, fever, and loss of weight become apparent, and the patient may soon become critically ill. The extravasated bile may be shut off by adhesions, and a limited swelling in the region of the liver, sometimes described as cyst-like, may be detected Sometimes the accumulation is limited to the lesser sac

In the present case the original extravasation was presumably shut off and became localised to a small cavity in the greater sac below the liver Subsequently, when the child fell from his cot eleven days after the accident, this ruptured, and escaping bile began to fill the general peritoneal cavity A case described by Edington (1933) provides an interesting parallel. Pain and jaundice followed a blow in the hepatic region, but diminished during the third week, and the patient returned to work On the twenty-fifth day, while boarding a tram, he strained himself, his symptoms recurred and subsequent operation revealed an extension of a previously localised extravasation to a much wider area There is an analogy here to the sequence of events in the delayed type of rupture of the spleen

It would be expected that some cases would develop a stricture, and this sometimes happens, though less frequently than after surgical damage to the ducts Perhaps the rent is usually small and involves only a portion of the lumen A stricture of a hepatic duct provides a most difficult problem, and the possibility of this sequel should be an important consideration in deciding the appropriate operation in the early stage Later it may be impossible to expose a strictured duct because of adhesions

PROGNOSIS AND TREATMENT

The *older records show* a high case mortality Aspiration, often repeated many times, was the usual procedure Every case described in the last thirty years has been treated surgically, in most cases bile has been evacuated and external drainage provided I have found no record in which direct repair of a torn duct has been satisfactorily accomplished without subsequent stricture Garré (1908) reported a case in which suture of a hepatic duct apparently succeeded, but a further operation was required a year later for cicatricial contracture at the site of anastomosis In Lysaght's (1939) case complete rupture of the common bile duct was associated with a rent in the duodenum, and retraction rendered repair impossible, he considered that ligation of the duct and cholecystogastrostomy would be simpler than implantation of the upper end into the stomach, duodenum, or jejunum, and this he successfully accomplished Several cases have required more than one operation, one, comparable to mine, of a boy crushed by the wheel of a car, described by Waugh (191 required three operations for drainage, in Edington's case, previously mentioned, thirty-three days after the first operation the biliary fistula was implanted into the stomach, and in other cases the development of a stricture has necessitated intervention after long intervals

It should be an important object of treatment to establish a flow of bile into the intestinal tract as soon as possible Exhaustion and wasting are the inevitable result of continuing loss of all or most of the bile from the body Patients with external biliary fistula improve when the bile is collected and returned to digestive through a Ryle's tube Every effort should be made to ensure that one operation will suffice, subsequent intervention is likely to be difficult and, as in Lewis's (1938) case, adhesions may render it quite impossible to identify important structures In rupture of the common duct ligation of the divided ends and anastomosis of the gall-bladder to the jejunum will usually be the most satisfactory operation Injury to the hepatic ducts presents a more difficult problem Damage is said to occur most frequently near the junction of the right and left hepatic ducts, but it has usually proved impossible to identify the individual ducts or the exact anatomical site of the rupture All that is seen is a little opening from which bile trickles An attempt should be made to provide a channel by which bile can flow into the intestine anastomosis of the fistula to a loop of jejunum succeeded in the present case and appears to be a suitable method o adopt in similar circumstances If this is impossible xternal drainage must be provided with the intention t a later date of implanting the fistula into the limentary tract.

SUMMARY

A case is described of traumatic rupture of the hepatic ucts in a child, treated by choledochojejunostomy

The ætiology clinical findings and surgical treatment re discussed

HAM GREEN HOSPITAL, BRISTOL

WHEN Lassen (1953) demonstrated in Copenhagen last ear that positive-pressure respiration combined with racheotomy could save life in certain types of polio nyelitis, it was obvious that treatment of this sort hould be available in this country

Lasson's original method required manual operation of the espirator and an almost indefinite upply of trained personnel The dvantages of an automatic type positive pressure apparatus was vident in Denmark, and Bang 1953) published details of such machine. It is understood that utomatic respirators have now een used in Denmark with arying success In this country Pask (1953) Beaver (1953) and Russell and Schuster (1953) have developed similar equipment. In April of this year we acquired or this hospital a manual respirator such as was used in Denmark, and later added the Oxford inflator described by Macintosh (1953)

Since it seemed very difficult o provide sufficient personnel to perate manual respirators in any umber we constructed an automatic respirator similar to that lescribed by Bang Although Bang described the principles of the apparatus, the engineering details were not defined. With the financial approval of the South Western Regional Hospital Board and the expert assistance of Mr M. J Willcocks of Willcocks (Clevedon) Ltd., Instruments Section, a prototype was produced. Improved patterns were available by the middle of July 1953 We now offer a preliminary report

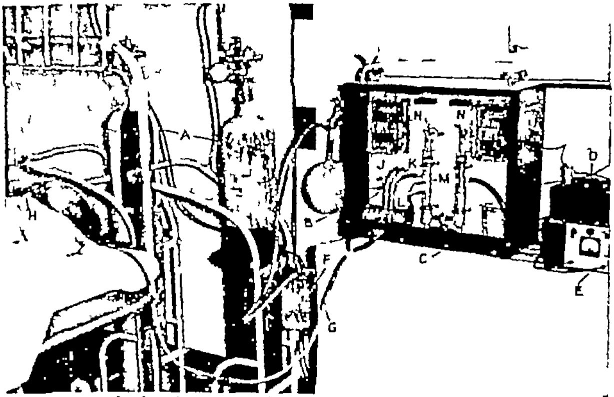
APPARATUS

The characteristics of the apparatus are evident in the accompanying figure It consists of a slide-valve operated by electromagnets which in turn are actuated by electrolytic switches in a U tube partly filled with acidified sodium-sulphate solution The machine is powered by a 12V battery delivering 1 amp maintained by a trickle charger The Clevedon machine is similar to that designed by Bang but the valve gear is original and electrolyte is used instead of floats in the U tube.

Medical air (British Oxygen Co) enriched with oxygen is supplied from large cylinders through a humidifier to a reservoir bag (an ordinary football bladder) and so through the inlet valve of the machine to the patient in a circuit closed by the tracheal tube cuff The pulmonary pressure built up by the inspired air pushes the electrolyte fluid up to the second switch, which opens the expiratory valve thus releasing expired air to the atmosphere The electrolyte falls under gravity to reach the original switch and so opens the inspiratory valve for another cycle The amount of air-oxygen mixture the speed the depth and the inspiration/expiration ratio of respiration can all be controlled The machine is of self-demand type and has an automatic safety valve There is only one moving part, and the valve mechanism can be changed in less than 30 seconds without undoing any nuts or bolts. Relays are used to reduce the current passed by the electrolyte to about 30 mA thus minimising electrolysis and sparking The apparatus is relatively cheap (about £60) is portable, and can operate independently of a main electricity supply

THE MACHINE IN USE

A well-developed man, aged 21 was admitted at 6.30 A.M on Sept 28 1953 with severe poliomyelitis. At 7.30 A.M. he was placed in a Drinker type tank respirator because of partial failure of his respiratory



The apparatus: A, air and oxygen cylinders; B reservoir bag; C, automatic respirator; D battery; E trickle charger; F humidifier; G gas tube to patient; H tracheotomy tube; J gas inlet; K, gas exhaust; L, valve gear; M electrolytic switches in U-tube; N electrical relays.

muscles During the day his paralysis spread, and by 6 P M the respiratory-muscle paralysis was almost complete In addition he had developed bulbar involvement, with inability to swallow, and was accumulating pharyngeal mucus Continued treatment in the tank respirator was obviously going to prove rapidly fatal, since it was impossible to keep the airway clear It was decided to try the positive pressure machine

The patient was transferred to a bed, and respiration was maintained with the manually operated Oxford inflator through a face mask Tracheotomy under local anæsthesia was performed by one of us (J M), a small window being cut in the trachea and a cuffed endotracheal tube inserted This was connected to the automatic respirator and satisfactory breathing was established at once Maximum comfort was obtained with a mixture of 4 litres of air and 2 litres of oxygen a minute at a respiratory rate of 12 breaths a minute The inspiration pressure was 16–20 cm H_2O. With this régime good air entry could be heard throughout all areas of both lung fields The success of the respirator was best shown by the fact that the patient fell asleep for the first time in two days

Nursing was carried out at a postural tilt of about 20°, head down From the beginning there was completely adequate aeration of the lungs

This automatic respirator has maintained the patient's life up to the time of writing, and minor adjustments only have been required For long periods the respirator has worked without attention The patient has been comfortable and cheerful and has had adequate sleep Heavy sedation has not been required Œsophageal tube-feeding was instituted on the second day General nursing, postural treatment, and catheterisation were all easily achieved and found to be a welcome change from the performance of similar tasks in the tank respirator The patient started to recover his ability to swallow on the sixth day, and œsophageal tube-feeding is no longer necessary On the twelfth day some spontaneous respiration recommenced, and now (Oct 27) the patient is able to breathe himself for periods of an hour

Secretions accumulate in the tube and suction of the tube has been necessary at intervals of two to six hours It has only occasionally been necessary to suck out the main bronchi The indications for suction seem to be simply the sound of râles in the tube audible at the bedside or conducted to the lung fields and heard through a stethoscope There have been no signs of fluid accumulating in the smaller bronchi or alveoli The endotracheal tube has been changed about daily

Although the difficulties of management have been considerably less than anticipated, there has been a doctor present in the ward at all times, and we feel that this is essential for safe supervision

SUMMARY

A positive pressure respirator which has only one moving part and works independently of a main electricity supply is presented

A case in which it is still being used is described

Our sincere thanks are due to Mr M J Willcocks and his many colleagues for the generous help and beautiful engineering technique which they have put at our disposal in producing this machine

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE association's annual meeting was held at Birmingham on Oct 23 and 24 SIR REGINALD WATSON-JONES was in the chair on the first day, and on the second day he was succeeded by the new president, Prof BRYAN MCFARLAND

For the first time in the association's history an instructional course in orthopædic surgery was given on the day before the meeting This course was attended by nearly two hundred young surgeons and senior orthopædic registrars, as well as by some of the fellows and members of the association

Presidential Address

SIR REGINALD WATSON-JONES, the retiring president said that the association had created strong ties between the orthopædic surgeons of Great Britain, the Commonwealth countries, and the U S A, it had given strong support to the foundation of the New Zealand Orthopædic Association and the South African Orthopædic Association, and with equal generosity from the United States and Canada had secured the foundation of travelling fellowships for young orthopædic surgeons between the United States, Canada, and Britain, with a share by other countries of the Commonwealth

The association, mindful of the value of tradition, had recently taken steps to stimulate interest in historical treasures relating to orthopædic and allied subjects. A collection of such treasures was to be housed at the Royal College of Surgeons of England, where a selection would always be on view in the college hall

Acrylic Replacement in Fractures of Femur

Mr DAVID LE VAY described his experiences with replacement arthroplasty of the hip by a prosthesis of the Judet type as the primary treatment of subcapital fractures of the neck of the femur The method was well justified in the elderly Most patients had been allowed up 4–5 weeks after the operation, and the average length of stay in hospital was 10 weeks Although there had been a tendency for the head to migrate into a varus position a point of stability was reached beyond which no further displacement occurred Insertion of the prosthesis to lie in slight valgus offered advantages

Mr O J VAUGHAN JACKSON, who had done replacement arthroplasty in 34 cases, suggested that it was still too early finally to assess its merits At best it did not give a normal joint, which was not true of a successful nailing operation it could therefore not be recommended for all patients with femoral neck fractures—certainly not for those in their fifties or sixties Of his 34 cases, the operation was tolerated well in 32 and poorly in 1, 1 patient died The main local complication was fracture of the prosthesis (4 cases), the use of metal prostheses in place of plastic would probably solve the problem of breakage Walking was resumed 5–6 weeks after operation Most patients preferred to use sticks for at least 6 months but none complained of severe pain

Mr G N GOLDEN (Guildford) reported 60 cases of Judet arthroplasty for fracture which he had reviewed in collaboration with Mr C C M Murray (Southsea) and Mr A. G Ord (Portsmouth) The results were good in 70% and satisfactory in a further 15%

The Valgus Foot

Mr G K ROSE (Shrewsbury) said that the dividing line between the normal and the "valgus" or "pronated" foot was ill defined, and the indications for treatment indefinite. He had undertaken a long term investigation of the feet of 1 children aged 6–8 years His conclusions were that some valgus shift was normal, but that there was no difference in the valgus index between boys and girls The significance of valgus shift was greatest when the axis of the knee was medial to that of the foot and least when the axis of the knee was lateral to that of the foot The essential pathological feature in the abnormal valgus foot was strain of the peritalar joint, not simply an abnormal position of the joint

Causes of Coccydynia

Mr H. J Richards (Oswestry) reviewed the possible causes f coccydynia in the light of a study of 102 cases. A history f injury was present in less than half the cases. Infection nd neoplasm were occasional causes; psychogenic factors ere secondary rather than primary He believed that in any cases coccydynia was caused by a central prolapse of ne of the lower lumbar intervertebral discs. Of 1000 patients iagnosed as having a disc protrusion, 40 complained of occydynia associated with sciatic pain; of the patients with occydynia nearly half had initial low backache or sciatica, nd most of the remainder later developed similar symptoms.

Mr K. I. Nissen expressed strong disagreement with Mr Richards's hypothesis. In his experience relief from coccy ynia could nearly always be assured by repeated manipulation f the coccyx: excision might be necessary in 5–10% of cases

Fractures of Lateral Condyle of Humerus

Mr J N Wilson (Cardiff) reviewed 57 fractures of the ateral condyle of the humerus in children. He recognised hree types (1) the flake fracture in which a thin piece of one was detached from the bony nucleus of the capitulum; 2) the type in which a large fragment was avulsed; and 3) the fracture with subluxation of the elbow joint. The ollowing complications were observed limitation of move ent (uncommon); deformity; ulnar neuritis; non union 1 case); and loose body In treatment, conservative methods ere usually successful

Professor McFarland advocated a cautious attitude owards the immobilisation of injured elbows in plaster

Treatment of Peripheral Arterial Disease

Prof. F A. R. Stammers (Birmingham) said that the vascular conditions that might be benefited by sympathectomy could be classified under five headings: (1) those from spasm (impaired circulation after poliomyelitis, acrocyanosis frigida, Raynaud's disease); (2) those from such anatomical abnormalities as cervical rib; (3) those from disease of the arterial wall with superimposed spasm of various degree (Buerger's disease, endarteritis, medial sclerosis atherosclerosis); (4) conditions caused by embolism; and (5) conditions caused by injury In the treatment of peripheral circulatory impairment the first aim was to remove spasm and promote collateral circulation Smoking should be absolutely prohibited (not just reduced) but alcohol was beneficial. Reflex vasodilatation by general body heating was a useful method of treatment Buerger's exercises and antispasmodics were worth a trial Operation should be considered when conservative measures were ineffective In general lumbar sympathectomy was more successful and more permanently effective than cervical sympathectomy In the treatment of intermittent claudication severance of the tendo calcaneus was of use only in the elderly it converted a painful hobble to a painless shuffle.

Muscle "Spasm" in Poliomyelitis

Mr G P Mitchell (Oxford) said that in his experience of the early stages of poliomyelitis there was no true spasm except in the spinal muscles during the stage of meningeal irritation. In the limbs, limitation of passive movement was the consequence not of true spasm but of the resistance of muscles to stretch The movements that were most restricted were those that caused traction on the main limb nerves, and if the liability to traction was increased by changes of posture—such as lateral flexion of the neck to the opposite side in cases of restricted elbow extension—the resistance to stretch was increased. Muscle resistance to stretch was simply a guarding reaction to prevent traction on the limb nerves.

Prof J Trueta (Oxford) considered that these observations solved the hitherto baffling problems of so-called muscle spasm in poliomyelitis.

Congenital Dislocation of Hip

Mr E W Somerville (Oxford) believed that in congenital dislocation of the hip the main factor responsible for the initial subluxation (which later progressed to complete dislocation) was anteversion of the femoral neck in consequence of which the femoral head exerted pressure on the anterior part of the capsule when the limbs were extended after birth. (Pressure was minimal while the limbs remained flexed so that dislocation before birth was unlikely) If the capsule stretched under this pressure the femoral head was extruded from the front of the joint and lay at first antero superiorly on the ilium. There it was so placed that the trochanteric region, by pressing upon the fibrocartilaginous limbus of the acetabulum, turned it over into the joint where it occupied the supero posterior part of the cavity and formed the chief obstacle to complete reduction of the dislocation by manipulation In every patient operated on he had found the limbus inverted as described, and he had produced an identical inversion of the limbus experimentally in a cadaver His plan of treatment—which was still on trial and was not yet advocated for general use—was to remove the inverted limbus, thereby allowing complete reduction of the dislocation and subsequently to do a rotation osteotomy of the femur to correct the anteversion and thereby prevent recurrence of the dislocation. The stage of unrestricted walking was reached within four months of the beginning of treatment So far, the results were promising

Mr H. J Seddon could not readily accept the hypothesis that the limbus played such an important part He preferred to rely on conservative treatment so far as possible; operation should be reserved for cases that were unsuitable for conservative treatment

Mr G C Gordon (Keswick) recalled that joints were formed at the 8th week of intra uterine development. He showed radiographs of a congenitally dislocated hip in a fœtus at the 28th week of gestation.

Isoniazid in Skeletal Tuberculosis

Mr A. G Quinlan (Oswestry) reviewed the results of isoniazid therapy continued for 6 months in 20 cases of skeletal tuberculosis. The drug distinctly improved the patient's general condition, but had no dramatic effect upon the tuberculous lesion.

Dr F Harwood Stevenson (Stanmore) suggested that streptomycin, *p*-aminosalicylic acid (P.A.S.) and isoniazid should always be used together to minimise the development of bacterial resistance

Mr M. B Devas reported that 10 patients with skeletal tuberculosis who had received a combination of streptomycin P.A.S., and isoniazid for 6 months all tolerated the drugs well, and in all cases the lesion was quiescent a year later

Foot Supports

Mr Norman Capener (Exeter) said that the association's subcommittee formed to study surgical appliances and splints was anxious about the promiscuous dispensing of foot supports "over the counter" When these were required for feet that were structurally abnormal, they should be made individually from plaster casts of the feet. When the feet were structurally within normal limits, he doubted the wisdom of prescribing foot supports at all.

Scoliosis

Mr F G Allan (Birmingham) described a new method of correcting scoliotic curves. In principle, the method consisted in the use of an extensible jack operated by a screw mechanism. Each end of the jack was designed to fit into the side of a vertebral body at its junction with the transverse process. The jack was so placed that it bridged the primary curve on its concave side. When in position it was extended by screwing the centre-piece with a tommy bar thereby reducing the curve Later a segment of the spine was fused by bone grafts. The method had the advantages that no plaster fixation was needed before or after operation, and that the time occupied by treatment was much reduced compared with correction by hinged plaster jackets. Moreover it had been possible to correct curves that looked incorrectible by ordinary methods. The operation had proved easiest in cases of lumbar and thoracolumbar curves. It was relatively difficult in thoracic deformity but the only complication of note had been pneumothorax from perforation of the pleura.

Mr H Osmond Clarke welcomed the report as a likely step towards the solution of the problem of scoliosis, especially in younger children in whom the recognised methods of treatment were notoriously unreliable

Primary Dislocation of Patella

Mr J S Ellis (Southampton) believed that primary lateral dislocation of the patella was commoner than was generally realised. It might explain some cases in which full function was restored after excision of a normal cartilage when the symptoms had been attributed erroneously to a torn cartilage Only occasionally did the dislocation persist usually spontaneous reduction occurred, and the diagnosis was then difficult The history might be like that of a case of torn medial cartilage; but there was hæmarthrosis (unusual with torn cartilage) and the tenderness, although on the medial side, was not localised to the level of the joint line A diagnostic sign was the pain produced by attempts to push the patella laterally At operation a rent in the capsule medial to the patella was to be expected When the condition was recognised soon after the injury operative repair, with pleating of the medial part of the capsule, should be considered

Dorsal Adduction Deformities of Fifth Toe

Mr W H Scrase (Birmingham) said that, in the treatment of dorsal adduction deformities of the fifth toe, manipulation and splintage were time consuming and seldom gave more than temporary benefit Amputation was often unacceptable to the patient, and it might predispose to tenderness over the fifth metatarsal head The technique described by Lapidus, which combined capsulotomy with transfer of the long extensor tendon to the plantar aspect of the phalanx, seemed attractive but he had little experience of it The method of skin advancement by V-Y plasty was said to be successful, but he had seen cases in which the deformity had recurred The operation that he had used was "syndactilisation" of the fifth to the fourth toe The extensor tendon was divided and the base of the proximal phalanx of the fifth toe was excised, the adjacent surfaces of the fourth and fifth toes were united after excision of a fillet of skin The results were good in 39 and fair in 3 of the 42 toes operated on

Mr J N Wilson (Cardiff) defended the operation of skin advancement by V-Y-plasty Professor McFarland claimed a long experience of the "syndactilisation" operation, which he had found satisfactory

Paralytic Dislocation of Hip

Mr G Blundell Jones (Exeter) described 12 cases of paralytic dislocation of the hip, in 7 of which this was bilateral The causes were spastic hemiplegia or paraplegia, poliomyelitis, and meningomyelocele In all of these patients the onset had been before the age of 2 years Mr Blundell Jones believed that the factor mainly responsible for the dislocation was an abnormal valgus position of the neck of the femur, which was often almost in line with the shaft Adductor contracture was a contributory cause After dislocation the acetabulum gradually became more shallow, but it retained useful depth for several years In the early stages the dislocation could be reduced by simple traction and abduction of the limb, but it was likely to recur Later, secondary contractures prevented reduction When the dislocation was reducible the hip had been made stable by wedge osteotomy at the base of the neck with restoration of the neck shaft angle to 120° The fragments had usually been fixed after osteotomy by a small nail plate

Mr Le Vay preferred to treat dislocations of this type by a shelf operation, which obviated shortening, preserved the efficiency of the abductor muscles, and did not endanger the blood supply of the femoral head But Mr Blundell Jones did not accept these arguments He had found the wedge osteotomy an easy operation, whereas it was difficult to construct a satisfactory shelf in the correct position He had not found that osteotomy at the base of the neck endangered the blood-supply of the femoral head

---

Reviews of Books

The Gold-Headed Cane

7th ed William Macmichael, M.D Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1953 Pp 222 47*s* 6*d*

This is an American reprint of the fifth edition which was published in 1923 The choice of edition is wise, for George Peachey's introduction and biographical notes enrich William Macmichael's text

Macmichael was registrar at the Royal College of Physicians of London when Matthew Baillie's widow presented the cane, a short time before the opening of the present building in 1825 The book takes the form of an autobiography of the cane, which was owned successively by John Radcliffe, Richard Mead, Anthony Askew, William and David Pitcairn, and Matthew Baillie The cane moved in the highest medical circles for a period of 130 years—from a few months after the accession of William and Mary to the middle of the reign of George IV—and it records engagingly the changing pageant of medical practice, besides giving interesting accounts of the foundation and history of the Royal College of Physicians and of the Royal Society

Somewhat oddly, in this reprint the picture of the original cane has been replaced by a plate of a gold-headed cane of different pattern presented to the outstanding medical student of the year at the University of California But we must be grateful to Prof W J Kerr, the new editor, for bringing a delightful book to the notice of a new generation of medical men and students

Pathology in Surgery

Edwin F Hirsch, PH D, M.D, director of the Henry Baird Favill Laboratory and pathologist of St Luke's Hospital, Chicago, Ill Baltimore Williams & Wilkins London Baillière, Tindall, & Cox 1953 Pp 647 76*s* 6*d*

Dr Hirsch's book is essentially pictorial for the text is concise and at times rather too elementary It could be used with advantage by senior students on those occasions when speedy revision of the subject of surgical pathology is unavoidable There are references at the end of each chapter, but they are few and hardly representative The eight coloured pictures are very good and the photomicrographs clear and helpful The reproductions of the gross specimens, however are occasionally disappointing, though great care has been taken in the selection of material

Dr Hirsch has made good use of his own experience, and students will be grateful to him for drawing attention to possible pitfalls which await the unwary—as for instance, that endometriosis is liable to be mistaken for carcinoma of the rectum, and a syphilitic lesion of the cervix uteri for carcinoma.

Lewin's Field Theory in Social Science (London Tavistock Publications 1952 Pp 346 21*s*)—It is still too early to assess the value of Kurt Lewin's contribution to social theory His stimulating personality, his experimental flair, his challenge to the Freudian use of a historical approach to psychological dynamics, and the devotion of his pupils, made him a prominent figure in American psychology Of his writings available in English most have reported work that he and his pupils did while he was still in Germany The present volume, edited by Dorwin Cartwright, shows how productive were his years in the United States, not only in tackling practical problems (such as an earlier collection *Resolving Social Conflicts*, described more fully) but also in developing his theoretical position Papers on the philosophy of science, written between 1940 and 1943, are followed by studies in learning, regression, social experiment, and group dynamics, the general outcome of his researches is presented in the final chapter Lewin's style in writing was dry, giving no hint of the attractiveness of his personal exposition of a problem. But the straightforward account of his views set out in this collection makes it plain that during the last seven years of his life he was an original and fertile influence on the development of social psychology

Diseases of Children (5th ed London Edward Arnold 1953 Pp 1973 £7) —In the six years that have passed since the last edition, much has happened that calls for notice in the revision of this splendid textbook, now edited by Prof Alan Moncrieff and Dr Philip Evans The sections that have been entirely rewritten include those on the causes of congenital malformations, on growth and development, on drug treatment, on kwashiorkor, on endocrine disorders, on diseases of the teeth and jaws, on the alimentary canal, on congenital heart disease, and on infant feeding As before, the book is in two volumes, but the page numbers now run on and there is only one index

Textbook of Medical Treatment (6th ed. Edinburgh and London E & S Livingstone 1953 Pp 1021 60*s*)—Reviewers have spoken so highly in the past of one of the most popular of textbooks that there is really no more to add to the observation that it is living up to its reputation. But we should perhaps note that the complete revision that has lately been made has introduced new chapters on chemotherapy, rehabilitation, the treatment of poisoning, and the chemotherapy of malignant disease, and the book has been reindexed to make the reader's way even smoother The editorial team is unchanged—Prof D M Dunlop, Prof L S P Davidson, and Sir John McNee

THE LANCET

LONDON SATURDAY NOV 7 1953

Winter Admissions to Hospital

EACH winter hospitals up and down the country ickle the recurring problem of finding beds for many xtra patients. Most of these have acute respiratory isease or heart-failure precipitated by bronchitis, nd sometimes their numbers are swollen by an nfluenza epidemic or other episode, such as last ear's catastrophic fog[1] The burden has usually allen mainly on the regional board hospitals—n other words the former local authority and maller voluntary hospitals—which perforce have ad to restrict surgical admissions, whereas in the eaching centres the impact of this additional work vas hardly felt at all. In 1951, however, the Emergency Bed Service introduced for the London rea a new warning system[2] for reducing, in times of tress, the number of non urgent admissions, and n this the teaching hospitals have participated to a arying extent. This system depends on the proortion of patients, referred by practitioners, for hom admission is secured. In the summer the E.B.S normally secures admission for about 90% f cases, the remaining 10% of applications being vithdrawn for one reason or another

> A *white* warning issued when the admission rate falls o 85% is intended as a preliminary alert.
>
> A *yellow* warning goes out with a fall in the admission ate to 80%; and on its receipt various steps may be aken to increase the number of available beds—includng, for example, the prohibition of closure of wards or cleaning a percentage reduction in cold surgery, nd reduction of admissions for investigation
>
> On receipt of a *red* warning, which goes out when the dmission rate falls to 75%, these measures are ntensified

Last winter, in its first real test this system proved its worth but some modifications have been necessary[3] since warnings tended to be issued too late and taken off too soon. There were two reasons for this defect Firstly as pressure on the service mounted, an increasing proportion of cases were admitted by the 'medical referee' procedure—which had the effect of keeping up the admission rate but of delaying the issue of warnings until the situation had become serious Secondly the response of hospitals to the yellow and red warnings caused a sharp rise in the admission rate and thus the warning might have to be cancelled even though applications were still increasing Henceforth for the purpose of warnings, cases admitted through the medical referee will not be included and warnings will not be cancelled until the 'voluntary-admission rate' (i.e excluding those arranged through the medical referee) has risen to 1% above the rate at which it was imposed and applications have fallen to the level at which they stood when the warning was issued Furthermore a white warning will be issued at the request of the Ministry of Health when it has evidence of an imminent emergency, such as an influenza epidemic

Possibly a better index of shortage could be obtained from a group of regional board hospitals than from the E.B.S figures Refusal of E.B.S cases is not necessarily a reliable index of bed occupancy Each regional board hospital receives from its own area many of the less "popular" cases including illness in the elderly and abortions, and if it opens its doors to similar cases from other parts of London it will soon have no room left for its other local commitments Thus refusal of E.B.S cases may not always be related to the immediate bed state.

In the past many hospitals have not appreciated the need for radical rearrangement to deal with winter epidemics Flexibility in the distribution of beds between surgeons and physicians is essential, and yet this distribution has remained remarkably rigid perhaps partly because of considerations of departmental prestige or the seniority of the various members of the medical staff Additional medical beds are an imperative need in the winter, and this seasonal addition could be offset by an excess of surgical beds in the summer months A further difficulty is that of ensuring a proper balance between the claims of semi urgent admissions and those of patients on the waiting list Some restriction of admissions from the waiting list is inevitable but patients whose condition is steadily deteriorating should not have their admission deferred for weeks on end as happened in some hospitals last winter To stop all admissions from the waiting list is not justifiable except for very brief periods It is invaluable to have a fairly senior member of the medical staff charged with the task of striking a balance between elective and emergency admissions Extra beds are no solution. In a winter epidemic, casualties among the nurses are often numerous, and overloading a hard pressed staff simply slows the turnover The most promising course is not to increase the number of beds, but to increase turnover by discharging patients more promptly This involves either securing closer liaison with general practitioners, as has been done at Cambridge,[4] or else making fuller use of convalescent homes. It is unfortunate that at present a convalescent home cannot be related to a particular hospital, for this would greatly aid the early transfer of patients In London much closer coördination is needed, too between outlying hospitals and those in the central area, last winter beds in peripheral hospitals were sometimes empty at a time when central hospitals had more to do than they could manage. The task of admissions officers would be made much less difficult by partial restoration of the arrangement whereby local authority hospitals were responsible for emergencies from a given district It would be wrong however to insist that all emergencies should be geographically distributed and indeed a greater number of acute cases could with advantage be admitted to the central London teaching hospitals (The regional medical admissions officer attached to the E B S represents only the four Metropolitan regional boards and has no authority to secure admissions to the teaching hospitals) It is particularly important that responsibility should be firmly imposed and accepted for the less "popular" group of cases

[3] *Ibid* Oct. 31 1953 p 934
[4] *Ibid*, 1951 i, 783

Now is the moment for every medical staff committee to review its arrangements in the light of last winter's experience, and to see that the hospital's resources are equated as closely as possible with the fluctuating needs of the population it serves

The Lethal Aerosol

WHILE public bodies debate the type of masks to be worn, and fashion designers plan fancy little yashmaks, the urgent question arises Can any sort of face covering, likely to be worn by the public, provide significant protection against the hazards of fog inhalation ? To answer this we need to know what the toxic agent is, how it is carried, and where it lodges in the respiratory tract There are several sources of information to which we can turn[1-8] Elaborate studies have been made in Los Angeles of the smoke-fog (the original "smog") so prevalent there[2], but this is rather different from our own polluted fogs, since it consists of smaller particles often in relatively dry air (25–30% relative humidity), the most noticeable effect of which is eye irritation Secondly, there is the Meuse disaster of 1930, when intense cold joined with fog and heavy pollution to produce a suffocative bronchitis, which killed 64 people[3] Investigators attributed the disaster to sulphur dioxide and its oxidation products in the air, and remarked that inflammatory changes in the lungs were slight and that adrenaline injections gave some relief Thirdly, at Donora, Pennsylvania, in 1948, there was again cold, fog, and serious pollution, leading to the death of many asthmatic or cardiac patients[4] Here it has been suggested that the deaths, which could not be ascribed to any single pollutant, were due to synergism between all the various contaminants It was noted, too, that the death-rate fell before the pollution began to lessen Fourthly comes London's experience last winter, when cold, fog, and an increase of sulphur dioxide and smoke in the air coincided, producing an enormous rise in mortality, particularly of elderly chronic bronchitics[5,6] RUSSELL's[7] careful statistical analyses of earlier London fogs had established a correlation between cold and fogginess on the one hand, and respiratory mortality on the other, and cold appeared to be the more important of the two factors All these accounts explain the general conditions that are likely to kill our bronchitics in winter-time, but they hardly supply the information necessary for effective preventive measures Until our fog has been properly analysed for particle distribution and constitution, we must proceed by intelligent guesswork

Fog consists mainly of watery droplets, 5–50 μ in diameter[1] Probably in such saturated air most of the enormous range of different kinds of nuclei (dusts, smokes, pollens, &c) normally carried in the air will have become centres of condensation, thus we shall be dealing principally with a gaseous phase in which watery droplets are suspended Secondly, if there is any water-soluble gaseous contaminant, such as sulphur dioxide, this will tend to dissolve in the droplets, so that the droplets will contain within them the bulk of the water-soluble material in the air This may be of fundamental importance Sulphur dioxide dispersed as one part per million throughout a gaseous phase might be relatively safe, but dissolved in droplets giving a local concentration thousands of times greater, it will produce a strongly acid respiratory rain, which may readily produce bronchial spasm and œdema Already, in fact, there are indications that, for the same total sulphur-dioxide content, a sulphur dioxide aerosol is more dangerous than the gas[9], and no doubt this would also be true of other pollutants Thirdly, droplets of this size will largely be retained in the respiratory tract—the largest in the nose, the smaller ones reaching the bronchioles Particles much smaller than this will tend to escape[10] We may therefore take it, as a working hypothesis, that the danger of these polluted fogs is due to inhalation in unusually cold inspired air of small droplets containing water-soluble pollutants in concentrated form, of such a size as to be retained in the respiratory tract and able to penetrate at least as far as the bronchi and bronchioles

Fortunately fog droplets are relatively large compared to bacteria and smokes A gauze mask or a woollen scarf could be expected to exclude a reasonable proportion—perhaps a half to three quarters—of the particles, which might be enough to bring the pollution of inhaled air below the margin of danger Complete purification is obviously too much to hope for The more layers of gauze used, the more efficient the mask will be, but a balance will have to be struck between efficiency and resistance to breathing The scarf or mask will serve a second purpose, warming and humidifying the incoming air Indeed, as the mask becomes sodden with expired condensation it may also come to serve as a watery "scrubber" of the gaseous phase, although at the same time its resistance will rise A gauze mask or, possibly better, a thick woollen scarf wrapped round the face, by excluding droplets and by warming and scrubbing the inhaled air, may, so far as can be judged, really prove useful The only obvious danger seems to be too great a respiratory resistance in a patient already breathing with difficulty Possibly, considering RUSSELL's analysis, warming the air is as important as filtering it A bronchitic's room should obviously be well heated, even if he cannot wear a mask, and, as CROWDEN points out,[11] the method of heating should not entail sucking in more fog from outside, electric radiators are particularly suitable

This discussion of therapeutic (as against preventive) measures can only be tentative, so long as the exact constitution of the fog and its lethal principle remains unknown There exists a rich store of experience from industrial and military research in making smokes and aerosols and in devising protection against them This experience should now be mobilised against an enemy long unchallenged

Dextran

Reports on the clinical use of dextran have shown hat the risk of reactions after its infusion is slight Iost of the reported reactions have been febrile, rticarial or allergic reactions have been few When, owever, dextran is injected into healthy people, he story is rather different As was first observed n America, nearly 50% of healthy recipients may how reactions of one kind or another and the incidence seems to be related to the type of dextran used On an earlier page Mr Wilkinson and Dr. Storey escribe the results of infusing 500–1000 ml of a olution of closely fractionated dextran into 5 normal olunteers with normal blood volumes All 5 showed eactions, which can be roughly divided into two hases The first which developed during or soon fter the infusion and lasted up to two hours, was redominantly urticarial, the second usually eveloped later and was characterised by vasomotor nstability Wilkinson finds that the later phase oincides with a decrease of the plasma volume below he pre-infusion level. This was observed in all the ubjects within about two and a half hours of ompleting the infusion and was accompanied by the movement out of the vessels of up to 30% of the total irculating albumin and dextran Thereafter dextran e-entered the circulation, and the total circulatory protein was greater than before the injection, the plasma volume increased and remained above the pre-infusion level for many hours During this last eriod the volunteers complained of fullness of the ead, precordial pain, and breathlessness on exertion Wilkinson has given the same solution of dextran o "shocked" patients (he does not say how many) with only 2 mild and transient reactions

Heistø and Lund [1] have described a somewhat similar sequence in 20 normal people, each of whom was given an infusion of 1000 ml. of one of eight different batches of dextran, derived from different strains of *Leuconostoc mesenteroides* and prepared by acid hydrolysis or thermal or ultrasonic degradation. Reactions broadly similar to those now described by Wilkinson were noted in 15 of the 20 subjects In 13 the reaction was accompanied by diminution of plasma volume (after an initial increase) below the original level and decrease of total circulatory protein. In non reactors and 2 of the reactors the plasma volume was increased during the five hour period of observation and there was no appreciable change in total circulatory protein Heistø and Lund found that the incidence of reactions was related to the strain of *L mesenteroides* used in preparing the dextran, but not apparently to the method of preparation Neill and Abrahams [2] have demonstrated cross-reactions between antisera to *Salmonella typhi* and other members of the salmonella group, and native and clinical dextrans and Heistø and Lund say that in their study the severity of reactions seemed to be related to the time which had elapsed since T.A.B inoculation. This however may have been fortuitous for the number given each type of dextran was small. In a larger American series [3] no relation could be found between the number and type of prophylactic inoculations and the incidence of reactions Like Wilkinson, Heistø and Lund found that their batches of dextran could be given without ill effect to patients with oligæmic shock.

Kabat and Berg [4] and Maurer [5] have investigated a large number of native and clinical dextrans and have shown that these, given in 1 mg doses subcutaneously to normal individuals, are antigenic, judging by the development of precipitins and cutaneous sensitivity of the weal and erythema type Precipitins and positive skin reactions were found in some of the volunteers before the dextran was injected, indicating that they had already been immunised by some means These workers conclude that the dextrans themselves were antigenic and that the antigenicity was not attributable to linkage to protein or some prosthetic group This antigenicity seemed to be related to the chemical structure of the dextrans, some of which evoked less antibody than others The numbers of subjects injected with each dextran were too small for conclusions on the relative antigenicity of each batch or on the proportion of normal people who are already sensitised. If, as Maurer suggests some people do not respond to dextran as an antigen the interpretation of the results is all the more difficult since the proportion of non reactors is unknown Kabat and Berg suggest that the urticarial or allergic reactions observed after injecting dextran in normal people, or in patients are probably caused by the presence of antibodies to dextran Maurer considers that antibodies to pneumococcal polysaccharides, types II, XII, or XX, which are known to give cross reactions with dextran, are probably not of great clinical significance, since he found that the anti dextran antibody nitrogen levels were much the same before and after absorption with these polysaccharides Neill et al [6] have shown that dextran is a common contaminant of commercial sugar, and Hehre and Neill [7] have isolated dextran producing organisms from the human intestine Kabat and Berg, and Maurer, suggest that in certain circumstances either or both of these factors may possibly provide an antigenic stimulus so that antibodies to dextran are formed

It seems clear that some people are sensitive to certain kinds of dextran, but the response to a small dose of antigen is not necessarily the same as that elicited by a large dose. Felton and Ottingen [8] have described a state of "immunological paralysis" with polysaccharide antigens In patients the response to an antigen may be altered by the disease or by anæsthesia. Dextran solutions of many kinds have been given to thousands of patients and it is most important to know whether any have become immunised So far as we know, there have been no reports on the effects of second infusions of dextran in patients, or of observations designed to show whether any patients given an infusion of dextran become sensitised and show the type of response described by Kabat and Berg and by Maurer. The lack of adverse reports may indicate that very few patients, or none, are sensitised by an infusion

of dextran This is supported by a series of observations on normal individuals in America [9] which showed that second infusions of dextran four to twenty-three months after the initial infusion were not followed by systemic reactions, except in those who had reacted to the first infusion, and in these the reactions to the second infusion were not more severe than the reactions to the first Furthermore, the incidence of positive reactions to the intracutaneous injection of dextran in people who had previously been given an infusion of dextran was the same as in persons who had never been given dextran This indicates that infusion of dextran had not given rise to true sensitivity

There is still much to be learnt about dextran Certain strains of *L mesenteroides* are poor antibody producers in animals, it would be worth investigating whether the corresponding dextrans are only weakly antigenic or even non-antigenic in man There is evidence that the antigenic response is influenced by the chemical structure of the dextran and possibly also by its molecular size, and varying the composition of the medium in which the organism is grown is known to affect the chemical structure of the dextran produced Further study of this aspect would seem worth while Furthermore, it would be valuable to secure agreed physical and chemical methods for characterising the many different dextrans, many reports give insufficient information for the dextran to be identified

In the last five years dextran has been investigated more intensively than probably any other plasma substitute, and the story, in unfolding, has gradually become more complex As examination of the other plasma substitutes progresses, a similarly involved picture is likely to develop Some of the new information about dextran merits careful thought, but the clinical evidence suggests that dextran solutions can be administered safely

Facts from General Practice

Two factors are helping to secure for general practice the prominence it has always deserved but which it was in danger of losing One is concern over the increasing cost of the hospital service and the tardy realisation that, if the general practitioner is to check this drain on national resources by himself investigating and treating illness in its early stages, he must receive both credit and help—including access to investigation departments The other factor is a new awareness that, in our preoccupation with hospital techniques, we have been neglecting first causes in the home and the place of work Had research into these causes been pursued as vigorously as that into the causes of infectious diseases, the total of our people's ills might now be less, and if this backwardness is to be ended we shall have to look largely to the general practitioner, who is better placed than most to study the influence of heredity and environment on health and disease in the individual and the family Here again he needs help, and he needs, too, the opportunity to coöperate with his fellows Fortunately, both are likely to be obtainable through the College of General Practitioners [10]

But if the family doctor is to make a serious incursion into this field, he must know the extent of morbidity in the population, and the contribution of each disease to the total—a subject on which we still have little precise information As a source of the essential knowledge the experience of general practitioners themselves is necessarily imperfect, but it is about the best we have at the moment A first attempt to tap this source is recorded in a report,[11] issued this week, in which Dr W P D LOGAN, chief medical statistician of the General Register Office, sets out the results of a year's experience (from April 1951) in eight widely different practices The eight practitioners recorded the date and place of consultations, certificates issued, referral to hospital or elsewhere, and diagnosis or other reason for consultation These data have yielded information which, though it may not apply to the country as a whole, goes some way to replace impressions by facts

Reasons for consultation.—The two diseases responsible for the largest proportions of consultations were acute nasopharyngitis (common cold) (60 9 consultations per 1000) and bronchitis (53 0 per 1000), additional to the latter were acute bronchitis (4 9) and chronic bronchitis (10 8), giving a total for bronchitis of all kinds of about 68 7 per 1000 Next came influenza (26 5) and acute tonsillitis (22 1) Other conditions that accounted for more than 10 consultations per 1000 total were asthma (10 5), asthenic reaction (neurasthenia, &c) (11 1), otitis media (19 7), hypertension (16 3), pneumonia (12 4), gastritis (11 9), functional gastric disorders (indigestion, &c) (14 1), gastro-enteritis (12 6), boil and carbuncle (15 6), dermatitis (10 2), muscular rheumatism (16 0), "rheumatism" (15 0), cough (11 4), and routine antenatal examinations (19 4)

Respiratory diseases accounted for 24 % of all consultations, digestive diseases for 9 %, diseases of the nervous system and sense organs for 8 %, circulatory, locomotor, and skin diseases for 7 % each, infectious diseases for 6 %, and injuries for 5 % Allergic and endocrine diseases and genito-urinary disease were each responsible for 4 %, the mental and psychoneurotic group for 3 %, and neoplasms, blood diseases, and maternal complications each for 1 % Symptoms and senility accounted for 8 %, and reasons other than sickness for 5 % of the total

Sex differences —Three out of every five consultations recorded were in respect of female patients, but, taking account of their larger numbers in the practice populations, this excess was only 25 %

Place of consultation —68 % of all consultations were surgery attendances, 27 % were home visits, and 5 % took place elsewhere

Certificates —The diseases that accounted for the largest proportions of certificates (including National Health Insurance, private, and other certificates) were:

	Proportion per 1000 total certificates	
	Male	*Female*
Psychoneurotic disorders	17 7	43 8
Acute nasopharyngitis	46 3	70·0
Acute tonsillitis	20 7	28·0
Influenza	80 9	54 1
Bronchitis	91 3	53 1
Ulcer of stomach and duodenum	40 6	11·6
Fibrositis	27 4	18 2
Maternity antenatal	—	35·4

Of all certificates issued 29 % were for respiratory disease—well over twice as many as for diseases of the digestive system, which were the next most common reason for issuing a certificate Certificates for non medical pur-

oses (e.g , countersigning of claims for family allow nces old age pensions and tobacco tokens) accounted or only 0 3% of all certificates issued

Referrals —The most frequent diagnoses for which atients were referred to hospital or elsewhere were

	Proportion per 1000 total referrals	
	Male	*Female*
sychoneurotic disorders	20 2	21 2
cute tonsillitis	28 1	27 2
ronchitis	63 3	33 1
lcer of stomach and duodenum	25·6	10·6
ppendicitis	20·5	23 3
isorders of menstruation	—	31 8
ractures	23 7	10 1
aternity antenatal	—	58 5

he conditions for which admission to hospital was most ften arranged were appendicitis and pneumonia.

Number of consultations.—The average number of onsultations during the year per patient on the doctors' ists was 3·4 for males and 4 2 for females.

From these and many other findings tabulated in he report Dr LOGAN concludes that simple data of he sort recorded by the eight practitioners are suitable or statistical analysis He admits that conscientious ecording was an additional burden on the doctors , ut the weight of this, he feels, was greatest at the tart, and he believes that such a system can be kept going without undue difficulty even during busy periods. " There can be little doubt," he says, that general practitioners' records " potentially constitute one of the most valuable sources of information on morbidity " The size and scope of the inquiry may eventually be increased but meanwhile it is being continued on the same lines for a second year Dr LOGAN adds two warnings One is that terminology and measurement throughout the whole field of morbidity statistics are still being developed, and the best methods of tabulation are undecided The other is that doctors who think of embarking on their own comprehensive analysis should recognise that this is likely to prove much more burdensome than the record keeping itself Even the General Register Office, with its large resources, seems to have been quite heavily taxed in analysing the data from this limited survey

This survey was designed to show what constitutes general practice But clearly a similar approach might throw much new light on the sources, extent and effects of morbidity It is a strange twist that has brought the family doctor who prides himself on dealing with individual people to his present position in which in league with a Hollerith machine he will be handling masses of figures Perhaps this first account will give him heart for the task

Annotations

MAN AND DISEASE

THE historical record of man's early steps towards the understanding and treatment of disease may often seem to the student a jumbled and unhelpful story that is of little use to him in absorbing present-day teaching But careful study and perceptive interpretation can pick out the threads from this tangled tale and turn it into a fascinating introduction to the more familiar events of recent years. And this is what Sir Henry Cohen did at the Royal Society of Medicine last week when, in his presidential address to the section of medicine he discussed the Evolution of the Concept of Disease

Primitive man was little concerned with the nature or cause of disease he concentrated on its cure Sir Henry pointed out how the earliest remedies were based on certain doctrines which though they were crude and supernatural, had profoundly influenced later thought. There was the doctrine of similars whereby for example, stewed raven was the cure for greying hair ; the doctrine of signatures which held that distinctive markings on a plant indicated its medicinal properties (thus, yellow celandine was the thing for jaundice) ; the doctrine of analogy which drew comparisons between the treatment of animals and of man ; and the doctrine of contagion which attributed a baleful influence to external forces and which led among other things, to the popularity of moonstone for mental illness. When it came to the appreciation of the nature of disease, two ideas had dominated man s thought since earliest times : disease as a separate entity quite distinct from the individual affected ; and disease as a deviation from normal These two views had coexisted until the present day sometimes overlapping sometimes one or the other predominating according to the philosophy of the time and the influence of outstanding personalities.

The most primitive form of the " entity idea was the explanation that disease was caused by a variety of evil spirits, which called for treatment by incantation burnt offering and sorcery These practices could still be recognised from time to time in modern life : the raw potato carried for the prevention of rheumatism was the equivalent of the primitive amulet and Sir Henry recalled a case in his own experience where the relatives of an Armenian patient had sacrificed a pigeon in the belief that they might thereby instil new life into the dying woman. The notion of diseases as separate entities developed from this demoniacal concept : and it was fostered by the careful descriptions of individual illnesses recorded by Hippocrates and later physicians They all dealt with particular cases, and no attempt at generalisation was made until the 9th century A.D when Rhazes of Persia differentiated between smallpox and measles. As many separate diseases became recognised the idea gained ground and it was given impetus in the 17th century by Linnaeus s *Systema Naturae* in which he observed that there are as many species as there are diverse forms that were created in the beginning ' and by Sydenham who declared that diseases were ' to be reduced to certain and determinate kinds, with the same exactness as we see it done by botanic writers in their treatises of plants." The entity point of view reached its peak perhaps when in 1763 François Boissier de Sauvages botanist and physician (botanist first it seems) grouped diseases into classes, orders genera, and species (of which there were 2400 in all) This conventional and rationalistic outlook of A (the patient) plus B (the disease) was still apparent Sir Henry thought, in much of our teaching today It was often responsible for a misguided dependence on pathognomonic physical signs and a fondness for the penny in the-slot diagnosis

The alternative view of disease as a deviation from normal had its roots in Greece whose philosophers sought to generalise from inadequate particulars and to conceive the whole of Nature without a sufficient knowledge of its parts They developed the idea of the four humours—blood, phlegm, yellow bile and black bile—that was to dominate medicine for 2000 years But it was before the humours were described that Plato first stressed the discord of disease, attributing it to abnormal quantity quality, or position of the four elements of the body Plato s views led to the school of thought whose followers Galen called the Dogmatists and who held the field for a century after the death of Hippocrates They were followed, in the 2nd and 3rd centuries B C, by the reactionary Empirics who, though they were mainly concerned with treatment, had the idea of a syndrome And a century or so later came the Methodists who simplified everything by classifying all diseases according to the state of the pores relaxed pores called for astringents and constricted pores for laxatives, so that treatment was very simple From these early beginnings the idea of deviation from normal had to await the development of anatomy and physiology before it made substantial progress, and things did not begin to move until the 16th and 17th centuries Physics and chemistry then began to play their part in disclosing the deviation from normal, and Sir Henry particularly emphasised the significant effect on medical thought of the synthesis of urea in 1828, which showed clearly and for the first time the relevance of chemistry to medicine The discoveries of the 19th century brought increasing knowledge of the normal and departures from it, but there was still the risk of interpreting such newly recognised conditions as hyperchlorhydria, hypertension, and polycythæmia as distinct entities

Turning to the present scene, Sir Henry declared that the concept of disease as a deviation from normal should dominate our teaching and our approach to medicine The constant patterns—the syndromes or symptom-complexes—in which symptoms and signs appeared always indicated one or more of three aspects of disease its site, the associated functional disturbances, and the causative factors Specific and common patterns could conveniently be regarded as entities, but there were dangers in giving too much scope to this view, which lulled the doctor into being satisfied with a label and reduced thought to a minimum Philosophic inquiry in medicine was apt to be regarded as an arduous eccentricity for which few physicians today had either the opportunity or the inclination But it was, Sir Henry concluded, a worthwhile pursuit, for it helped to keep a balance between our dogmatism on the one hand and our scepticism and discouragement on the other Above all, it inculcated humility in the presence of great minds which was the surest shield against intellectual arrogance

DEHYDRATION IN INFANTS

THE last few years have seen rapid developments in fluid and electrolyte therapy based on physiological principles established during the past three decades But treatment by fluid replacement is over a hundred years old, for the first reported cases were treated by Dr Latta during a cholera epidemic in Scotland in 1832 [1] Progress thereafter was slow, but, following the work of Marriott [2] on dehydration in infancy, fluid replacement speedily established itself as of outstanding importance in the treatment of many diseases—and especially those producing diarrhœa in infants At the annual meeting of the Australian Pædiatric Association earlier this year the present position of this method of treatment in infants was reviewed in four papers that have now been published Macdonald,[3] dealing with the physiological principles involved in the maintenance of the fluid and electrolyte balance in infancy, emphasises the importance of using the correct terminology in discussing electrolytes But, as Dr Ennis points out in our correspondence columns this week, many clinicians do not take kindly to the milli equivalent and prefer to stick to the familiar "milligrammes per 100 ml" They are reproved for their reluctance to move with the times by Professor Dods,[4] who pointed out at the Australian meeting that "it was only by talking and thinking in these terms of chemical equivalence that they could have any real concept of electrolyte patterns Without this concept of electrolyte anatomy, any discussion of the problem must necessarily be vague and nebulous"

The electrolyte pattern of the newborn infant differs from that of an adult in several ways [5] The potassium, chloride, sulphate, and phosphate content of the plasma is higher and the bicarbonate and protein levels are lower In the premature baby the bicarbonate level is even lower than in the full-term newborn, and the tendency to acidosis that is present in all newborn babies is more definite The control of acid-base equilibrium is often unstable and the regulating mechanism of the kidney is incompletely developed Campbell [5] points out that late tying of the cord may add from 3 to $3^{1}/_{2}$ ounces of blood to the baby's circulation, equivalent to giving a 10-stone adult a blood-transfusion of $3^{1}/_{2}$ pints She advocates delayed feeding of newborn infants, whether premature or full-term, principally in order to give the babies rest. Premature babies begin to look dehydrated at forty-eight hours and Campbell advises that the administration of fluids should begin then, especially if the infant is much jaundiced fluids should be given parenterally if the infant is not taking too well by mouth In her view the high serum-bilirubin, together with low blood glucose level, may be dangerous to brain tissue and is a possible cause of "premature kernicterus" [6,7] Williams,[8] discussing the management of dehydration in enterocolitis, also emphasises that assessment can be made largely on the clinical evidence and that biochemical tests are not essential in the early acute phase The Australian recommendations for treatment are similar to those given in the recent Medical Research Council memorandum on the treatment of acute dehydration in infancy [9] One important point is that potassium depletion is likely to occur if long-continued intravenous therapy is given without the administration of potassium [10]

Finally, Stuckey [11] deals with the surgical aspects of dehydration in infancy and childhood, with particular reference to high intestinal obstruction Dehydration in these patients is due partly to the abnormal losses of intestinal secretions by vomiting, aspiration, or fistulæ, and partly to the failure to take or retain normal amounts of fluids by mouth Treatment is planned in four phases The first step is resuscitation, either from surgical shock or from severe dehydration Stuckey favours blood or serum given fairly quickly, he does not mention plasma, which is more commonly used in this country If dehydration is severe the protein-containing fluid is followed up with glucose saline solution. The second phase is concerned with the correction of moderate dehydration over the next twenty-four hours with replacement fluids, in amounts equal to 6% of the body weight, followed by maintenance fluids, in amounts up to 15% of the body-weight daily Stuckey recommends that the replacement fluid should contain potassium as well as sodium, but some may question the routine use of potassium at this stage The third phase, starting on the second day of treatment, consists in making up any deficit and in maintaining fluid and electrolyte balance On the third and subsequent days the balance is maintained and protein or amino-acids are given Throughout a constant check is kept on all fluid losses so that the balance can be carefully regulated

The chief lesson seems to be that effective treatment, derived from sound physiological principles, can be given without recourse to expensive, and often unobtainable, biochemical assistance

THE BLIND IN OUR MIDST

AN increase in newly registered blind persons from 586 in 1948 to 11 155 in 1951 is revealed in a report y Prof Arnold Sorsby[1] The bulk of the new registra ons now come from the oldest age group ; but clearly e extension of welfare services, and greater readiness patients to seek certification and hence of doctors certify borderline cases have also played a part.

Cataract, glaucoma, and senile macular degeneration gether, now account for 50 7% of all cases of blindness 1950, as many as 80% of cataract patients are reported not having had treatment. This seems deplorable a time when advances in the technique of cataract traction have made the operation, in expert hands, fer and more widely applicable than in the past. he matter certainly calls for further inquiry The roblem of glaucoma is less tractable, principally because the insidious course of the disease in the ageing he disease may be halted in its early stages by timely peration and thus prompt detection is of the greatest nportance. The growing number of glaucoma clinics association with eye hospitals is a token of medical wareness of this problem. More such cases are likely come under medical care at an operable stage when e supplementary eye service is superseded by the ermanent service

FITNESS AND HEALTH

AT Leighton Park last Saturday Sir Russell Brain R C.P., opened a big new gymnasium which forms part f the school's war memorial What, he asked is the lation between fitness in the everyday sense of keeping t and fitness as the biologist uses the term when he peaks of survival of the fittest ? Fitness to survive epends on changes that give an organism increased ontrol over its environment but all creatures alive oday must have passed this survival test Man, the ger and the typhoid germ all equally come within the iological definition of fitness ; and though man may egard himself as of more value than a typhoid germ hat after all is only his prejudice

It is obvious, continued Sir Russell that health has layed and is still playing a major part in evolution : o be fit (in the full or ideal sense) is surely to be able to ake the best possible use of one's capacities, both hysical and mental—which in biological terms means eing as fully adapted as possible to one s environment. What then is health ? In its negative definition it is the bsence of disease But disease is itself a negative term neaning the absence of ease Can we then define health s the absence of the absence of ease ? To do this is ot only to go round in a circle but to make health and lisease look simpler than they really are. The *Nomen lature of Diseases* itemises 15,000 ways of being ill ; no loubt others are waiting to be discovered and the more e understand of these diseases the more complex we ind them In the case of many infections for example t is true to say that whether a person catches them or ot depends on a long chain of circumstances many of which are entirely outside his control There is not some ingle condition called health which has magic properties which make people immune to every kind of illness The prevention of disease depends first on knowledge and then usually on the coöperation of numbers of different people in different spheres of life—including of course the potential patient

"But I am afraid that the part the potential patient can play is, on the whole, rather limited, and what are sometimes called a few simple rules of health, however desirable they may be in themselves, and however they may promote a sense of well-being have on the whole very little to do with the prevention of the majority of diseases. It follows that anyone who propounds some simple way of maintaining health, and preventing all or a large number of diseases, receives no support from science "

Turning to health of mind, Sir Russell agreed that we live in one of those epochs when human culture suddenly undergoes a rapid change But stress of life is insepar able from living it is part of the evolutionary process Our problem is how to adapt ourselves to new ideas and modes of living and how to face emergencies which may threaten both our individual existence and our civilisa tion This is not a problem to which medicine, as such can give any answer The doctor may make the diag nosis but the stresses of modern life are part of the culture to which he himself belongs, and any possible way of dealing with them must reach out far beyond medicine and concern itself with a belief about ultimate things on which doctors differ as much as other people Offering what was therefore a personal rather than a medical view Sir Russell pointed out that happiness contributes to peace of mind and therefore to health of mind and health of body ; and on the whole the happiest people are those whose work is of such absorbing interest that for them there is no great distinction between work and play He believed too, that the nature of man is such that his happiness is closely related to the life of Nature and the cultivation of the soil : I suspect that in any society there is a certain critical balance between agriculture and industry, and when the balance is tipped too far in the direction of industry some virtue goes out of the society " And finally there is the spiritual isolation of modern man

> Cut off largely from the rhythms of the earth, from the natural ties of the small community from conscious communal efforts, and from the secular and religious festivals in which the individual and the community alike found expression and satisfaction for their deeper feelings, modern man experiences a spiritual hunger of the nature of which he may be hardly aware Perhaps one thing which made the Coronation ceremony so moving was that it momentarily satisfied this deep human need. Here I believe is the cardinal problem which modern society has to solve if men and women are to be able to cope with its inevitable stresses.

But the view of health as the absence of disease of body and mind is very incomplete : it is not enough not to be ill—even not to be ill in 15 000 ways We must make it our aim that everyone should have the best oppor tunities for the fullest possible development and use of both his body and his mind. This idea of positive health (sometimes claimed as a modern discovery) is, like the word gymnasium ' as old as Plato—who thought that one of the virtues of gymnastics was that it kept the doctor away though he admitted its impotence against what he called "an attack of illness incidental to the time of year ' In the gymnasium people learn endurance control, and (issuing from that) poise or balance and we know by experience, as Plato knew, that training in these bodily virtues develops them also in the mind.

Man is regarded as supreme among animals because his nervous system is by far the most complex reflecting the enormous range of his interests and activities and if it is argued that the tendency of evolution is to produce creatures which react to an ever wider and richer environ ment, then man represents the highest point so far reached. But can we assume asked Sir Russell, that contact with a complex environment is in itself a good thing ? The amœba might well defend the simple life ! To what environment, then is man required to adapt himself ? More and more people would now say that all there is for him to adapt himself to is the material world, as analysed measured and calculated by the scientists ; but future historians of thought may be surprised at the long acceptance of this materialist philosophy by so many intelligent people If the material world is all, there can be no basis for lasting values independent of material forms, but if it is not the whole story, at least the door is opened for exploration of a realm in which such values could exist One form of life or mode of living cannot be regarded as better than another unless values exist which transcend the laws which govern the behaviour of matter If so, as Walter de la Mare says

[1] The Causes of Blindness in England 1948–1950 Report by Prof. Arnold Sorsby H.M. Stationery Office. 2s

> "Two worlds have we, without, within,
> But all that sense can mete and span,
> Unless it confirmation win
> From heart and soul, is death to man."

This means, said Sir Russell, that health, valuable as it is, cannot have top priority it must often be sacrificed for some greater end, and some of the greatest servants of mankind have not only triumphed over illness but have somehow made their sufferings serve a higher purpose He ended his address by saying

> "Health, if you like, is a means to fitness, but fitness—for what? I leave that question with you as I declare open this gymnasium, dedicated to fitness of body and mind and to those spiritual values for which those whom it commemorates gave their lives"

HOSPITAL COSTING

THE Minister of Health has set up a working party to devise a practical system of departmental and unit costing in hospitals, on the basis that subjective accounting will be retained This action arises from consideration of the reports on costing by King Edward's Hospital Fund for London and the Nuffield Provincial Hospitals Trust,[1] and also the second report on costing of a subcommittee appointed by the Committee of Regional Hospital Board Treasurers Mr W O Chatterton is chairman of the working party, which includes representatives of the Ministry, the administrative and financial officers of hospital authorities, the King's Fund, and the Nuffield Trust The working party, which is being asked to complete its task, if possible, in six months, will be free to suggest different systems for different types and sizes of hospitals

COLD-STORAGE OF LIVING CELLS

Thomas Alva Edison is reported to have said "Invention is ten per cent inspiration and ninety per cent perspiration" This description is particularly appropriate to the invention of methods of preserving living cells in the frozen state The idea that animation might be suspended indefinitely has often inspired attempts to preserve cells at low temperatures Success was rare because of the particularly destructive effects of the act of freezing and because it was not realised that each type of cell required an individual technique of freezing It was discovered in 1949[2] that death on freezing could be avoided if the cells were suspended in a medium containing glycerol, and this removed at one stroke the main barrier opposing the preservation of living cells in the frozen state The importance of the discovery has been shown by the astonishingly rapid progress in the last four years, which was reviewed at the Royal Society of Medicine on Oct 27

The use of glycerol to preserve frozen yeasts, protozoa, red blood-cells, spermatozoa, and even organised endocrine tissue was surveyed by Dr Audrey U Smith Adverse effects, such as thermal shock and the differences between cells in their permeability to glycerol, make necessary individual techniques of freezing for each type of cell and tissue The mechanism of the protective action of glycerol appears to be clear cut and simple[3] According to Dr J E Lovelock the most serious and unavoidable source of damage on freezing is the rise in concentration of the electrolytes of the cell and its medium Glycerol prevents this excessive increase of salinity, which is otherwise unavoidable when water is removed as ice during freezing

Skin is a complex mixture of cellular types, and the development of a method of freezing and storage which harms none of them is a considerable achievement We have already commented[4] on the success of Billingham and Medawar[5] in storing rabbit skin without loss of function for one year at −78°C In describing this and other experiments on the preservation of skin, Prof P B Medawar, F R S, emphasised the singular lack of toxicity of glycerol Its effectiveness as a preservative must depend greatly on this property, for during freezing it displaces much of the water within the cell

The successful transfusion of human red blood-cells after long storage at −78°C is an accomplished fact[6] To freeze and store a few bottles of blood at this temperature is fairly simple, but to freeze a blood bank to this temperature would be a major engineering problem Washing of red blood cells after storage, to remove glycerol, is also no simple matter when large volumes of cells have to be treated Progress towards the solution of these practical problems was discussed by Dr P L Mollison An account of the successful transfusion of red blood-cells after three months' storage at −20°C was particularly encouraging If blood can be kept at this temperature large-scale storage of frozen blood may soon be feasible

DISHARMONY IN HYBRIDS?

THE family doctor is from time to time consulted about a proposed inter-racial marriage There may be serious risks to many such marriages from the different social backgrounds of the partners, but there are also often held to be risks that the children may show disharmony of physical growth Trevor[7] has assessed and analysed all the information he could find on physical measurements of racial hybrids In many ways this information is deficient the original parents, living perhaps 300 years ago, were of course not available for measurement and some related family group had to be measured instead, the techniques of measurement used are not always clearly stated, and the composition of the two parent races is not always as clearly known as in the Norfolk Islanders, who are more or less equally derived from English seamen from the *Bounty* and Tahitians But certain general conclusions emerge Thus for nearly every character the mean values for the hybrids lie between those for the two parental races, the distribution of measurements round the mean is approximately normal and shows no signs of bimodality, and the variation shown by the hybrid group is (surprisingly) not much, if any, greater than that of the parental races There is, then, no reason to expect disharmonious skeletal growth in the children of inter racial marriages

THE Nobel peace prize for 1952 has been awarded to Dr ALBERT SCHWEITZER, who for many years has worked as a medical missionary in Central Africa.

THE next session of the General Medical Council will open on Tuesday, Nov 24, at 2 P M, when Prof DAVID CAMPBELL, the president, will deliver an address. The Medical Disciplinary Committee will meet on Wednesday Nov 25, at 11 A.M

MAKING THE MOST OF PRESENT RESOURCES

SECOND HEALTH SERVICES CONFERENCE *

THE first conference of the Institute of Public Administration was held 2¼ years ago and at that time everyone agreed that what was needed in the National Health Service was more coöperation Mr HENRY LESSER, who took the chair at the second conference, held in London on Oct 28–30 remarked regretfully that no general pattern of coördination has emerged The popularity of the service with the public is beyond question, but the increasing cost, however is giving rise to anxiety There are two ways of using resources to the best advantage (1) by ensuring that the structure of the service is good and (2) by raising the standard of day to-day management

FINANCE IN THE DEPLOYMENT OF PRESENT RESOURCES

Mr LESLIE FARRER BROWN (secretary of the Nuffield Foundation) recalled that of the £500 million we spend on the N H S, 60% goes to the hospital service, 30% to the practitioner services, and 10% on the rest or breaking it down another way, 60% goes on wages and salaries and 40% on materials. The increases have been mainly in salaries and wages partly in increases of staff and salaries and wages must always be the chief cost Inevitably we have to ration our resources no country can meet all the potential medical needs of its people. If we think that £x million should be spent on the general practitioner service we must be ready to suggest what else can be cut down to allow for it. The quality of personnel is of the first importance for judgments are made by people and better judgments will be made by better minds supplied with better information and spurred to achieve better results We must study scientifically the ways of doing things, and pass on the knowledge gained to those working the service We must also make up our minds he said, whether we want decentralisation of authority or more centralisation for the present compromise is most unhappy

Prof R M TITMUSS (professor of social administration in the London School of Economics) said that resources are being wasted because of factors outside the health service If we take no steps to control road accidents we must expect more demands on casualty departments. If we insist on building 2 bedroom houses we must expect to give more custodial care to the aged sick Little thought is being given to these preventive factors We are concentrating more today on getting the general practitioner into the hospitals than into the local community service A small London investigation into the use made of the social services by people over 70 living alone revealed that only 1 in 40 of them had learnt of these services from their general practitioners: they had usually learnt of them from neighbours, friends or conversations heard in buses The highest demands on the services of practitioners and hospitals comes from a relatively small group of the public—from the aged the disabled, the victims of road accidents, mentally sick adults, and emotionally disturbed children If preventive work could reduce the demands for treatment from this group then the costs of the service might be reduced by as much as 20% We *must* integrate the family doctor with the local welfare services. From the medical staffs of hospitals we need a greater sense of personal responsibility and a greater loyalty to the whole purpose of the hospital rather than to their own specialty

Mr J C DAVIES (chairman of the Fountain group of hospitals) believed that every organisation could be more economically run and advised members of all committees not to concern themselves merely with things in the process of change—which are naturally brought to their attention—but also with the things which are continuing and therefore apt to go unscrutinised Cost-accounting allows comparisons to be made not only between one hospital and another, but also between costs in the same hospital at different periods. If a hospital could use the money it saved for other purposes within its own economy there would be more incentive to save and he suggested that the service needs an economy salesman, to point out the rewards of thrift.

Mrs. ORMEROD speaking from long experience gained on hospital management committees, agreed that there has been a decrease in social responsibility among medical members of hospital staffs, though when they and their wives had to raise money for the voluntary hospitals they responded splendidly They are also reckless in the use of woman power in the form of nurses almoners, and record clerks Mr C S BANGAY (clerk to the London Executive Council) thought the partition of the service under three heads makes agreement harder to arrive at than a truce in the Far East. He favoured the establishment of a central coördinating body and the removal of the Ministry of Health from the service

Mr GEORGE WATTS (secretary of the Oxford Regional Hospital Board) suggested that hospitals should allocate a small sum to research into methods of work on their own premises One such survey in a general hospital had already pointed the way to possible savings; and the Oxford R.H.B were consulting industrial experts about economies in the laundry and catering departments.

Other speakers emphasised the need for a common method of financing all parts of the service the economies to be hoped for from prevention of disease and better health teaching the importance of good food and the great cost to the country from road accidents and accidents in the home In replying Mr FARRER BROWN confessed to favouring removal of central control from the Ministry of Health and giving it to an all purposes health board, with subsidiary health boards at regional and local levels.

DOMICILIARY AND OUTPATIENT SERVICES

Dr A LESLIE BANKS (professor of human ecology at Cambridge) spoke of the changing pattern of disease in our time and the shift towards middle and old age in the hospital population Our investigation services, he said, have nearly reached saturation point, and the rapid turnover in the wards is a strain on the inpatient services Much investigation formerly done in the wards is now done in the outpatient department and more could be done there if quarters were not cramped and if the special departments added to the hospital when the pace was slower could cope more quickly with the work reaching them At present they are bottlenecks wasting time and money Lack of adequate appointments systems also wastes time—the patient's working time—and loses us money The time of general practitioners, too is wasted unless they can get speedy reports from special departments He thought that before extending the domiciliary services we should improve those we have, improve outpatient facilities and train a corps of administrators to deploy our resources better

Dr KENNETH COWAN (M O H for Essex) said that the right person to deploy our domiciliary resources is the general practitioner; and he needs to know what they are The local authorities should make their services readily available the Government provides help and money for the disabled and there are vast voluntary services not used to their full extent He thought it strange that little has been done to provide a domiciliary geriatric service comparable to the geriatric service now provided in hospitals for the chronic sick Plenty of trained nurses could be found to look after postoperative patients in their own homes Domiciliary midwives are often unemployed while hospital maternity beds are full There are thus many resources which administrative bodies are failing to use Regional surveys might be made of special problems, and of facilities for dealing with them

---

* The programme and papers of the conference have been printed by the Institute of Public Administration, Haldane House 76A, New Cavendish Street London, W 1

Dr A BEAUCHAMP (vice-chairman of the Birmingham Executive Council) thought postoperative pre-convalescent patients might certainly be nursed at home, provided the home is suitable The general practitioner knows, and can—if asked—report on, the home He suggested the reorganisation of outpatient departments If appointments systems were used, the space wasted on outpatient halls could be used for other purposes The patient who comes at 9, when the consultant is not going to turn up till 11, has not only a long wait but a *worrying* wait, and it is bad for him. Mothers should be encouraged to have their babies at home our midwives are first class, our home help service getting better and better To deliver a mother in hospital costs the country £40 for a fortnight's stay Again, we are not teaching people to live healthily when we herd them into overcrowded houses in a smoky atmosphere

Other speakers mentioned the failure of some hospitals to inform the general practitioner when a patient leaves hospital

Dr A TALBOT ROGERS, chairman of the General Medical Services Committee of the B.M.A , thought the general practitioner should use the outpatient department for purely consultative purposes, and the patient should come back to him when the consultant has reached his diagnosis Sometimes patients go on attending for months, perhaps so that a keen registrar can watch their progress It is right that a patient should be seen again after an operation, but it is not right that the outpatient department should take over what the family doctor ought to be doing

Dr G M WILLIAMSON said that in Leeds they have formed a general-practitioner-hospital relationship committee which has already done grand work Moreover, the geriatric committee of the regional board moves round the area and holds conferences, each lasting a day, with general practitioners, medical officers of health, and all others interested This practice has been much welcomed

A surgeon said that what he and his colleagues used to think of as "our hospital" was now one of a group, with its administrative centre six hours' journey away In defence of his brotherhood he added diffidently that he was punctual, wrote his letters, and kept a social dossier of every patient he saw Dr R I MACALLUM (Newcastle) also spoke well of the punctuality of surgeons, and reported on the good success of an appointments system so arranged that the consultant was able to see up to 20 new patients by a certain time

In reply, Professor BANKS noted that the discussion put the general practitioner right in the centre of the picture There is nothing radically wrong with the service, but we want, he said, three things we want to know how much we can spend, we want the best administration we can get at the local level, and then we want to leave the damned thing alone for five years

THE WHITLEY SYSTEM

Mr K J JOHNSON (a member of the ancillary staffs Whitley Council), in his printed contribution, explained that the Whitley Councils are made up of two sides, one representing employers, the other employed Decisions are reached by agreement of both sides, there being no voting *between* the sides, though there may be voting *within* the sides Failure to agree leaves both sides free to seek arbitration He said (at the third session of the conference) that he represented the employer's point of view The decisions of the councils are often shown to result in anomalies of pay and conditions, and the machinery is said to take an unconscionable time to work, but while he agreed that these allegations are true he thought the work of the councils must be judged as a whole and that it would be difficult to speed it up One cause of delay, he believed, is the too common appeal to arbitration Many of the appeals are trivial, even frivolous He criticised the composition of the [illegible] side Organisations which are already [illegible] on it are naturally not willing to cede places to any new organisations which may be formed, so these sometimes find it very difficult to get representation Again, both sides of the council ought to have [illegible] responsibility for the conduct of the service, but it happens that the employer side have to be responsible for the cost, while the employee side have to put the interest of their members first. The agreements of the councils are thus nearly always a compromise, and should be accepted as such

Dr JOHN GIBSON (formerly medical officer of [illegible] for Huddersfield) wished to see better coördination [illegible] results It should not be possible for a nursing orderly to receive, in some circumstances, more pay than a State-registered nurse working the same hours Nor is it reasonable that a non-resident nurse working [illegible] than 40 hours a week should get her meals and uniform free, whereas if she works more than 40 hours she has to pay £30 a year for them Nevertheless, negotiating machinery is necessary, and he hoped to see the weak spots in the Whitley council system strengthened.

Mr S G HILL (superintendent of the General Hospital, Northampton) agreed that there were anomalies but added that, in the health service, posts with the same name might vary very much in the demands they make on the officer holding them He thought there was a case for making some posts "non-Whitley" He agreed that new employee organisations tend to be unrepresented on the councils

Mr BANGAY (clerk to the London Executive Council) deplored the lack of knowledge of conditions on the management side The fact that the representatives on the employee side are all men may explain, he said why women in the third grade get less money than men in the first grade He suggested that some arrangement allowing for merit awards would be helpful. The idea was treated sympathetically by other speakers Several, too, agreed with him that the employer side is often not well informed about conditions of service

A speaker from the mental hospital service rated the councils with both humour and good humour for their dilatory behaviour, which, he said, is causing the wastage of 80% of mental nursing recruits and accounts for a deficit of 20,000 female and 8000 male nurses in the mental hospital service At present one girl often has to look after 55 acutely ill mental patients A male nurse, after qualifying, works for 9 years before he gets as much pay as a resident ward orderly, and a female nurse may work 8 years as a staff nurse before she gets a staff nurse's pay

Sir ARTHUR HOWARD, chairman of the Whitley Councils, defended them as well as he could the people who serve on them are not perfect and may not always make perfect decisions there will always be anomalies but the object is to satisfy members of the health service that they are getting justice, and in the main the councils are working well Subsequent speakers mentioned several striking anomalies, and Mr Johnson in replying, summed up the rather disgruntled [illegible] of the meeting when he said that if the Whitley Councils did not represent an ideal hole, he at least didn t know of a better one.

USING MAN POWER TO THE BEST ADVANTAGE

In the absence of Mr H A GODDARD, who lately directed the *Nursing Job Analysis Enquiry* for the Nuffield Provincial Hospitals Trust, the third session was opened by Mr P H CONSTABLE (house governor to St. George s Hospital) Over 60% of the cost of the N H S., he said, goes on man power some of which is wasted in coping with obsolete buildings We have too long based our policy in hospitals on opinion instead of facts. The nursing job analysis has given us facts some of which are disagreeable Many people find it hard to believe, for instance, that the end result of nursing is administration. He quoted a *Lancet* editorial which summed up the position "The student nurse is so little of a student and so much of a nurse for the same reason that the sister is so little of a nurse and so much of a clerk. Similar job analyses are needed, he said in every branch of the hospital service. He suggested that the hospitals might themselves finance such studies

Sir ZACHARY COPE (chairman of the Medical Recruitment Committee, 1953) advised using our facts with discrimination We should gain some useful information, he thought, if hospitals would compare their volume of work, and the numbers of their staff, in—say—1938 1946 and 1953 Such a comparison would show whether there had been too great an addition to cost, and could be made more cheaply than a job analysis He mentioned Mr Goddard s opinion that we have enough nurses to man all our hospital beds if they were properly distributed. But it would be hard to distribute them properly without direction, and rather than direct we must induce—by offering special advantages in those fields where they will not work at present. In outpatient departments, 75% of the work done by nurses could be done equally well by chaperons He thought the medical staff would be intolerant of job analyses. The N.H.S has inherited from the voluntary system the custom of appointing a consultant to several hospitals, often far apart, so that he travels long distances Man power would be saved if in future, doctors were appointed to hospitals nearer their homes. Appointments systems, though laudable have the drawback that they allow the consultant to limit the number of new patients he will see at a session and some doctors are so conscientious about examining their patients that they find they can only see 3 or 4 In the old days the consultant saw all comers. Mr Goddard, in the paper printed and circulated to the conference, said that the visiting teams of consultants sent out to hospitals by the Ministry could not expect in the time at their disposal to find out facts as effectively as a job analysis. He has taken part in the work of such teams and believes they can be quite effective.

Miss HELEN M. KEYNES (St. Ebba s Hospital Management Committee) had found doctors ill company on committees because, she said they seem to want to upset the committee and run the hospital themselves. Some other speakers seemed to have had similar experiences.

A member of the Scottish Dental Association said that neglect of children s teeth under the N H.S means increased expenditure later Mr A. ASHWORTH (Mansfield) deplored the General Nursing Council s policy of subordinating every other consideration to the student status of the nurse thus making it very difficult for some hospitals in the provinces to staff their beds Miss F F LILLYWHITE (G N C) pointed out that the Council is charged with the training of nurses and not with the staffing of hospitals; but Sir Zachary Cope rejoined that it is impossible in this instance to consider training apart from staffing

Mr W S WILKINSON (Secretary, Pharmaceutical Committee, London) mentioned the delays patients suffer because people will not take the responsibility for making quite trivial decisions—illustrating his thesis from the story of a prescription for a baby's truss which did not happen to be of the authorised size He also pointed out how much time busy people nowadays spend on committee meetings, and on travelling to and from them Here he said is another field for scientific study Mr COLIN ROBERTS (North Liverpool Hospital Management Committee) spoke of the saving possible on domestic work in hospital if the domestic staff are taught how to use the labour saving devices provided, and if their health and welfare are supervised.

Mr JOHN GRANT said that doctors employed in a hospital should not be appointed to the board of that hospital This remark brought more applause than any other at the session—to the disappointment of Sir Zachary who had never encountered any friction on his hospital board over forty years. Mr Grant and other speakers favoured further job analyses in hospitals Dr GLYN HUGHES saw the force of not encouraging consultants to work too many sessions at hospitals too far apart, and thought that when the journeys became a burden to him some of the older man s appointments should be transferred to younger men Nevertheless he thought it was important for general practitioners to keep the link with hospital consultants which such sessional visits provide He agreed that outpatient departments should be used for consultative purposes, not for long term treatment. He believed the visiting teams from the Ministry can do a good job

Mr CONSTABLE, in replying remarked that the G.N C do in fact, give very careful consideration to the difficulties of provincial hospitals over recruitment of nurses

THE DRUG BILL

In a paper on the Medical Profession's Contribution to Economy in Prescription and Treatment Dr A M G CAMPBELL (consultant physician to the United Bristol Hospitals) pointed out that the increased cost of prescribing could not be attributed solely to the fact that the State paid the bill for the actual cost of drugs and dressings had risen fantastically during the past few years. In hospital the largest single item on the drug bill was antibiotics At the Bristol Royal Hospital an economy committee, consisting of 5 members of the staff, including the pharmacist reviewed expenditure each month and they were trying to instruct residents and students in the economical use of drugs, especially antibiotics. They had installed diagrams and charts in the wards, showing the effective range of the drugs and pointing out their abuses and members of the staff had helped in the preparation of a small booklet [1] on the use of antibiotics On the question of proprietary and non proprietary preparations, Dr Campbell said that it was quite clear that in many preparations the *B.P* compound was just as good if not better than the proprietary one and very much cheaper In Bristol the hospital pharmacists had been asked to dispense wherever possible, *B.P* drugs instead of proprietary preparations, unless specifically ordered by the consultant Dr Campbell suggested that the College of General Practitioners could profitably examine the question of economy in the use of drugs and he hoped that the college would include in its plans for research trials designed to compare the results obtained with proprietary and non proprietary drugs

---

[1] See *Lancet*, 1953 i, 837

Dr Campbell was unable to attend the conference to present his paper, which was introduced by Dr H L GLYN HUGHES (senior administrative medical officer of the South-East Metropolitan Regional Hospital Board) Dr Glyn Hughes thought that a consultative outpatient clinic should remain consultative and that the patient should not be referred to the hospital dispensary for his drugs

In the matter of proprietary drugs, Mr J C HANBURY (vice chairman of Allen & Hanburys Ltd), who opened the discussion, favoured a compromise between an absolute ban and a continuation of the present state of affairs If non-proprietaries alone were permitted, many firms with low overhead charges, but not necessarily the best facilities for preparing drugs, would enter the market with cheap non-proprietary compounds These might satisfy the letter of the law, but they could not be produced with that careful regard for detail that often had considerable effect on the ultimate therapeutic efficiency of a drug

Dr STANLEY THOMAS (a member of the Medical Practices Committee) disagreed with Dr Campbell's view that the G P was influenced by postal advertisements to a greater extent than his hospital colleagues Dr Thomas had had letters from consultants which showed that he and they were receiving inspiration from the same piece of blotting-paper

Dr W D HOOD (senior medical officer, Department of Health for Scotland) thought that hospital pharmacists had a considerable part to play in the planning of more economical prescribing, and he suggested that their views should be sought more often

Dr TALBOT ROGERS said that though G.P s were now being told something about the cost of prescribing they still did not know whether they were keeping in step with their colleagues in the same area The General Medical Services Committee had asked for the restoration of areal averages, which would enable doctors to see how their own prescribing costs compared with the average for the area But the work of pricing N H S prescriptions had been considerably in arrears and it had not been feasible to undertake this additional task The situation was now improving and it should be possible to start preparing areal averages next year The intelligent use of these averages and the list of comparative costs that had lately been sent to G P s would be a considerable help in reducing the drug bill

REGIONAL PLANNING

In his discussion of Medical Planning in the Regions, Sir FRED MESSER, M.P (chairman of the Central Health Services Council), made some controversial proposals which drew surprisingly little return fire The Ministry of Health, he declared, should not run the National Health Service there should be a National Health and Welfare Board, something along the lines of the Central Health Services Council This board should have the over-all responsibility for the administration of the service Hospital regions should be reduced in size, and regional boards should have authority over hospital administration Combined action by regional boards and local health authorities was often hampered by the present geographical arrangements, and it would be a great help if the regions were reconstructed to conform to the boundaries of a group of local authorities Sir Fred also proposed the inclusion of teaching hospitals in the regional service , and he was anxious that the ambulance service should come under the control of the regional boards and not the local health authorities as at present Since the start of the service, medical planning had progressed, but not in all sections of the service The emphasis had been on the hospital service and not enough attention had been given to the preventive side

Dr T LLOYD HUGHES (senior administrative medical officer of the Liverpool Regional Hospital Board) believed that regional planning had largely justified the claims that had been made for it, though certain circumstances still prevented the system achieving the benefits of which it was potentially capable Among these circumstances he included the lack of unity, which was the result of the service's division into three parts, and the shortage of nurses and doctors, particularly of doctors for junior hospital jobs

Dr T A MORRISON (chairman of the Bright executive council) put the point of view of the G P He thought that regional boards might be thinking in terms of hospital units that were too large , there was perhaps a place for smaller hospitals where the G P could treat his patients himself under the supervision of a consultant He was critical of the school and antenatal clinics of the local health authorities , nothing was done there that the G P himself could not do

Sir Fred Messer had referred to the difficulties that had arisen in coördinating the various parts of the [illegible] while its present structure was retained, and Sir ALLEN DALEY (formerly M O H for the county of London) took up this point In his view these difficulties were due more to lack of time than lack of inclination on the part of those who were helping to run the health service There was certainly not an unlimited number of people able to give time to committee work, and more and more tasks became heaped on the willing horse He agreed with Sir Fred that the present hospital regions were too few and too big , a teaching hospital should be associated with every region, but it need not necessarily be within the boundaries of the region

---

International Congresses

PÆDIATRICS

THE Seventh International Pædiatric Congress held in Havana from Oct 12 to 17 It was preceded by the 22nd annual meeting of the American Academy Pediatrics in Miami from Oct 5 to 9, to which the European pædiatricians attending the in congress were invited

The congress followed the usual system of pl sessions and round table conferences , and there was an excellent scientific exhibition, in which the displays on nephrosis, epilepsy, mucoviscidosis, and tuberculosis were especially notable The plenary sessions were devoted to epilepsy, congenital heart disease susceptible of surgical treatment, prematurity, the complications of primary tuberculosis, and problems of metabolism and nutrition

The paper by Prof STANLEY GIBSON (Chicago) on Eyes, Ears, and Hands in the Diagnosis of Congenital Heart disease was a masterpiece of clinical observation and Dr HELEN TAUSSIG's review of the operations performed at Baltimore was on an equal plane

Prof CLEMENT SMITH (Boston) discussed the "hard core" of the mortality among premature infants, Prof ALAN MONCRIEFF gave a graphic account of the changes in the care of premature infants during the past twenty years

In the session on tuberculosis it was encouraging find that more and more authorities are abandoning intrathecal treatment in tuberculous and other forms of meningitis, and that isoniazid has worked greater miracles in childhood tuberculosis than it has in adults Dr EDITH LINCOLN (New York) discussed the effects of chemotherapy on the prognosis of primary infection and Dr BERNARD SCHLESINGER described the local complications of the primary complex

Of the twenty round tables the most popular appeared to be those on nephrosis, hæmatology, allergy, and liseases. Professor Moncrieff was a member of the panel n respiratory diseases of the newborn, and Prof Wilfrid Gaisford (Manchester) of that on B C G

The congress was well attended nearly two thousand nembers from 47 countries, were present.

The next congress, in 1956, will be in Copenhagen

NEOHIPPOCRATIC MEDICINE

FOUR hundred physicians from all over the world took part in the Second International Congress of Neohippocratic Medicine held at Evian in the first days of September

The congress began with the reading of the opening address of the president, Prof M H LAIGNEL-LAVASTINE Paris) who unfortunately was prevented by illness from being present. In his address Prof Laignel Lavastine pointed out that the term neohippocratism' coined by A. P Cawadias in 1919 did not signify a return to Hippocrates but an attempt to combine the scientific analytical approach predominating in contemporary medicine with the synthetic holistic, and constitutional approach of Hippocratic medicine

The following conclusions were reached by the congress

1 Internal medicine and thus the internist must take a preponderant place in medical practice Specialties are necessary on account of developments in technique, but as disease is a total ' psychosomatic " reaction, synthesis between the parts and the whole is necessary for a precise diagnosis.

2. Clinical observation must be reinstated as the most important factor in medical diagnosis because only clinical observation and the clinical critical spirit allows the understanding of the patient as a whole and thus laboratory signs are to be interpreted in the light of clinical observation

3 Consideration of the constitution of the psychophysical personality of the patient, and his physical social and historical environment independently of his disease is of the greatest importance in diagnosis and treatment

4 Parallel with the specific methods of treatment indicated by the particular disease and developed in modern medicine the constitutional Hippocratic methods adapted to the constitution of the patient, independently of his disease should be applied.

A great part of the success of this meeting was due to the untiring energy of the secretary general Prof Pierre Delore of Lyons.

Parliament

Operations on Animals

IN the House of Lords on Oct. 27 Lord STAMP moved the second reading of the Protection of Animals (Amendment) Bill. He said he realised that obviously the measure could not go any further in the expiring session but he hoped that the Government would take it up and give it their support in the new session or failing that a private member would reintroduce it. The main object of the Bill is to bring up to date the law concerning the use of anæsthesia in operations on animals [1] Lord CARRINGTON joint parliamentary secretary to the Ministry of Agriculture said that while the Government supported the Bill in principle, they could give no undertaking that they could find parliamentary time to take it up

QUESTION TIME

National Service Medical Boards

In answer to a question Sir WALTER MONCKTON Minister of Labour said that he had visited a number of National Service medical boards, and had had discussions with chairmen of other boards and officials and had attended meetings of chairmen in all regions. These investigations had satisfied him that the medical men who comprised the boards were fully alive to their responsibilities Nevertheless some errors in grading had occurred. Special investigation of cases brought to his notice, including those raised by hon. members since the end of June last, had revealed about 20 such cases which was not a large number in relation to an annual rate of about 300 000 examinations. The most common factor resulting in a man being placed in too high a grade was the failure on the part of the man to disclose his full medical history; unless a man disclosed his full medical history the board conducted his examination at a disadvantage To correct this source of error the notice summoning the man had been revised and now advised him to bring to the board medical evidence of any past disabilities and ailments.

In a few cases there had been a lapse on the part of the board in applying the proper medical standards, and in other cases there had been clerical errors. The remedy for such mistakes was patient and constant attention to detail by the medical boards when applying the standards laid down. To help towards this the chairman would be relieved of any non medical work which might be a distraction. To provide a further safeguard against errors, in future every man summoned to a medical board would be informed by notice that if he had reason to think that he had been given a wrong grading he might appeal in writing within fourteen days enclosing with his appeal any medical evidence he might desire to submit Such appeals would be referred to the regional medical officer of the Ministry of Health for advice whether medical grounds existed to justify re-examination. Ordinarily any re-examination would be undertaken by a different board Sir Walter added that nothing he had said should be regarded as a reflection on the manner in which the general body of chairmen and members of medical boards had performed their duties Their task was not easy and he could assure the House that they had maintained the high tradition of their profession.

In answer to further questions Sir Walter said he was keeping this matter constantly under review He had not stopped examining cases and causes and would not hesitate to take what action he thought right. But in spite of the publicity the number of avoidable errors was very small

Food-poisoning

Replying to Dr BARNETT STROSS, Mr IAIN MACLEOD the Minister of Health said that 300 outbreaks of food poisoning in England and Wales had been notified to him between Jan 1 and Oct. 21 1953 by medical officers of health The number of people affected according to the causal organism, type of food, and the place was as follows:

	Outbreaks	Persons affected
Causal organism		
Salmonella group	117	2309
Staphylococci group	01	2118
Cl. welchii	11	461
Miscellaneous	14	134
Unknown	97	951
	300	5966
Type of food:		
Meat and meat products	109	*605
Fish and fish products	1*	75
Duck eggs	12	15
Milk and milk products	20	1775
Miscellaneous	15	58
Vehicle of infection not established	133	1438
	300	5966
Place of outbreak:		
Hotels, catering establishments, &c.	24	29*
Schools	25	1970
Factory canteens	17	467
Camps	2	181
Hospitals	10	405
Local authority institutions	3	319
At home	132	1418
Other places	12	470
Unknown	60	444
	300	5966

The White Loaf

In reply to Dr STROSS Dr CHARLES HILL, parliamentary secretary to the Ministry of Food said that precise information as to the response of the public to the availability of the white loaf would not be available until the December claims for bread subsidy came in from the bakers. It appeared so far that while there were many local variations the total transfer of demand from National to whiter bread was small He had no doubt that the National loaf was the healthier loaf what had been done was to give the public freedom of choice

---

[1] See *Lancet*, Aug 15 1953 p 347

Flour Improvers

Dr Stross asked the Minister of Food when the use of agene as a flour improver and bleacher would be discontinued, and what other substance would be used in its place — Dr Hill replied Although good progress has been made the investigations are not yet complete I hope, however, to be in a position to make a statement within the next three or four months

Milk-borne Diseases

Replying to Dr A D D Broughton, Dr Hill said that 48% of the population of England and Wales, and 63% of the population of Scotland, resided in areas specified by Orders which had been made, or which were now laid in draft, before Parliament for the purpose of protecting the public against milk borne diseases

Royal Commission's Terms of Reference

Replying to a question, Mr Macleod said that it would not be appropriate to extend the terms of reference of the Royal Commission on the laws relating to mental disorders to cover the law with regard to homosexual cases and their medical treatment In so far, however, as they might be suffering from mental illness or mental defect, their position as regards certification, detention, and care would be covered in the same way as that of other persons so suffering

Medical Services on Royal Yacht *Britannia*

Replying to a question, Mr J P L Thomas, First Lord of the Admiralty, said that 200 hospital beds could be accommodated in the royal yacht, the estimated cost of supplying and equipping these beds and ancillary medical services was approximately £12,000

Nurses' Pay in R.A F Tuberculosis Wards

Replying to a question, Mr George Ward, under-secretary of State for Air, said that an extra 3*s* a day was paid to nursing officers of Princess Mary's Royal Air Force Nursing Service below the rank of wing officer when employed full-time on nursing pulmonary tuberculosis cases Airmen on this work were given an extra 6*d* a day, and airwomen an extra 5*d*

Mr P F Remnant Does the Minister deny that there are any special risks in serving in these wards on account of the precautions taken ? Mr Ward There is no evidence that the incidence of tuberculosis among, for example, R A F ward orderlies is higher than the incidence in the R A F as a whole, and any extra risk is counteracted by the precautions taken.

Dr Edith Summerskill Is the Minister aware that the younger these individuals are the greater is their vulnerability to this disease ? Does he consider 5*d* sufficient compensation for the risk these girls take ? Mr Ward One test to which they are subjected before being allowed to undertake this work is the Mantoux test, which shows whether or not a person is liable to tuberculosis Mr A Woodburn Is the Minister aware that the health authorities do not regard it as desirable that it should be suggested that the nurses in this type of nursing are open to any greater risk than they are in an ordinary accident ward, where a proportion of the patients may be suffering from tuberculosis, just as in tuberculosis hospitals ? Mr Ward Yes, Sir As far as the R A F is concerned, our practice is in conformity with the practice in civil hospitals

Myxomatosis

In answer to a question, Sir Thomas Dugdale, Minister of Agriculture, said that all reasonable practicable steps were being taken to stamp out the only two known outbreaks of myxomatosis that had recently come to light in Kent Measures were also being examined for the protective inoculation of tame rabbits in case myxomatosis should spread Future policy would be determined in the light of recommendations from the advisory committee which he and the Secretary of State for Scotland had set up and which is holding its first meeting next week.

The chairman of the committee is Lord Carrington, and the members include Dr C H Andrewes, F.R S

In England Now

A Running Commentary by Peripatetic Correspondents

In Cuba now—or at any rate a short while ago—the pædiatricians assembled for their international congress had castanets for breakfast and music most of the time. Since parliamentary government is temporarily suspended, the beautiful National Capitol in Havana was available for the main events of inauguration and registration Conveniently across the road (crossed by keep-to-the-left motorists at great peril) was a air-conditioned cinema which housed the main [illegible] by day and Charlie Chaplin in what was obviously the Spanish equivalent of *Limelight* by night Projection was not always as good as might have been expected in a cinema, but the simultaneous walkie talkie translation apparatus was mostly a boon

Quite suddenly, so it seemed, it was decided one [illegible] to take all the congress (said by now to number up [illegible] 2000 with wives et al) thirty miles to see a n[illegible] orphanage-technical school for the children of [illegible] Coaches were to leave at 11 A M.—well, 12 noon—but then there was a mass photograph, so we embarked [illegible] 12 30 and about 12 50 we were installed all along [illegible] charming sea front where the north wind of early N[illegible] was blowing spray on to the road Finally all [illegible] assembled and off we went In front two motor-cycles carried the Cuban equivalent of "traffic cops" with screeching syrens followed by the President of the Congress Pot-holes added hazards to the early part of the journey, the principle being that it was stupid to repair them until the rains had really ended (? November). Yet marvellous new buildings had to be inspected on arrival while blood-sugars sank lower, and it was nearly 3 P.M. before we sat down to be waited upon in a vast dining-room by girl orphans who looked like a chorus from *Daddy-Long-Legs* or *Love from Judy* Round-table study groups had been scheduled for 2 P.M and many had been lured on the drive by the statement that they were to be held at the site of lunch, but this was cancelled so all except those who attended the "Grand Council" were whisked back to town again, screaming past red lights—the syrens, not the delegates—for a late start Unfortunately the "round table" included several members of the council and this group did not get going till next day, 27 hours and 20 minutes behind official schedule

The local rum cocktail gave great pharmacological interest to the proceedings One bar appeared to give these away at lunch-time, and many pædiatricians found they just could not compete with the bar-tender There was a touching sight of a tough Texan (probably) staring sorrowfully at a row of drinks on which he was fighting a losing battle At my hotel two drinks for the price of one encouraged the unwary to start at 5 P.M. One theory was that rum deadened the noise outside, which seemed unending, although a British pædiatrician awake at the uncomfortable hour of 4 A.M. asserted that it was quiet then The famous Morro Castle (about the same age as the Royal College of Physicians of London) contained a working life-size model of the garrotting machine, and at least one member of the inspecting party left hurriedly as a voluble guide demonstrated its use

* * *

I rush from my operating-list to the outpatients and then on to a ward round But one of the joys of "the end in sight" is to relax with the last few patients and hear something of their views on life and their ways of living My latest patient friend is a farmer and a cheese-maker who relaxed once too often in the presence of his bull "This penicillin," he says, "may be a wonderful thing for me in here, but it costs me thousands outside. Now and then, and it is becoming an increasingly frequent occurrence, we find that thousands of gallons of milk won't make cheese The 'starters' are not there, and it is all thanks to penicillin which is being used in the treatment of mastitis in cows" "What's the answer?" I ask him He shrugs his shoulder philosophically "At present none, but of course it isn't all waste. The milk is still fit for human consumption"

My tired mind goes back to the little boy I saw early in the day He had osteomyelitis presenting with [illegible] sions, one in his femur on the right side and the other his tibia on the left, and the organism has proved trangely confident in the presence of penicillin despite he assurance of his family doctor that as far as he knows he boy has never had penicillin I remember two other atients I have seen lately with multiple lesions and the ittle girl with the pyogenic abscess so chronic that it ppeared almost a tumour Perhaps the milk that has o "starters but is fit for human consumption fits into he jigsaw somewhere No matter with what benevolent ntentions we interfere with the balance of Nature we o it at a peril

* * *

Our tame psychiatrist refused the offer of a couple of oose eggs, but his small boy was persuaded by the ardener to put them under his bantams The cock and is three hens got straight down to the job, never less than wo of them sitting at any given time on the eggs till hey were hatched The cock, who took his fair share of he work of brooding, now proudly leads his wives and he two goslings round the garden. Surely an ornitho-ogical event of the first importance, and perhaps unique?

* * *

The placebo has been receiving a lot of attention lately, ut no-one has mentioned what I call ' placebo diag osis '—the common everyday terms we use in a busy urgery Two popular ones are

Teething—I may explain to a mother that her fretful child ho is not really ill is teething The mother who really knew his all along, goes away happily and no doubt gets on with he child better now she is sure what ails it I know that no-one nows what *symptoms (if any) teething causes* *Some paedia-*ricians say it can cause none while others say it does cause yrexial illnesses that fall by crisis as a tooth appears. I had o trouble with my wisdom teeth, but I know doctors who o, and they firmly believe in painful teething I just don t now who is right but I go on using teething as a diagnosis. t satisfies the mother and when used wisely is harmless. No oubt it is sometimes correct

The Change.—This is one I do not like for what psychological eason I do not know Again no-one knows what if any ymptoms are caused by gonadal old age If the symptoms o, not indicate disease we may perhaps accept the patient s iagnosis (though I never proffer this one myself) Œstrogens o help sometimes, though whether a placebo would I do not now

Every doctor has his favourite diagnosis that in truth s not reasonable—catarrh, the monthlies, rheumatism, onstipation low blood pressure high blood pressure, erves, obesity, and dropped viscera. Psychoneurosis nd teething I use others still favour constipation or grumbling appendix. Yet others go straight for landular *fever or brucellosis. But why, oh why does the* atient seem quite content with the thought that he has gastric stomach or a cardiac heart?

* * *

We were gently tossing in Charlie s 16-ft. motor-boat, hiffling up and down the bay for mackerel and pollack. t was a grey day at sunset, just the day to catch fish Ve were using the new fangled snare of 16 feathered ooks, with which we had done so well only the other vening We were off the approved mark—Tonkin s ellar Row—where last year we caught 3 four pound ollack at one pull, and Roy had that fine sea bass. espite all these propitious occurrences we had no bite or the evening Charlie s normally cheerful face was lum I reckon tis more comfortable at home Ted —unheard of sentiments from Charlie at sea. Then we aw an old whiskered face lift from the seas about a undred yards from us. It was the seal that sometimes ooks on Holzephron or Parc Vean beach, out fishing for is supper

Ah, says Charlie, That ole seal s driven the fish way We ll go down along a bit. Sure enough, hen we got down off Gwinian Point there were pollack hick and fast, and we had good sport. Now what want to know is, if the seal has this effect on the fish n his neighbourhood how does he make his living fishing?

"Yes r he did a digitalis examination"
"Ah! with a foxglove I presume"

Letters to the Editor

VAGARIES OF INTELLIGENCE

SIR,—The pronouncements on the constancy of the I Q in your issue of Oct 24 have been widely quoted in the press, and I should therefore be grateful if I might remove one or two misconceptions

The criticisms of the I Q brought forward by the three young investigators whom you mainly quote are by no means as new as they suppose Dr and Mrs. Clarke declare that the fact of I Q variability can no longer be disputed. ' But who has ever disputed it? In criticising previous views they refer, among other publications, to an L C C report of my own and add these investigators rarely if ever submit their hypotheses to experimental proof. ' The report was first published, not in 1947, but in 1921 Results were then given for cases retested annually for 5 years, and I emphasised that the constancy of I.Q ' is but imperfectly realised. ' In later reports data were given for cases followed up for 25 or 30 years The experimental proof " of Dr and Mrs. Clarke covers an average period of 2 years 3 months only

In an earlier report (1917) I insisted that ' for scientific work the employment of the standard deviation (or its equivalent—the percentile) seems indisputably the best device," and merely proposed a quotient or ratio because it could be rapidly calculated and seemed more intelligible to magistrates and medical officers. The quotient,' it was explained, assumes as a first approximation that the changes in mean mental age and in the standard deviation are rectilinear, whereas in fact they are curvilinear " This simplification is the main (but not the only) cause of the inconstancy Your contributors seem to be wholly unaware that psychologists, not only demonstrated the existence and amount of error to be expected but showed how it could largely be corrected by adopting a more complex formula This entails a *statistical analysis of a rather elaborate type* the most recent suggestions will be found in an article by Dr Fraser Roberts,[1] based on tests applied at Stoke Park Colony and the Royal Eastern Counties Institution Every psychologist will therefore welcome what you say in your leader on the need for publicising the value of statistical research.'

One important cause of variation is not mentioned by your contributors—the fact that so many of those who employ (and criticise) intelligence tests have never been trained in their administration and interpretation. Dr Tizard states that an I Q of less than 70 is very widely accepted as evidence of mental subnormality sometimes on the basis of a single test Presumably he is referring to the standard proposed for certifying special-school cases in the days when such cases had to be certified Possibly some medical officers have relied on a single test But no trained psychologist relies on tests alone—much less on a single test—in any doubtful case

In your leading article you seem to confuse three different concepts that psychologists have carefully distinguished first, the innate general cognitive factor (γ), secondly the estimates obtained for such factor measurements (*g*); thirdly the vague qualities called intelligence ' in everyday speech To prove that the last can be altered by education or that the second provides only rough and fallible assessments is not to demonstrate that the first—an entirely abstract and hypothetical component—is subject to variability The psychologist, like the physicist, has adopted a popular word to avoid pedantic symbols and circumlocutions but, in criticising what he says about intelligence ' as he has defined it, arguments based on some other interpretation seem (if I may say so) merely to confuse the issue

MILLI-EQUIVALENTS

SIR,—In articles, often by clinicians, I note the liberty with which certain blood components are expressed in milli equivalents, yet other acid and basic radicals are referred to in a different value—e g , grammes per 100 ml or even as a " normality " Thereby the usefulness of the m eq expression as a convenient index in acid/base balance studies is lost , presumably the author only intends to convey the blood concentration of an element The actual estimates of such substances (K, Na, Cl, &c) by a laboratory are in terms of mg per 100 ml , and—which is more important—replacement is by a grammes per litre solution

In a recent authoritative paper a prescription for replacement therapy in cases of ileus is expressed in terms of both presentages and milli-equivalents Surely, Sir, this makes for confusion and opens the door to serious dispensing errors

True, by using a simple formula one method of expression is easily convertible to another, but for practical purposes it is surely more useful to retain mg per 100 ml —the form in which, I believe, most clinicians think, and of which they know the normal blood-levels

HYALINE MEMBRANE IN THE NEONATAL LUNG

SIR,—We must be grateful to your contributors who have recently established " hyaline membrane " in the lungs of the newborn as an important disease entity at long last It is evident, however, that some issues, which probably could be solved, are still confused

Dr Emery (Oct 24) must be correct in deprecating the application of either positive or negative findings in animal experiments to the human problem The animal fœtus differs from the human in various ways, notably the lack of a comparable coating of vernix caseosa, and the absence of anæsthesia in the mother The only satisfactory starting point for experiments cannot be obtained—i e , the human fœtus before it takes its first breath I believe there are enough experiments unwittingly performed at cæsarean section to enable us to forget experimental animals—especially those in which the animals have been breathing air for quite a long time

I do not share Dr Emery's view that the hyaline membrane of the newborn is comparable with membranes developing later in life—e g , in nephritis, rheumatic fever, and cardiac failure The nearest approach I have seen was in a patient with extensive amyloid disease It is this general (and I think erroneous) belief which has led to the disuse of the name " vernix membrane " While I do not suggest that " vernix membrane " is more than a part truth, it is a romantic name and the one I prefer To me at least, " hyaline membrane " not only contains no truth at all but leads us along wrong lines in research The Oxford dictionary states that " hyaline " means glassy The membrane in question is seen in routine sections (hæmatoxylin and eosin) to be an opaque dirty red—not my idea of glassy Because the name given to this membrane appears capable of arousing deep feelings I have suggested that we call it " alveolar-duct membrane," after its distribution There appears to be general agreement on two points only—that it occurs in alveolar ducts and that it does not occur in stillborn infants

There are three possible lines of inquiry, of which only the first lies predominantly with the pathologist

(1) What substances unquestionably enter the bronchial tree in stillbirths? Here it is necessary to point out that, with few exceptions, " sudden death " does not occur at any stage of our intra or extra-uterine life The commonest " sudden death " is coronary thrombosis, but this is not really sudden in the sense that everything stops just as it was I have, for example, never heard of an accident resulting from the " sudden death " of a car driver Likewise, the fœtus dying in utero does not just stop suddenly at a particular point in its development Whatever the cause, an asphyxial state develops This leads to the inhalation, firstly, of the substances already in the mouth and pharynx, such as mucus and nucleated epithelial squames, and, secondly, of liquor amnii with its suspended vernix caseosa, epithelial squames, meconium, &c

The amount of vernix entering the lungs is very variable, as might be expected from the variation in the amount seen on newborn babies It may enter the lungs in two ways: firstly, as amorphous masses of vernix itself (I recently examined the lungs of a stillborn infant in which there were great masses of it in the alveolar ducts and alveoli, but this is exceptional) , secondly, anyone who will examine a fat stain of skin from the groin and elsewhere will see that the epithelial squames are heavily coated with vernix, and that these squames are cornified and do not have a nucleus. I find it difficult to assess histologically the proportion of nucleated to cornified squames in the bronchial tree and alveoli, but my impression is that the former (of oropharyngeal origin) predominate Some obstetricians insist that these oropharyngeal substances are very important in the production of alveolar duct membrane Mr L O Watt evolved a technique for removing them from the upper air passages of the newborn (especially after cæsarean section) and he believes this produced a much higher proportion of healthy babies

Pathologists and pædiatricians must carefully findings of the obstetricians, for I feel sure that it will be the clues supplied by the obstetricians which will finally solve the problem

Originally, we thought the " vernix membrane " was entirely due to inhaled substances, now it is quite " low-brow " to think these have anything to do with it at all Surely the pendulum has swung too far To me alveolar-duct membrane has a complex and variable composition, it includes mucins, fats, epithelial squames and possibly unknown elements from the alveolar ducts and blood-stream Blood elements do not appear to be essential because there may be a thick membrane with no œdema at all, and there may be gross œdema with or without membrane

Dr C G Paine is probably correct in stating that the fat content of the membrane decreases with the age of the baby This may not be a fundamental observation because macrophages appear to attack fat before anything else. Vast numbers of squames may be inhaled without any membrane forming, and many membranes do not appear to contain squames It is difficult to believe that the squames are an essential element of the membrane, partly because they enter alveoli so readily, unlike the alveolar duct membrane

It is interesting to see that Dr Claireaux (Oct. 10) finds many nucleated squames in the deposit from the liquor amnii It is possible that these are contaminants from the maternal cervix and vagina, and that the fœtus could also inhale them before the membranes rupture or until the head is in the vagina It is difficult to tell vaginal squames from those formed in the oropharynx of the fœtus, they will not come from the fœtal skin Whatever their origin, there is no doubt that nucleated squames do gain access to the fœtal air-passages and often, I think, outnumber cornified squames with no nucleus

(2) I think it probable that the best line of inquiry is open to the obstetricians alone In my early work on alveolar-duct membrane, I was surprised to find that it was a common cause of death in babies delivered by cæsarean section. The must eliminate vaginal nucleated squames as the cause of alveolar duct membrane Some years before he retired from the staff of the Derbyshire Hospital for Women, Mr C G Lochrane was much concerned by the number of babies who died of this condition after cæsarean section. He discussed this with Mr R J M Jamieson (now his successor and they concluded that the probable cause was the failure to deliver the baby before it had become appreciably anæsthetised or cyanosed Mr Jamieson was given the task of administering this type of anæsthetic and the deaths ceased

Possible confirmation of this belief comes from Dr Pa who tells me that, of many cæsarean sections performed under local anæsthesia at the Jessop Hospital for Women, Sheffield, none has produced a baby who has died from alveolar duct membrane If this is so, then surely it is a vital observation in explaining the cause of the membrane.

(3) The third profitable inquiry is indicated in the article by Mr Donald and Dr Steiner (Oct 24)—an outstanding

valuable study I think that in time they will prove that alveolar-duct membrane is not always fatal In the past, radiologists have made a definite diagnosis of bronchopneumonia on the findings they describe In some of these I have found a normal blood picture and observed a normal temperature chart I have therefore concluded that they were cases of alveolar duct membrane which recovered though final proof was of course lacking

I doubt if Dr Steiner is wise to complicate the subject by including post-mortem pictures. Many of these will show oedema and not collapse The word 'collapse must be used with care because most of these lungs are not greatly reduced in volume The reason for this is that the respiratory forces lead to much ballooning of the alveolar ducts when the alveoli can no longer expand and contract normally—an appearance often erroneously called emphysema

I hope the work at Hammersmith will be continued indefinitely so that it will be possible to obtain a very long follow up in those cases of probable membrane which recover It is at least possible that the ballooning of the alveolar ducts which occurs when a membrane is present will be followed by bronchiectasis in later life

It is my belief that alveolar-duct (or hyaline) membrane is a lesion which is secondary to preventable causes It is more than probable that if the obstetricians pooled their knowledge and experience we would soon know instead of guess these causes

RESETTLEMENT OF DISABLED PERSONS

SIR,—Nobody in the medical profession has done more for the cause of rehabilitation and resettlement of the disabled than Sir Reginald Watson-Jones—as I know from personal experience

When a representative of the Ministry of Labour states that we in this country are away ahead in the solution of this difficult problem I think he has been allowed more than his quota of poetic licence Ahead in social legislation perhaps but in the general application of the principles of rehabilitation we can learn from other countries.

I have recently been the deputy director of the United Nations course on Rehabilitation of the Adult Disabled held in Sweden Finland, and Denmark Some Scandinavian countries can teach us the integration and coöperation of government services, the medical profession, and the voluntary agencies. It is this very integration that is missing in this country The unemployed disabled person is influenced by the Ministry of Health organisation whilst under medical control by the Ministry of Labour when he seeks employment and re-training; by the Ministry of Pensions and National Insurance when he requires an invalid carriage or when his sickness benefit is not forthcoming by the National Assistance Board when he requires extra help by the Ministry of Education if he is an adolescent and needs further education The various representatives of these official bodies give him conflicting advice In addition, he is also influenced by trade union representatives, lawyers, and well meaning friends and relatives He is also guided by the various voluntary agencies whose aims are to help the disabled Can it be wondered at that during the period of his rehabilitation he is confused anxious, and in the end frustrated

Rehabilitation, in my opinion is a medical problem, because without good health we cannot have good industry Resettlement is partly medical and partly the province of the Ministry of Labour Re-training must be controlled by the Ministry of Labour

Is it possible for us to remove the patient from the realms of "power politics ' and institute one authority empowered to guide the patient into the safe harbour of gainful employment? I believe if we spent less time in apportioning blame and gave more thought to what is happening to the patient s morale we should be rewarded by seeing disabled patients living and working happily—restored to life in its widest sense That is our aim

Garston Manor Rehabilitation Centre,

CHILDREN IN HOSPITAL

SIR,—As one who has over the last thirty years been associated with work in children s hospitals, particularly orthopædic hospitals, I should like to endorse the views expressed by Dr Mac Keith (Oct. 24) concerning children who require operative treatment.

Any attempt to bluff or deceive children is doomed to failure as they seem to possess a sixth sense by which they easily detect such efforts Nevertheless, operations and particularly orthopædic operations can be very painful unless the proper preoperative and postoperative treatment is given and I write to make a plea for the proper postoperative use of morphine for children

It seems that in some quarters there has arisen a tendency to teach that morphine is dangerous for children but I should like to record that after using it for thirty years according to the formula of age over age + 12 I have never had any anxiety Not only is it not dangerous but children in pain seem to thrive on it After an operation, such as arthrodesis of the hip the child who has had proper doses of morphine is found next day to have a good colour and to be comfortable but when meagre doses of 'Nepenthe have been given the child is pale and miserable

With the proper use of morphine it is possible to assure a child unreservedly that he will not suffer much pain; and the child awaiting operation will have observed that his next-door neighbour who has already had his operation had quite a comfortable time of it Under these conditions children fear operation much less.

Black Notley Hospital
Braintree Essex.
M. C WILKINSON

SIR—All who work with children will be grateful to Dr Mac Keith for his article One small criticism I would like to make is against the suggestion that, in preparing the child for entry to hospital for an operation he should be given a mental picture of the operating theatre and white-gowned nurses. Surely this is unnecessary since no child should be allowed entry into the operating theatre while still conscious?

South Devon and East Cornwall Hospital
Plymouth.
HUGH JOLLY

INTRA ARTERIAL TRANSFUSION

SIR,—Dr Brown's article (Oct. 10) on intra-arterial blood transfusion after controlled bleeding emphasises the advantage of the arterial over the venous route for transfusion in cases with prolonged hypotension and peripheral vasoconstriction after hæmorrhage.

While the radial artery is suitable for transfusion in cases such as his where the cannula can be tied in before vasoconstriction develops, the position is otherwise when the limbs are cold and exhibit severe vasoconstriction In such cases difficulty in inserting a cannula in the radial artery and in securing an adequate inflow of blood has been reported[1] Probably the chances of gangrene in the hand are enhanced in these circumstances, and the risk of this and other complications is by no means negligible. Thrombosis of the femoral artery has followed its use for transfusion,[2] so this route is not to be recommended

Dr Brown suggests use of the aorta as a last resort, but my experience indicates that no complications or difficulties attend intra aortic transfusion when my special needle is used[3] and therefore this should be the route of choice

[3] Haxton H A *Lancet* 1953 i, 622.

The evidence from animal experiments and clinical trial is now overwhelmingly in support of intra-arterial transfusion as the only measure which will save life in cases where shock from hæmorrhage is of sufficient severity and duration It is sad, therefore, to think of the many lives lost every year which could probably have been saved by this measure It is surely not too much to hope that soon every hospital of any importance will have the equipment for intra arterial transfusions and staff who are prepared to use it

Manchester

HERBERT HAXTON

TATTOOS

SIR,—I have read with great interest your annotation last week on this subject However, it surprises me that you do not accord to viral hepatitis a place in the list of potential complications of deliberate tattooing carried out for purposes of adornment

Hobson et al[1] investigated this question among patients in a military hospital in Hong-Kong—a group among whom tattooing was popular and viral hepatitis prevalent They found that, out of 143 patients admitted with viral hepatitis during a certain period, no fewer than 56 (or 39 2%) had been tattooed between 51 and 150 days prior to the onset of the disease As controls, they took 152 patients admitted during the same period for other complaints In this group the number tattooed during the corresponding period was only 16 (10 5%)

They also describe the modus operandi of a local tattooist, their description lending eloquent support to the belief that the virus may be transmitted in this way

G A K MISSEN

TUBERCULOSIS

SIR,—May I answer the letters of Dr Paul and Dr Hoffstaedt (Oct 10)? Perhaps our differences are not o great as they appear, although it is necessary to correct npressions that may have been given concerning the control of tuberculosis in cattle It is true that bovine tuberculosis was virtually eradicated in the U S A 23 years after the inception of a nation-wide campaign in 1917, but at that time the over all incidence in adult cattle was only about 4%, compared with about 25% in Great Britain in 1935 Again, 16 years ago in Denmark 48 5% of all herds had been tuberculin tested and 26% of these were free from infection In Great Britain there was no effective scheme for the control of bovine tuberculosis until 1935, and owing to a Government decision no new attested herds were created during the war In 1944 there were only some 600,000 cattle in these herds By 1946 the number had increased to 1 million (about 13% of all cattle—i e, roughly comparable with the Danish picture in 1937) and by 1952 to 3½ million There are now some 4 million cattle in attested herds out of a total of about 9 million, so at the present rate of progress tuberculosis should be virtually eradicated in 10 or 12 rather than 34 years

To suggest that injection of the B C G strain of avirulent tubercle bacilli increases the incidence of bacilli in the population is rather like saying that vaccination increases the incidence of smallpox virus—although one admits that even this procedure has its opponents

Dr Paul still seems very unconcerned about the presence of virulent tubercle bacilli, and Dr Hoffstaedt even suggests that it would be unfortunate if we attempted to "banish from our shores a virtually ubiquitous and mostly quite harmless germ" "Mostly quite harmless" seems a strange description to apply to an organism that, as Rich says in the last sentence of his book on *The Pathogenesis of Tuberculosis*, still kills more than twice as many people as any other single cause of death during the particularly productive and enjoyable period between the ages of 15 and 45 He points out that increased genetic resistance cannot possibly be the sole reason for the precipitous fall in the mortality rate that occurred within a scant two generations Even if it were entirely responsible, Sir Macfarlane Burnet[1] has indicated that it would take centuries before resistance fell to that of, say, the American Indian

The elimination of most infectious disease doubtless tends to increase the susceptibility of the population, but few people think it desirable that we should continue to have a good infection-rate with such organisms as *Corynebacterium diphtheriæ* or *Treponema pallidum* If it were desirable to maintain tubercle bacilli in the population there would, of course, be no reason at all for public health doctors to worry about tubercle bacilli in milk, for, if one must be infected, the alimentary route is much less dangerous than the respiratory Mr L Pitcher has devoted much energy to attempting to show that as one eradicates tuberculosis from cattle the death-rate from pulmonary tuberculosis increases It is probably true that under certain conditions, which may have prevailed in Great Britain, tubercle bacilli in milk decrease the total death-rate from human tuberculosis, but Dr Daw[3] rightly questions Mr Pitcher's argument and asks for more evidence One may say briefly that the mortality from human tuberculosis has continued to fall steadily in the U S A since the virtual eradication of bovine tuberculosis This is also true in Tasmania and in Queensland (an area mentioned by Mr Pitcher as having a low human mortality and at one time high incidence of bovine infection) Above all, both human and bovine infection have been eradicated from the island of Bornholm

I agree of course with Dr Paul and Dr Hoffstaedt that a general improvement in living standards is probably the most important factor in reducing the mortality from tuberculosis Various predictions that tuberculosis would become extinct by a certain date through the operation of such natural causes have however been falsified, and it is salutary to remember that only 53 years after syphilis appeared in Europe Fracastorius wrote "Whatever may be the cause we must conclude that this disease has now entered its old age, and that the time is not far off when it will cease to propagate itself" As one would expect, the best results in the control of tuberculosis have been achieved when specific attempts to prevent the spread of tubercle bacilli have been combined with good living conditions, and the mortality rate is now below 10 per 100,000 in Denmark and in certain States in the U S A, and is only 11 per 100,000 in Tasmania

Dr Paul suggests that I am confusing the eradication of tuberculosis with the eradication of the tubercle bacillus In an essay on the Natural History of Tuberculosis Sir Macfarlane Burnet[1] wrote "To prevent disability and death from tuberculosis the one outstanding requirement is to prevent primary infection with the bacillus" Or, as Sir John M'Fadyean wrote in 1901, "all efforts must be concentrated against the one great cause of the disease—the operation of contagion" Myers has said much the same thing on many occasions, but it would seem that the truth of these statements cannot be too often emphasised Sir Macfarlane's essay no doubt influenced the scheme for the control of tuberculosis in Tasmania, and if he reads it Dr Paul may discover some alternatives to the method of slaughter Incidentally we have eradicated tuberculosis from 40% of our herds without slaughtering, for this purpose,

single unoffending cow, although our failure to do so has annoyed a good many people

When in 1895 the use of tuberculin had revealed the high incidence of bovine tuberculosis in Great Britain it was concluded that any attempt at eradication was quite impracticable It was true that sudden radical measures were impracticable and nothing was done for some 40 years during which time the incidence of infection remained nearly constant but as soon as the community decided it would try to eradicate the bovine tubercle bacillus it was found that steady progress could be made, and eradication areas have now been established I realise that eradication of human infection is a far more difficult and complex task, but let us agree that the presence of virulent tubercle bacilli in the human population is as undesirable as it is in cattle It may then be found sooner than some people expect, that improved living conditions allied with specific measures against the tubercle bacillus, which I am sure would have the support of Dr Paul and Dr Hoffstaedt, have reduced the incidence of infection to such a low level that virtual eradication is not an impossibility It is a matter of fact that good progress towards eradication of the tubercle bacillus has been achieved in several communities without apparently exciting any serious opposition

CONTROLS

SIR —It is a matter for regret that the use of normal children (or children suffering from some irrelevant disease) as controls in clinical research appears to be increasing

No medical procedure involving the slightest risk or accompanied by the slightest physical or mental pain may be inflicted on a child for experimental purposes unless there is a reasonable chance, or at least a hope that the child may benefit thereby

If this is true—and I hope that there are few doctors in this country who would disagree—then it must surely be difficult to justify the use of two hydrocephalic infants reported in the paper by Dr Doxiadis and his colleagues, and the use of a normal control by Dr Bickel and his colleagues Both papers appeared in your issue of Oct. 17

It may be of course, that there were some good reasons for the use of these children which have not been made clear If so, the authors owe it to themselves to explain

London, N 1

R E W FISHER

*** Dr Doxiadis is now abroad, but we have shown the above letter to the other medical authors of the two papers. They reply as follows

'It is quite reasonable that Dr Fisher should raise the question of the use of normal children or children suffering from some irrelevant disease as controls in clinical research There are extreme opinions on both sides, but I feel most of us adopt a policy between the two—somewhere in the grey between the rather theoretical white and black My own working policy which differs slightly from that expounded by Dr Fisher in the second paragraph of his letter is that no procedure should be carried out involving risk or discomfort without a reasonable chance of benefit to that child *or other children* and this principle was followed throughout our work. The crux of the matter is contained in the last sentence of Dr Fisher s letter—we owe it to ourselves to explain our actions Surely we all weigh these matters most carefully in our own consciences. —K S. HOLT

We are grateful to Dr Fisher for raising a problem of which we are fully conscious in our daily work Nevertheless errors of metabolism constituting the underlying cause of many diseases cannot be understood or properly treated without knowledge of normal physiology With regard to our own work phenylalanine is an essential article of the diet, and Rose [1] recommends a daily intake of 2 2 g Earlier work on normal adults [2,3] and on children [4,5] has shown that considerably larger amounts of phenylalanine may be ingested, as they are rapidly metabolised and cause no untoward effects. Our work was undertaken to observe the blood levels of a normal child after doubling the normal phenylalanine intake in order to compare the normal tolerance curve with the pathological curve in phenylketonuria. This may be regarded as closely comparable with a glucose-tolerance test in that it is both harmless to the normal and of great importance for the assessment of pathological curves ' —H. BICKEL, J GERRARD

BASIC GROUP PRACTICE

SIR —We have followed, with great interest, the series of articles on general practice which have appeared from time to time in *The Lancet* under the name of Joseph S Collings We have been impressed with the tireless energy he has displayed in pirouetting round this country studying and reporting on individual practices and issuing reports on how general practice *really* ought to be conducted. Then we read in his article of Oct. 24

> In its first five years the National Health Service has done little to stimulate the development of group practice Hopes were centred at first on the possibilities of ill-defined and little understood health centres ; but these hopes have only been fulfilled in two or three places and by now have lost their charm both for the general practitioner and for the Exchequer They are monuments to the local authorities and the outcome of a do nothing policy in regard to the main structure of general practice '

Such ex-cathedra statements are rather mischievous particularly when we know that Dr Collings has never taken the trouble to visit the William Budd Health Centre in Bristol to find out what progress has been made

If he is so ready to condemn health centres which as yet have had little chance of proving themselves, and even without any first-hand knowledge of how at least one of them is working then we fear we must reconsider our judgment of the value of his previous articles

Bristol.

R C WOFINDEN
J SLUGLETT

PERIODIC MEDICAL OVERHAUL

SIR,—Sir Adolphe Abrahams generalises against periodic overhauls on the basis of three cases, although undoubtedly he could cite more Surely no-one in medicine, least of all Sir Adolphe with his vast experience, would suggest that any examination, advice or treatment was likely to be 100% successful in all cases.

What does Sir Adolphe mean by sensible people ? As regards health few people are sensible. Has he never met any people, even doctors who have had headaches, indigestion piles, or a cough for months and who have never done anything about it and eventually been found to be severe hyperpietics or to have inoperable carcinoma or advanced pulmonary tuberculosis ? Admittedly many of these people would not have a periodic overhaul anyway but the whole idea of such a check is to try and catch *some* of the early cases of tuberculosis, carcinoma, anæmia hyperpiesia, diabetes, &c explain what is wrong and help them to be relieved or cured before they become invalids

There are difficulties in that few even intelligent, people will give the time to have an overhaul or they are scared of the possible result and the doctors in the National Health Service have not got the time or the facilities to do their job as they would wish

5 Levine S Z. Dann M., Marples E. *J clin. Invest.* 1943 22 551

Those of us who have the time to take a proper history, carry out a detailed examination of the patient, and talk to him afterwards, know that hardly a day passes when someone is not found with some complaint which can be cured or at any rate ameliorated in its early stages and thereby save him a great deal of discomfort and possible anxiety in the future

Finally, if not the doctor, who would Sir Adolphe suggest is the best person to give common-sense health education ?

Hook, Hampshire R H SCOTT

POSTURE, BACKACHE, AND HEALTH

SIR,—In his letter of Oct 17, Mr Tucker describes an ideal posture and guarantees that if one learns to stand in this way *continuously* one never seems to grow tired Many different postures have, in the past, been advocated as ideals and their theoretical mechanical advantages have been described, but, as far as I am aware, little practical evidence has ever been produced to show that any of them have, per se, any influence on the incidence of postural disorders of the supporting tissues

Posture is the sum of the conditions pertaining at all the joints of the body In the majority of those postures which are regarded as bad, poor, or abnormal, no joint is outside its normal range of movement The crux of the matter therefore seems to be, why joint positions which can be utilised with impunity in some circumstances become fraught with danger to the joint tissues if utilised in standing

Joint tissues, although they are living tissues, conform, in their reactions to stress to the same physical laws as inanimate objects such as steel or rubber All the tissues which may be involved in maintaining the position of a joint —namely, bone, cartilage, muscle, ligament, and fascia— all these tissues are elastic to momentary stresses of a magnitude less than the breaking load each is deformed when stress is applied to it and recovers its original dimensions when the stress is removed On the other hand, these tissues react in a different way to *prolonged* stress A stress which is less than the breaking load will, if it is allowed to persist for longer than an optimum time produce a gradual progressive distortion of the tissues Moreover, part of this distortion will be permanent unless it is slowly corrected by a vital reaction within the tissues

In standing, the stress on any joint tissue is never as great as the breaking load, and it is therefore only the duration of the stress and not the stress itself—only the duration of the posture rather than the posture itself—which can cause permanent changes in the joint tissues In other words a posture which is maintained continuously for a long time will damage the supporting tissues irrespective of whether it is regarded as an ideal posture or a bad posture, whereas any posture into which the body can be painlessly moulded will be harmless if it is of a short duration

The work of Ingelmark and his colleagues[1] has suggested that the time factor may also be important in another way They have produced considerable evidence in support of the hypothesis that the nutrition of articular cartilage and the production of synovial fluid are, in part at least, dependent on the rhythmical compression and release of articular cartilage A corollary to this hypothesis is that continuous compression of articular cartilage by the continuous maintenance of any posture would adversely affect both these functions

Observation of people in the street or of any person who is unaware that he is being watched shows that natural standing (in contrast to that of a soldier standing at attention) is never a continuously immobile act A person stands still for a short time, then shifts his lower limbs pelvis, and trunk before becoming still again for another short period, and this alternation between movement and immobility continues throughout the stance The average duration of the immobile periods is only about thirty seconds.[2] Moreover, not only is the continuity of the stress on joint tissues repeatedly broken in this way, but different postures may be assumed during successive immobile periods, so that the tissues on the right and left sides of the body are alternately subjected to the greater part of the total stress

Because the method of normal standing is so much in keeping with the physical properties and physiological processes of joint tissues, it seems reasonable to suggest that aberrations of the normal periodicity of standing might have a closer causal relation to postural disorders than the form of the various postures which are adopted during that act It was observed in the course of the investigations quoted above that in a small proportion of the subjects studied each immobile period of standing was prolonged beyond one minute I feel it would be of interest if the incidence of such habitual prolongation of the immobile periods of standing could be correlated with the incidence of postural disorders

COARCTATION OF THE AORTA

SIR,—We have read with great interest your excellent editorial (Oct 24) on this subject, and there is one point upon which we should like to comment

You say that direct aortography should always be used in the preoperative investigation of coarctation. This investigation, although undoubtedly more precise and informative than venous angiocardiography, is not without risk, principally because of the high concentration of dye which enters the cerebral vessels and the coronary arteries In addition, the retrograde route involves the use of a peripheral artery, and intubation of the main artery to one upper limb, with the risk (admittedly small) of subsequent arterial thrombosis and ischæmia of the limb Positioning of the catheter in the arch of the aorta is not as easy as it may sound, and in short the investigation is usually far more time-consuming, difficult, and hazardous than angiocardiography by the venous route.

In our experience, venous angiocardiography gives an adequate picture of the site and extent of the coarctation, of the aorta above and below, of the origin of the left subclavian artery, and of the collateral circulation in the majority of cases[1] The risk is very small indeed but sufficient contrast medium must be used (1-1 5 ml of 70% diodone per kg body-weight) in order to obtain a good result We believe that aortography should only be performed in cases in which venous angiocardiography has been inadequate, or in which special problems of diagnosis exist, or when the surgeon expressly requests it

J F. GOODWIN
R E STEINER

SIR,—You say in your leading article (Oct 24) that no entirely satisfactory explanation has been found for the dilatation of the vessel so often noted distal to the constriction You mention the defective structure of the aortic wall as a factor, but perhaps the most important cause of dilatation of this segment is the turbulence which must invariably be created there. While, from above, we have the blood passing through the narrowed part of the aorta under high pressure, below the constriction we find, as a result of the collateral circulation, a retrograde flow from the intercostal vessels into the distal segment, again at a pressure only slightly lower than that in the proximal part of the aorta Even when the coarctation is complete, as it rarely is, the blood-flow from the intercostals into the aorta must create a considerable amount of turbulence, and it would be surprising if some dilatation did not result The position ght perhaps be compared to the post stenotic dilata n associated with aortic or pulmonary stenosis, again bably the result of turbulence created in these vessels the blood flow through the narrowed orifice

---

[1] Goodwin J F Steiner R. E Mounsey J P D, Mac A. G, Wayne, E J *Brit. J Radiol.* 1953, 26, 161

The late systolic murmur usually heard in coarctation the aorta is often attributed to increased blood flow ough the collateral channels, and to kinking of these sels. The murmur cannot be due to the blood passing ough the constricted part for obstruction may be nplete at this point That turbulence in the distal ment of the aorta plays a part in the production of murmur seems likely and it may indeed be the rce of this characteristic physical sign

ublin. **Risteárd Mulcahy**

THE FACE IN DIAGNOSIS

IR,—Mr StKatsareas's article last week (p 920) ntions an astonishing number of facial signs, but enture to suggest that two or three more conditions causes of conditions, might be included.

diagnosis of argyria of the face has sometimes n discounted because no possible cause for the deposit ilver could be found

remember an instance in question: a young woman her doctor were unaware of any possible cause for the mentation (a biopsy of the skin had not been made) l the patient produced an old prescription from another tor who had ordered pills containing silver nitrate for "indigestion. So successful were the pills that the lent continued to take them whenever she had indigestion her similar cases have probably occurred from time to time case was shown at one of the annual meetings of the ish Association of Dermatology in which there was con rable facial pigmentation of the argyria type but no sible cause could be found My attention had recently n directed to the occasional occurrence of facial argyria to the use of a lotion containing Argyrol for the treat- nt of sore throat The general public was not aware hat time at any rate, that argyrol was a silver preparation questioning the patient admitted that he had been using outh wash or gargle for the throat. His doctor wrote he a few days later to say that on going further into the he had found that the patient had used a prescription taining silver nitrate

number of other conditions might be included

here is a possibility of pigmentation of the face being ed by the internal use not of silver but of bismuth.[1]

facial jaundice is included I think that yellowness of face due to hypercarotinæmia might also be mentioned his condition the sclerotics do not share in the yellowness hey do in true biliary jaundice

nequal pupils resulting from neurosyphilis are of course tioned among the important facial signs. But the ual pupils forming a part of Adie's syndrome (or Markus's drome)[2] have not been included

he "ecchymotic mask, due to accidental violent com sion of the chest wall is beautifully illustrated in French ical literature If the patient survives, I believe the l ecchymoses completely disappear

ethæmoglobinæmia or sulphæmoglobinæmia sometimes e a ghastly tinge to the face but these conditions are not n encountered

he telangiectases of the Rendu Osler type of telangiec may not be obvious in some cases

characteristic examples of Bourneville's disease (tuberous rosis) the tell tale so-called Pringle's nævi (telangiectatic ceous adenomata) grouped about the nose are very king

he combination of the facial vascular nævus with buph lmos ("ox-eye) on the same side and hemiparesis on opposite side of the body is seen in classical examples of the ge Weber Kalischer syndrome

scar in the parotid region associated with flushing and ating on the same side of the face is the least ommon type of the auriculo temporal and allied dromes.[3]

arkes Weber F *Proc. R Soc Med* 1933, 26, 60

arkes Weber F Rare Diseases and Some Debatable Subjects. London, 1946; pp. 59 66

The presence of even the slightest xanthelasma of the eyelids may I think, sometimes have an important significance because of its occasional association with xanthomatosis of other parts of the body and with grave atheromatous lesions of the cardiovascular system

London N W 1 **F Parkes Weber.**

SIR,—As a non medical reader of the *Lancet* I feel impelled to congratulate you upon Pierrhos StKatsareas's article which has the true note of Sir Thomas Browne in many sentences But alas! that you should speak of Alcmene's nights instead of Alcmena's True that mean ale may make for misery but I believed that you knew Sir Thomas Browne by heart

London S W 1 **F Sherwood Taylor.**

SPUTUM IN CHRONIC BRONCHITIS

SIR,—We should like to comment on the article by Dr Elmes and his colleagues last week

In hospital we see for the most part, the patient with complicated chronic bronchitis. By that is meant chronic bronchitis with emphysema, with right ventricular hypertrophy with congestive cardiac failure, with cerebral anoxia, or in patients acutely ill from a respiratory infection. In other words we begin and end with a respiratory cripple, unemployable or only employable in a limited capacity Dr Elmes's cases are no exception

To pursue the prophylaxis of acute respiratory infections in chronic bronchitis, one would have to enlist the aid of the general practitioner who sees bronchitis in its early stages. The College of General Practitioners could with outside expert help tackle this most important problem The general practitioner in an industrial area (where bronchitis is most prevalent) is very busy in the winter so the antibiotic would have to be given by mouth and here we would plead for chloramphenicol, which is condemned by Dr Elmes and his colleagues We have used it ever since it became available and have not encountered any toxic effects. We give it in divided doses of 2 g daily for not more than six days Its effect in clearing *Hæmophilus influenzæ*, the really awkward infection in our experience, is dramatic We are sure that it has been responsible for saving many lives It does occasionally produce diarrhœa, but this seldom lasts for more than twenty four hours Aureomycin on the other hand can cause distressing diarrhœa and for this reason we have abandoned its use unless it is specifically indicated.

We wonder whether respiratory infections are a major factor in making a respiratory cripple of a chronic bronchitic What about cough and smoking? Is not a mucoid sputum with its attendant cough more injurious over the years than respiratory infection each winter? These infections do not usually by themselves, cause death until later in the disease when the patient no longer has uncomplicated chronic bronchitis In our efforts to eradicate the pathogens from the respiratory tract, it would seem probable that, in the course of a time, the bacterial world will develop a new armour and we will be caught up in the endless game of antibiotic versus bacterium Therefore, whilst not denying that the prophylaxis of the respiratory infection in chronic bronchitics is a most desirable objective surely we must if we are to produce any lasting benefit for these patients, concentrate more on the origin social aspects, and morbid anatomy and histology of the disease We might then be able to define what we mean by chronic bronchitis!

Finally we should like to congratulate Dr Elmes and his colleagues on their thoughtfulness in selecting patients who could attend daily without financial loss The chronic bronchitic comes mainly from the lower income group and in our clinic we make sure that pay is not lost because of the visit

GASTRIC RESECTION FOR HÆMORRHAGE

SIR,—Mr Gordon Ferguson (Oct 10) raises the problem of the correct procedure when no cause is found at laparotomy performed for recurrent hæmatemesis and melæna These cases are usually due to acute gastric ulcers which are impalpable at operation The follow-up of acute gastric ulcers, causing bleeding and diagnosed gastroscopically, gives a clue to the best surgical procedure In men there is a big proportion who subsequently return with chronic gastroduodenal ulcers, and partial gastrectomy is therefore reasonable at a time of brisk and repeated bleeding when no obvious cause has been found, but the surgeon is well advised to inspect the remaining part of the stomach before completing the operation In women the follow-up of acute ulcers is excellent, few returning with chronic ulcers, but there may be further episodes of bleeding [1]

We believe the best procedure is that described by Mr G L Bohn, of Reading He opens the stomach and not only inspects the mucosa for the acute ulcer but palpates for the exposed vessel which may feel like a small hard shot through the rubber gloves Having located the vessel, he then performs an intragastric submucosal resection of the ulcer In this particular group of patients, we think this is a very valuable technique Where available, gastroscopy can be a real help in locating small bleeding ulcers in cases which may require surgery Bleeding tends to recur at intervals of 12–24 hours, and it is sometimes possible to choose a time when bleeding has stopped and when the stomach is empty

Department of Gastroenterology,
Central Middlesex Hospital,
London N W 10

F AVERY JONES
J W P GUMMER

SIR,—In his article on gastric resection for gastroduodenal hæmorrhage without an obvious ulcer, Mr Ferguson mentions the inadequacy of the inspection of the stomach made possible by gastrotomy

May I, in this connection, recall that many years ago Rovsing, in Copenhagen, on such occasions used the simple expedient of introducing a small lamp through the gastrotomy and inspecting the transilluminated stomach wall He stated that by this means the bleeding vessel could be easily found by the interruption in its course, which could be clearly seen He became cautious about the procedure because of some accident with an electrical short-circuit, but this should be avoidable with modern equipment—possibly low-voltage lamps

Medicine and the Law

Professional Negligence An Unsuccessful Appeal

LAST March a widow was awarded damages in her action against two dental surgeons on the ground that their negligence in the professional treatment of her husband had caused his death One of the defendants extracted teeth from the patient's mouth while the other administered the anæsthetic Somehow the patient swallowed or inhaled a throat pack which had been inserted in his mouth, and asphyxia resulted At the trial the judge took the view that the facts indicated negligence and that it was for the defendants to rebut that indication The Court of Appeal has refused to interfere with his decision [2] The appellants contended that the occurrence was an unfortunate mishap of an extremely rare kind which could not reasonably have been foreseen, the fact that it happened was no proof of negligence Lord Justice Somervell rejected this contention It had been argued, he said, that the two dental surgeons had followed the usual practice of their profession and that a series of highly impr coincidences had caused the patient's death. But was ample evidence to support the finding reached trial court that the throat pack had been too This, said the Lord Justice, called for an and the defendants' attempted explanation had broken down Lord Justice Denning, concurring that the accident was one which could and have been avoided, the fact that a similar had never happened previously was really som which told against the defendants The appeal dismissed and leave to appeal to the House of L refused

It is familiar law that a medical or dental practit while he owes the duty to use reasonable skill and does not guarantee successful treatment any more a lawyer guarantees to win his client's case. not responsible for an accident which could not ably have been foreseen Where the line should drawn—what degree of care and skill is reasona is a question depending on the circumstances of each The ruling of the Court of Appeal, disturbing th it may appear, need not be taken as altering the ge principles of professional liability What is neg and what is an accident will still have to be deci the light of the particular facts established in evidence

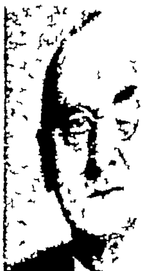
Obituary

WILLIAM NORWOOD EAST

Kt, M D Lond, F R C P

Sir Norwood East, a former Commissioner of P and a director of the Prison Medical Service, died home at Crowthorne, Berks, on Oct 30 He retired active work in the prisons in 1938, but his coll will find the Prison Medical Service strange without for he had never ceased to attend conferences, both and informal, and they had continued to rely on wisdom, experience, and sympathy

He was born in London, on Christmas Eve, 187 son of Mr W Quartermaine East, D L and he educated at King's College School and King's C



He qualified from Guy's Hospital in 1897, and two years later he joined the Prison Service as a medical officer He held appointments at many of the larger prisons before he was appointed senior medical officer at Brixton Prison in the early 'twenties The work of a senior medical officer at Brixton involved spending many days in court, not only at the Old Bailey but in assize towns in the Home Counties Much of the day to day work at the prison had to be done in the evenings after return from court, but East never spared himself His reputation as an expert witness stood high, and he would spend long hours taking a history from a man on mental state the court had asked for a report

In 1924 he became Medical Inspector of Prisons he brought to the Prison Commission a capacity which has seldom been equalled He the provision of an up-to-date operating-thea Wormwood Scrubs Prison, so that major surgical tions could be carried out within the prison, and started the prison nursing service with State-reg nurses He became a Prison Commissioner in 193 he was also appointed director of the Prison Service

Retirement in 1938 brought him little relaxation his hard work He continued to be one of the d appointed by the Home Secretary to inquire into mental state of prisoners on whom the capital had been passed These inquiries often involved journeys at short notice with an exacting and re duty at the end of the journey He also conti ture in forensic psychiatry at the Maudsley Hospital dical School

Ie was an effective and lucid speaker and an active mber of the societies of his specialty and in due rse he presided in turn over the Society for the Study Inebriety and Drug Addiction (1940–45), the psychi ic section of the Royal Society of Medicine (1948) and Medico-legal Society (1945–47) In his books and ays East also made a remarkable contribution to his cialty *Forensic Psychiatry* (1927) is a useful guide doctors called to give evidence in the courts on mental cases. *Medical Aspects of Crime* (1930) is a collection thoughtful essays. In *Psychological Treatment of Crime* 39) he and the late Dr W A. de B Hubert described ir investigation into the psychological treatment of minals and recommended that a special establishment hin the Prison Service should be provided to deal h psychopathic personalities and other psychiatric es. One of the last occasions on which East attended Prison Commission was at a meeting to discuss the nning of this establishment But the start of this ject has been much delayed by post war conditions *ciety and the Criminal* (1949) is another collection essays which he described as some of the stepping nes over which I have travelled towards a better lerstanding of crime and criminals'

C W M recalls that East came as senior medical cer to Brixton Prison from Liverpool Prison with the utation of being a formidable personality and a hard rker

We juniors were told we were in for a strenuous time der him We found him strict but fair and without doubt remendous worker He helped and encouraged us all he ld and from him we learned much. Many young dical officers owe their successful careers to him, and I had the privilege of succeeding him as medical com sioner know it was not only his colleagues he helped ny ex prisoners owe a great debt of gratitude to him for was blessed with sympathetic understanding of their knesses and difficulties, and helped many to overcome m. At the end of his last book he bids those who follow 'be faithful to scientific standards and earn the respect his colleagues East was certainly faithful to scientific ndards and he earned the respect of his colleagues.

J L. writes: Norwood East cannot be replaced psychiatry like his social and moral convictions, solid and simple free from the complex uncertainties t now harass us

This simplicity was not the outcome of unawareness or defect of penetration and grasp With an unrivalled y of experience at his call and an exceptional knowledge he literature of his subject he could give a sure empirical gment on any practical question of forensic psychiatry a wisely critical survey of theoretical issues such as ability His unassuming integrity sense of duty and spoken opinions went with a humane regard for individuals a concern for their betterment which was reflected in advocacy of the therapeutic penal institution He had time for cant or sentimentality he detested vapid excuses criminal behaviour and he had a strong sense of things ible; but he fought with courage and determination what he thought should be done to improve our under ding of the delinquent and our capacity to help him His arch was characteristically thorough and cautious his ting, like his conversation pithy and unequivocal About research he was needlessly modest; his contribution to study of adolescent offenders is a monument that will d. Teaching gave him keen pleasure and he prized the ortunity greatly During the thirty years he lectured the Maudsley he was unremitting in attendance and ful preparation; he gave his last series of lectures only months ago and was lucid and vigorous as ever with extraordinary case memory fully at his disposal.

Looking back, one recalls his slightly formal courtesy humour his genuine respect for the work of others and ove all his outstanding honesty of mind and steadiness of pose Whose life was distinct and in Method and his ions as it were cast up before A man firm and standing his purpose nor heav'd off with each winde and passion that thinkes what he does and does what he sayes, and sees what he may doe before he purposes. A man well d in all humours, in whom nature shew'd most Geometry the has not spoyl'd the Worke

EMMA CHRISTINE PILLMAN-WILLIAMS

M.B.E., M.A. Camb., M.B Lond

Mrs. Pillman Williams chemical pathologist to the Royal Free Hospital, died at her home in London on Oct 28

She came of an old Devonshire family and she was educated at Sidcup and Blackheath High Schools and at Girton College Cambridge where she took the natural sciences tripos specialising for her part II in physiology From Cambridge she went in 1910 to the London School of Medicine for Women After qualifying in 1914 she held house-appointments at the Royal Free Hospital where she later became assistant anæsthetist In 1916 she was seconded to the Ministry of Munitions as chief medical officer at No 7 Filling Factory Here she collected the material for her first paper, which dealt with the aplastic anæmia developed by trinitrotoluene (T N T) workers For her work at the factory she was appointed M.B.E

In 1919 she returned to the Royal Free and its medical school and she worked there till 1923, with a grant from the Medical Research Council, on the chemical changes in blood and urine during pregnancy The importance of these early investigations, and indeed of much of her later work was not fully appreciated for she had little gift for exposition and would sum up the research of years in a paper so condensed that it was barely comprehensible From 1923 to the outbreak of the late war she worked in what became the chemical pathology department of the hospital During this time her interest turned more and more to nutrition and dietetics and with Dr Dorothy Hare she studied the treatment of rheumatoid arthritis by a diet of raw fruit and vegetables with first-class protein and some fats. A film showing the remarkable improvement obtained in some severely crippled patients is still in existence but here again a full account of the investigation was never published Mrs. Williams was an advocate of this diet for people in general. From their early youth her family was brought up on a modification of it, largely prepared by her own hands and the physique of her sons in her opinion put Q.E.D to her theories of dietetics. She was a staunch and critical supporter of the Food Education Society

During the late war she was on whole-time service at the base hospital of the Royal Free at Arlesey but she returned to London in 1940 and was appointed senior lecturer in charge of the department of chemical pathology a post which she held at the time of her death

L. W writes I came late to medicine and it was as a student that I first appreciated Christine Williams's outstanding characteristics—her all-embracing kindness and her interest in her fellow men. It was only her incredible energy and her will power that enabled her to pursue her career while bringing up her family of four outsize sons With her Swiss Family Robinson bag Piller as she was called by her friends was an essential part of the hospital colleagues, residents, nursing staff students, patients all came to her for help and she never failed to respond For every ill there was always a vitamin! She kept open house, first at Cumberland Terrace and later at Harley Street a party of fifty lads for the night was taken in her stride At Arlesey her hospitality her personality and her determination to get on with the job did much for the morale of staff and students alike Her patients adored her and would report for years after their discharge knowing that help and advice would be theirs. In fact everyone came to Christine and I used to describe her as the most imposed-on individual in the hospital Generous to a fault, she would cheerfully give her all and go hungry and in rags. In her youth she was fascinating and pretty with a milkmaid's complexion in later life she still charmed in her famous twenty year-old Paris hat

In 1919 she married Dr Ulysses Williams radiologist to the Royal Free Hospital. There are four sons of the marriage

Notes and News

FROM CARE TO CURE

ON Oct 28 the Duke of Edinburgh visited Goodmayes Hospital, Essex, to see something of its work Speaking at a luncheon afterwards he said "This hospital interested me as an individual, because it is seeing what is really the beginning of a revolution—the revolution from care to cure It strikes me that it must be a source of very great satisfaction to doctors and nurses in this service to know that they are making or doing a positive good in the healing of the mentally sick This is a satisfaction which the rest of the medical profession have had for a very long time but which for the mental health service has only really begun to start"

Mr Iain Macleod, the Minister of Health, said that when it was known that the Duke of Edinburgh wished to visit a mental hospital it had seemed sensible to invite him to one where the staffing situation came somewhere between adequate staffing and an acute shortage, to choose a hospital where overcrowding was neither negligible nor formidable They wanted to show him a hospital where good work was being done in old buildings Goodmayes was typical of many other hospitals of this kind—neither the newest nor the oldest which were "the county regiments of the Army" of those who served in the mental health field

THE HOSPITALS YEAR BOOK

FOR a reference book familiarity breeds affection rather than contempt, and friends of the *Hospitals Year Book*[1] will be glad to find the 1953–54 edition its usual informative self But Mr J F Milnes, the editor, shows discrimination in his respect for tradition and he has sensibly dropped the detailed bed and patient statistics, now largely available in the Ministry of Health's *Annual Review of Hospital and Specialist Services* Thanks to this saving of space he is able this year to give us details of mass radiography units, and to provide a separate index to special hospitals The index to statutory instruments, memoranda, and circulars has been expanded to include N H S Whitley Council circulars and there is also a short bibliography of books and reports about hospitals

SURVIVAL OF CASTAWAYS AT SEA

IN peace time 50,000 persons a year die as castaways, 90% of them from despair in the first three days Dr Alain Bombard[2] believed that a castaway need not die of hunger ("there are nearly two hundred times as many living organisms in a cubic foot of water as in the same amount of earth"), or of thirst (provided his kidneys are healthy an average man can drink with impunity $1^1/_2$ pints of sea water a day), or from despair (because survival is feasible) He read all he could about shipwrecks, the experiences of survivors, the chemical composition of fish and how to catch them, and winds and currents, and he experimented with plankton for food He then set out to prove his case

After a preliminary canter in the Mediterranean Dr Bombard drifted alone for 65 days in an 18 ft inflated rubber dinghy from the Canaries to Barbados For vitamins A, B, and D he relied on fish, and for vitamin C on plankton For water he used the sea and pressed fish He took emergency rations but never opened them He took no sun glasses, but he did take a sextant, fishing tackle, a small parachute to serve as a sea anchor and as a net for plankton, and a small sail, whose most useful functions were catching the rain and acting as a shelter from the sun He recorded daily his blood pressure, his temperature, and the state of his skin, nails, hair, and mucosæ, he measured his urine, and noted his muscular strength and the number of stools passed Among other discoveries he disproved the fallacies that there are no fish away from inshore waters and that sea water is laxative After a month or so enteritis set in, but after 53 days he met a liner and had a small meal, which gave him the worst stomach trouble of the whole voyage but apparently cured his enteritis During the voyage his blood pressure varied with his state of mind, both being depressed together, the meeting with the liner restored both to normal After leaving the liner he continued for another 12 days before landing in Barbados By this time he had lost 55 lb in weight and 2 500,000 red cells per c mm of blood, but he showed no signs of
deficiency

It may be objected that whereas Dr Bombard was used to roughing it at sea, other castaways might to seasickness or be otherwise incapable of keeping th alive as he did But by enterprise and endurance he ha his point and has made it in a way that must cause attention to be given to the needs of survivors from th

BEER BY THE REED

SOME take their vitamin B in wholemeal bread, the husks of their rice, some buy it in a pot or a have it for breakfast, but the 16,000 inhabitants of Island, in Lake Victoria, take it as—and at—a beer The island measures 30 square miles, and when decides to hold a beer drink everybody, in theory, can Fortunately only about 200–400 of the nearest usually turn up

Dr Hope Trant, who describes one of these social in the East African Medical Survey Annual Report[1] says, that the men arrive first, usually at about 4 P.M., carrying a drinking reed, and most of them bring own stools Those without stools look round for sit on, if necessary supplying themselves from the foundations of the huts Meanwhile the men of the hou which is offering the beer are boiling up water in aluminium saucepans, called sufurias, which have used to make the porridge for dinner They have not washed since, so the water is nourishing and scummy

The beer itself is already prepared and stands in large earthen pots The recipe for brewing it is complex, and by our standards original

> First take a measured quantity of red sorghum (Guinea corn) and put it in a large wooden trough, add water for eight hours Mix with ashes and spread on a flat rock with grass and leave for 1–2 days to germinate When begins, wash to remove ashes, dry in the sun and grind known as *kimela* Place flour in the trough and mix with leave 3–4 weeks, turning with a wooden shovel every 2 or Next shovel on to a corrugated iron sheet and heat over turning with a wooden shovel all the time until it is hard blackish lumps like small pieces of coke Complete in the sun This product is called *kongo*, and will keep
>
> Repeat the recipe for making kimela, but using millet of sorghum. Measure out equal parts of kongo and millet Put a little of the millet kimela into the bottom of an ware pot, and add a 4 gallon tin of kongo mixed with water for 36 hours Mix the remaining millet kimela with water to pot containing kongo ferment. Leave for 4 hours, when will be ready to serve It is pinkish, tasteless, and heady

The visitors, while waiting for refreshment, groups and talk at the tops of their voices or draw water from the sufurias through their reeds, to that they are not blocked by the dregs of earlier As the scummy water comes to the boil they begin to round various hollows in the ground where the beer are to be placed One of the family comes along with deepens the holes, which are about 2 ft deep and Now the seats are placed round the holes until about 50 people, in three or four rows, round each talking loudly, with their tall reeds, tipped with forated tin cones which act as filters, pointed like the sky These reeds may be as much as 6 ft long, valued possessions, some are carried round, like in hollow containers, and extracted with pride and The longest reeds, as Dr Trant points out, are adapted to back benchers

Now the woven beer baskets, each capable of holding gallons, are brought along and patted into their pl the holes by willing helpers The hosts reckon that need 4 gallons for a 12 hour drink. Out comes the its 6 gallon earthenware pots, two staggering carried each, and someone thrusts his hand in to give the brew stir, his arm comes out coated to the shoulder with looks like bran mash The beer is poured sloppily, like gruel, into the baskets until they are half filled, and stage some rowdy spirits produce gourds and try to a little, shouts and cries from the other guests d this bad form The water boilers now arrive, carrying hot sufurias with bunches of green leaves, and the are filled to the brim for in Ukara beer is drunk warm diluted If there is not enough water to fill the bask has to be fetched from the lake and boiled, so waiting one's beer is a severe test of manners. Nevertheless ts (except perhaps an elder who may take a suck or two pretence of testing the flavour) until the host gives the al. It is a silent signal hard to detect but in a nent the reeds pierce the brown scum and the beer drink ns.

usually lasts, Dr Trant says, from 6 P M till 4 next ning and when the men have finished fresh hot water is red on the dregs and the women have a turn If there is ugh beer left over the same people come back next day finish it There is no drunkenness, however Those reach the swaying stage are discouraged from a further ion, and those who become too uproarious are sent home the end of the party everyone is able to walk home to bed riety is also favoured by the fact that sucking up beer ough a long reed is hard work

nly the chief and one or two headmen drink beer every but even ordinary people manage to get to a beer k about once a month A stranger has to pay 5s to headman of his area when he arrives, so that he will be epted as one of the family when he goes to a beer drink otherwise there is no charge This single entrance fee kes him welcome at all drinking festivities on Ukara.

eer making certainly uses up grain which might be kept food but on the other hand, its yeast content is an ortant source of vitamin B Moreover the inhabitants Jkara are exporters of rice and cassava; they can afford be a little extravagant in pursuit of their favourite eation.

MORE FLOWERS BY REQUEST

the long ago days when boating was the thing the ames lock keepers held an annual flower-growing competi n. Perhaps they still do At all events those always sunny mers are marvellously coloured and scented in memory their brilliant triumphs Country stations, too contend in way spilling lobelia and nasturtiums prodigally among coal-stacks, and training ramblers along the palings, to great refreshment of travellers Now the Worshipful npany of Gardeners and the London Gardens Society (20 kingham Street, W C 2) are striving to rouse the same ticultural spirit in the hospitals, beginning in a small way h the postgraduate and undergraduate teaching hospitals the London area. This year sixteen hospitals competed, l there is every hope that next year more will join in. perpetual silver cup presented by the company was won the Middlesex Hospital the silver and gilt medals, presented the society by St Luke's Woodside Hospital and the dsley Hospital respectively and certificates of merit by London Hospital and Queen Charlotte's

With this example before them other hospitals should pick their spades. The object of the competition is to encour the use of flowers *supplementary* to those at present usually nd in the wards, and the judges take into account not y the extent to which available open spaces are cultivated embellished and the decorative effect produced by ers in window boxes, waiting rooms, and corridors, but the skill of the gardeners in overcoming such drawbacks poor sites and little sun and the arrangement of plants provision for a succession of blooms On two unspecified es between April and October they call to see what is going Hospitals must thus keep on their mettle and not yield the gardener's temptation to murmur with Ruth Draper: ou ought to have seen it last week.

D O—J M. Ferries.

British Association of Physical Medicine

The annual meeting will be held at King's College Hospital, London, S.E.5 on Friday and Saturday April 30 and May 1

Germ free Life

We published last week (p 933) an account of the work of Prof J A Reyniers on the rearing of germ free animals Professor Reyniers described his technique and results at a meeting in London on Oct 15 arranged by Dr W P Blount poultry adviser to the British Oil & Cake Mills Ltd.

Myxomatosis

The Ministry of Agriculture and Fisheries report that myxomatosis has been found among wild rabbits near Robertsbridge in Sussex The area involved covers woodland of about 100 acres The disease was confirmed among rabbits near Edenbridge in Kent two weeks ago (see *Lancet* Oct 31, 1953 p 935) The *Manchester Guardian* (Nov 3) reports Prof G Ramon (Pasteur Institute) as saying that the disease has spread into Germany Belgium and Holland

Royal Appointment

Captain J B Oldham, R N V R, has been appointed an honorary surgeon to the Queen, in succession to Captain G McCoull, R N V R

Charterhouse Rheumatism Clinic

Dr J F Brailsford will deliver the Gilbert Scott lecture on Thursday, Nov 19, at 5 P M, at the clinic, 56, Weymouth Street, London, W 1 He will speak on the Prevention Detection, and Treatment of Osteo arthritis

Nichols Fellowship

The council of the Royal Society of Medicine invites applications for this fellowship, which takes the form of a grant of £225 per annum in aid of research in obstetrics and gynæcology Applications should be made before May 15 to the secretary of the society, 1, Wimpole Street, London, W 1, from whom further particulars may be had

Shortage of Resident Staff

The latest annual report of the Mansfield Hospital Management Committee expresses concern at the difficulty in obtaining resident doctors, particularly for the casualty and anæsthetic services The salaries paid to such doctors are " certainly no inducement to remain in the service longer than the 12 months' statutory period after qualifying " For many years, the report adds, the almost traditionally low salaries have been accepted, but now a new approach should be made to the question of the remuneration of young resident doctors

---

Dr Willi Hoffer has been appointed to the Abraham Flexner visiting lectureship at Vanderbilt University, Nashville, Tennessee

CTURER IN ANÆSTHETICS POSTGRADUATE MEDICAL SCHOOL OF LONDON

SINCE it was advocated by Flagg in 1928, endotracheal ygen has been used in many hospitals for the treatment asphyxiated newborn infants During the last twenty o years, however, so many other methods and appara ses have been introduced that it seems worth trying to aluate the technique of resuscitation as it has evolved Hammersmith Hospital, and to make some comparison our results with others which have been published may be said at once that it has not been possible to ow statistically that any one method is better than other This could not be done without a large ntrolled series a condition which presents almost superable difficulties in problems of this sort

In 1952 O Brien and Roberts, in a short communica m from this hospital, published the results of resuscita m by endotracheal oxygen of 65 asphyxiated infants, phasising particularly the satisfactory mental state the survivors We give our results here in greater tail, with an analysis of the cases by birth weight and d our experience during the last twelve months

The cases studied are those treated during the four ars from February, 1949 to the end of 1952 During e last year of this period three innovations have been ade in our treatment: immediate pharyngeal aspiration babies delivered by cæsarean section; gastric oxygen premature babies and the use of augmented piration whereby the infant s own respiratory efforts e assisted (Donald and Lord 1953) The place of these ethods in our routine is discussed

The study is entirely clinical. No pressure measure ents were made during intubation and the cases have en assessed without reference to X ray appearances, irometry or oxymetry

Endotracheal Oxygen

This method is generally accepted as an efficient means maintaining an airway and of obtaining some oxygena on of the blood by absorption through the bronchial ucosa. There is, however doubt about two aspects of e treatment, namely, its safety and its ability to assist tively in lung expansion Bloxsom (1951) stated that e risk of trauma is so great that tracheal catheterisa on is associated with a considerably increased mortality d that occasionally the lung or the stomach is punc tured; he recommended that the treatment should be bandoned THE LANCET (1951) described the pressures 5 cm. H_2O) as sufficient to allow bronchial absorption of ygen but condemned any attempt to promote lmonary expansion by blowing gases into the achea.

This condemnation springs from the customary state ent that, after attempted lung inflation those cases hich come to necropsy show distension of the bronchioli d alveolar ducts, with complete non-expansion of the lveoli. However, these are in fact post mortem findings when immature lung has been subjected to ante mortem inflation O'Brien and Roberts (1952) stated that the lungs of full time infants could be satisfactorily expanded post mortem, and we have since confirmed their findings in a full time stillborn infant intubated immediately after delivery Day et al (1952) using excised animal material, were also able, by using appropriate cycles of positive pressure to inflate the full time lung and to obtain expansion that was macroscopically and microscopically normal; they failed to expand by positive pressure the lungs of very immature fœtuses. It is therefore possible that endotracheal insufflation can help to expand the lungs of a full time infant, as well as providing oxygen and stimulating the stretch reflex of the lung

When an infant has been successfully revived with endotracheal oxygen it is impossible to estimate to what extent its lungs were expanded by its own efforts, and how much mechanical aid it received and to what areas of the lung The effectiveness of the method must be judged by the clinical improvement seen in individual cases, and from the over all mortality and morbidity figures

Method

This has already been described by Roberts (1949) and O'Brien and Roberts (1952) The following are the essentials

After a vaginal delivery as soon as the baby's head is delivered its mouth and pharynx are aspirated with an electrical sucker Since May 1952 immediate suction has also been used for babies delivered by cæsarean section, the extension from the electric sucker set at a vacuum pressure of 5 in Hg being to hand on the theatre trolley When delivery is completed, the baby is held up by its feet and subsequently nursed head low to promote drainage Where there is moderate asphyxia aspiration is repeated and a small metal airway (Waters no 00) is inserted The baby is next rocked in an oxygen box (Roberts 1949) If there is no response to this treatment within five minutes an endotracheal tube is inserted

In severe asphyxia where the infant is limp where there has been evidence of serious intra uterine anoxia or of aspiration of liquor intubation is performed immediately without preliminary rocking

With the help of a small laryngoscope a no 00 Magill endotracheal tube is introduced through the glottic opening until about $^1/_2$ in lies within the larynx and trachea. The tube is attached to a Y shaped metal connection and oxygen is supplied at $1^1/_2$ litres a minute through the smaller of the two arms If spontaneous respiration does not start the open end of the Y piece is occluded with the finger for not more than two seconds at a time and at the rate of 12–15 times a minute

If the tube becomes occluded with thick mucus it can be used as a sucker being withdrawn while a gentle negative pressure is maintained and then replaced if necessary. Thinner material may be aspirated through a fine Polythene tube passed inside the endotracheal tube

After a cæsarean section a single gastric suction [illegible] once respiration has been established (Gellis et a [illegible]

Gastric Oxygen

As described by Akerren and F[illegible] the administration of gastric oxygen may [illegible] the blood sufficiently to enable the [illegible] of the asphyxiated infant to recover and [illegible] respiration. We have no experience of gastric oxygen [illegible] full time infants, but we believe it is a [illegible] of the treatment for premature infants who [illegible] from complet initial apnœa

During the last year [illegible] insufflation [illegible] therefore been reserved for full time babies [illegible] larger premature babies. For small premat[illegible] gastric oxygen is used. This is administe[illegible] 1 mm. polythene tube attached by a [illegible] the [illegible] the oxygen [illegible]

Dr. Robert Hells Library
[illegible]

TABLE I—INFANTS INTUBATED

—	Survived	Dead	Total
Full time	42	3	45
Premature	18	9	27

0 25 litre a minute An underwater escape valve may be used No "outlet" gastric tube is necessary Stimulant drugs seem to be of some value if the baby is depressed by sedatives or anæsthetics administered to the mother Coramine 0 25–0 50 ml intravenously is used *

Results of Endotracheal Insufflation

In 1949–52 there were 7407 live births, and 72 infants were treated by intubation within a few minutes of delivery, 27 of these were premature (weighing $5^1/_2$ lb or less), and 45 were delivered at term (table I)

FULL TIME INFANTS

45 were intubated and 3 died In addition to these, 9 infants who died of asphyxia were, for various reasons, not intubated Details of the method of delivery are given in table II The majority were delivered by cæsarean section In 6 of the cæsarean-section cases and 2 of the forceps deliveries there was severe maternal pre eclamptic toxæmia

TABLE II—METHODS OF DELIVERY (FULL TIME INFANTS)

Method of delivery	Survived after intubation	Died after intubation	Died without intubation	Total
Cæsarean section	30	0	2	32
Forceps	6	0	1	7
Breech	1	1	0	2
"Normal delivery"	5	2	6	13
Total	42	3	9	54

There was thus a total of 12 asphyxial deaths in full-time infants out of 7407 live births (full time and premature) or 1 6 per 1000 live births The neonatal death-rate from all causes in the hospital during the same period was 21 7 per 1000, hence asphyxia in full-time babies was responsible for just over 7% of the total neonatal deaths Asphyxia was responsible for 12 out of 56 deaths in full-time babies

In this hospital endotracheal intubation is only used for the treatment of severe asphyxia The 9 infants who died without intubation were obviously severe, but for various reasons the treatment was not applied. In six cases an error of judgment was made in the initial assessment of the case which appeared to be borderline or moderate at birth; in others there was a failure of organisation or of technique The lesson we have learnt is that in cases of "borderline" severity it is better to intubate before it may be too late Table III shows details of all the infants who died, and the case histories which follow illustrate some of these points The latter are cases that occurred during the last twelve months of the survey, and were observed personally The table shows that all 3 infants who died in spite of intubation had extremely severe asphyxia and were intubated rather late In case 1 the initial response to intubation was poor The 2 other intubated babies died later from complications of asphyxia neonatorum When asphyxia has been prolonged or severe before birth, the outlook with any form of treatment is bad, but immediate endotracheal aspiration and oxygenation gives the best chance of survival

TABLE IV—PREMATURE BABIES INTUBATED

Birth weight (lb)	Survived	Died	Total
Less than 3	0	2	2
3–4	3	4	7
$4–5^1/_2$	15	3	18

Case 4—Birth weight 10 lb 10 oz Vertex presentation with shoulder arrest The baby was limp and apnoeic at birth, but the cord was pulsating After three minutes the baby was rocked in oxygen, but there was no respiration Intubation was not done until 10 minutes, but the infant was dead At necropsy there was complete atelectasis of the lungs

TABLE III—FATALITIES (FULL-TIME INFANTS)

Case no	Whether intubated	Age at intubation (min)	Comments	Clinical notes	Necropsy findings
1	Yes	10		Forceps, white asphyxia followed by gasping respiration died at 6 hours	Scattered areas of aeration lungs
2	Yes	10		Breech, white asphyxia respiration took 45 min to establish, convulsions after 24 hr, died at 3 days	Congested lungs and lungs floated
3	Yes	10		Cord round neck severe asphyxia, died at $15^1/_2$ hr	Scanty aeration inhalation pneumonia
4	No		Failure of organisation	Shoulder arrest, no spontaneous respiration, died at 10 min (see text)	Complete atelectasis
5	No			White asphyxia rapid onset of cyanosis at 24 hr died at 2 days	No necropsy
6	No		Borderline case	Forceps, cyanosed from birth, died at 48 hr	Atelectasis
7	No			Rapid delivery white asphyxia, died at $2^1/_2$ days	No necropsy
8	No			Rapid delivery, white asphyxia, died at 2 days	Bilateral aspiration pneumonia
9	No		Failure of organisation	Cyanosed since birth Improved on oxygen sudden collapse and death at 18 hr	Pneumothorax many subpleural bullæ
10	No			White asphyxia died at 20 hr	Atelectasis, ? hyaline m
11	No		Borderline case	Cæsarean section antepartum hæmorrhage, white asphyxia, improved spontaneously at first, but died at 24 hr	Bilateral atelectasis
12	No		Borderline case	See text	Bilateral atelectasis, membrane

---

* Since this was written we have been tremendously impressed by the value of *N* allyl normorphine hydrobromide (nalorphine hydrobromide) as an antidote to morphine given to the mother

TABLE V—COMPARISON OF RESULTS

Reference	Neonatal deaths per 1000 live births	Neonatal deaths due to asphyxia
ter and Adair (1943)	20·4	18%
istrar-General (1949)	19·3	17%
nty of London (1950)	16·9	21·6%
cher and Rogers (1951)	26·1	34·0%
pé and Pallin (1951)	13·8	—
mmersmith (1949–53) (present rks)	21·7	7%

several other full time infants, apparently equally oked at birth recovered after immediate intubation re most severely asphyxiated infant to survive was a ge premature infant

ase 13 —Birth weight 5 lb 6 oz Delivered by cæsarean tion at the 38th week for severe fœtal and maternal distress n accidental hæmorrhage Fœtal heart rate 70 before tion Liquor heavily bloodstained Infant gasped once a nute after delivery Thick blood aspirated from pharynx dotracheal intubation was done but tube became blocked h blood and was withdrawn 3 ml of blood aspirated from nach. Gastric oxygen given with no improvement dotracheal tube replaced at 5 minutes No improvement on tious intermittent pressures, baby gasping about once a nute. Given both continuous endotracheal and gastric gen for 2 hours Became pink at 15 minutes, and was thing regularly at 2 hours. Hæmorrhage into lungs and nach at 40 hours Given fresh blood transfusion Progress n uneventful Apparently normal at one month Sub ently did not attend follow up clinic

This case illustrates the benefit that may be derived a moribund asphyxiated infant when endotracheal gen is promptly administered Positive pressures e considered dangerous in this case owing to the norrhage In many other cases in which intermittent ufflation with oxygen was used the response has been re rapid and expansion of the chest wall was noted h each insufflation

The decision whether to intubate in a borderline e is a recurrent problem. No such infant who been intubated has died or has shown signs of pul nary or mental damage Case 12 illustrates this blem

ase 12 —Birth weight 6 lb 8 oz. Cæsarean section for ht antepartum hæmorrhage unaccompanied by fœtal ess. Pharyngeal suction not done on delivery Baby eared to have inhaled liquor but cried immediately ryngeal suction done at 2 minutes Baby then became ple and pale but as she gasped irregularly at 7 minutes was not intubated She breathed regularly at 10 minutes ough she was still pale Atelectasis persisted becoming e at 7 hours Intubation was done at 10 hours and gen given at positive pressure with no improvement mented respiration was then tried but after temporary rovement she died at 17 hours Necropsy showed hyaline nbrane

PREMATURE BABIES

Experience has taught us that endotracheal intubation not a satisfactory treatment for small premature ies, but in selected cases where the birth weight is r about 4 lb., it may be of value In our series there e 18 babies who survived this manœuvre Table IV es the number of those who were intubated

Small *premature babies*—Endotracheal insufflation oxygen is regarded as a satisfactory treatment of tial apnœa in larger babies Small premature infants ally attempt to breath shortly after birth unless it been necessary to give the mother large doses of atives or anæsthetic In our experience these few holic premature babies respond badly to tracheal heterisation One such case occurred in the last ar

Case 14 —Birth weight 3 lb 4 oz. Cæsarean section for ere pre-eclamptic toxæmia No spontaneous respiration so baby was intubated at 5 minutes. It immediately became severely shocked and died at 20 minutes in spite of augmented respiration

It was felt that the manipulation of catheterisation contributed to the death of this infant

LATE INTUBATION

Where atelectasis persists several hours after birth whether in full time or premature infants delayed intubation has been found to be an ineffective treatment. These infants are no longer flaccid, and the passage of a tube is more difficult and may cause shock Moreover in these cases any inhaled material will have reached the deeper part of the lung and aspiration of the main bronchi yields nothing The risk of trauma in these circumstances is increased.

SUMMARY OF IMPRESSIONS

Endotracheal suction and insufflation of oxygen form an effective treatment for the initial apnœa of full time infants and large premature infants We consider intubation in very severely asphyxiated infants to be life saving In moderate cases intubation is favoured if progress is unsatisfactory after 5 minutes In cases of borderline severity or suspected inhalation of amniotic material our experience has taught us to favour immediate intubation rather than to wait the routine 5 minutes This is especially important in babies delivered by cæsarean section who are most likely to develop hyaline membranes We have seen no case of hyaline membrane in full time babies that were normal at birth All have had clinical signs of atelectasis persisting and increasing from the moment of birth Until the cause of secondary atelectasis and hyaline membrane formation is better understood, it seems wise to aim at early oxygenation and the removal of inspired material from the trachea and the main bronchi

Results with Gastric Oxygen

We have no experience of giving gastric oxygen alone to mature infants because we have hesitated to deny them the benefits of endotracheal oxygen

Since June 1952 gastric oxygen has been the routine treatment for apnœa in premature infants, and every infant so treated has become pink We therefore rely on gastric oxygen to give some oxygenation of the blood stream and to enable the babies' respiratory centres to recover During this time postural drainage and pharyngeal suction are practised. If the baby cannot subsequently expand its lungs in spite of making respiratory efforts it is treated by augmented respiration

Improvement in Colour in Spite of Prolonged Apnœa

Case 15 —Birth weight 2 lb 8 oz at 30 weeks. Lived $3^1/_4$ hr on gastric oxygen and became pink without making a single spontaneous respiration Necropsy showed cerebral hæmorrhage

Satisfactory Respiration following Gastric Oxygen

Case 16 —Birth weight 2 lb 10 oz. at 32 weeks. Cæsarean section for severe hæmorrhage from placenta prævia. No spontaneous respiration Given gastric oxygen and intramuscular nikethamide Started to gasp 10 minutes after delivery Was still mildly cyanosed $2^1/_2$ hr after birth but subsequently did well

Case 17 —Birth weight 2 lb 10 oz. at 32 weeks. Induction for pre-eclamptic toxæmia (exchange resins) No response to oxygen and rocking for 10 minutes Gastric oxygen given at 10 minutes Baby responded to passage of tube—breathed. Gastric oxygen discontinued in 3 minutes

Respiration Established—continuing Rib Recession

Case 18 —Birth weight 1 lb. 9 oz at 28 weeks No spontaneous respirations in spite of pharyngeal suction and oxygen by face mask. Given gastric oxygen at 5 minutes Became pink at 10 minutes Breathed regularly but showed rib recession Gastric tube removed at 5 hours Sudden apnœa at 25 hours Died

Discussion

It can be calculated from the Registrar General's returns for 1949 that 17% of deaths in the first four weeks were attributed to asphyxia A similar calculation made from the annual report for 1950 for the county of London gives a figure of 21 6% Both these figures are probably too high, for it is notoriously difficult to diagnose the cause of death of newborn babies on clinical evidence alone Where a careful post mortem study has been made, however, it is still found that asphyxia causes a large proportion of the neonatal deaths For example, Potter and Adair (1943) found that 18% of 284 neonatal deaths were due to asphyxia

Some workers who have used endotracheal intubation have published figures illustrating their results

Fletcher and Rogers (1951) had 66 neonatal deaths in 2531 deliveries, 23 of these were due to asphyxia (9 per 1000)

Cappe and Pallin (1951), in 16,766 deliveries in which endotracheal suction, followed if necessary by insufflation, was the treatment for asphyxia, had a neonatal mortality of only 13 8 per 1000

Russ (1946), who intubated all of a consecutive series of 317 babies born by cæsarean section, achieved an 18 per 1000 mortality among babies delivered by this means compared with 87 per 1000 for a control group of 137 "cæsarean" babies

In contrast to the findings cited above and summarised in table v, a study of the published annual reports of several large maternity hospitals, where the standard of obstetrical care is comparable to our own and where most of the infants that die are examined post mortem, shows that at these hospitals asphyxia contributes only a small proportion of the total of neonatal deaths

Conclusions

The routine of this hospital for the immediate resuscitation for asphyxia neonatorum is early aspiration, endotracheal insufflation for mature infants, and gastric oxygen for small premature infants Persistent atelectasis is treated by augmented respiration We believe that endotracheal intubation is safe in skilled hands, and that this method, combined with the other procedures described, should reduce postnatal deaths from uncomplicated asphyxia to a minimum

We cannot claim that our methods are superior to others We reaffirm, however, that it is only by having a well planned and efficiently practised technique of resuscitation in the labour room that the number of deaths from this cause can be reduced Deaths from postnatal asphyxia are to a large extent preventable

We wish to thank Prof J McClure Browne for his coöperation, and Prof A A Moncrieff for his help and enthusiasm, which encouraged us to write this article

THE naturally occurring anticoagulant, heparin, i sulphuric ester of a complex polysaccharide The h of the chemical identification of heparin, and a re of its biological activity and therapeutic app have been presented by Jorpes (1946) Bergstrom (1936) and Chargaff et al (1936) showed that the sul esters of other polysaccharides have a similar but w anticoagulant activity This led to a search for s thetic substitute for heparin The toxicity of the sul esters of starch, glycogen, chitin, and various polysaccharides was investigated by Astrup and (1946), who found them to be active anticoagulant unsuitable for clinical use because in compar dosage they produced in laboratory animals a ten to bleeding

Sulphuric esters were prepared from dextran various molecular weights by Gronwall et al (1945) reported that the toxicity of their compounds de as the molecular weight decreased, but they did produce a satisfactory therapeutic compound Recent in Birmingham, investigations have been made in wh the differences in the molecular weight of the r dextran and of the sulphur content of the final have been related to toxicity and biological activ (Walton 1951, Ricketts 1952a, Ricketts and W 1952, Walton 1952, 1953a and b)

In experiments on animals it was found that molecules of dextran sulphate must be of an o size to reduce their toxicity to a level comparable that of heparin, and that a certain threshold of su content must be exceeded to ensure satisfactory a coagulant activity Molecules of dextran sulphate dimensions above the optimum size formed insol precipitates with the plasma proteins and especially f fibrinogen (Walton 1952) This was found to be asso with agglutination of the formed elements of the b (Walton 1953a) and with storage of the material reticulo endothelial cells and with other undesir pathological changes (Walton 1953b) On the o hand, molecules which were much smaller than optimum size were ineffective in vivo—pre cause of very rapid passage out of the blood-stream icketts 1952b and unpublished observations)

Dextran-sulphate molecules of optimum size and lphur content though less potent, weight for weight an commercial heparin appeared to behave in a quali tively similar biological fashion and to show com rably low toxicity (Walton 1953b) When the optimum olecular characteristics of dextran sulphate from the andpoint of its possible use as a substitute for heparin d been defined, a batch was prepared in the laboratory icketts 1952a) in an amount sufficient to allow thorough ological screening and subsequent therapeutic trial on limited scale at Birmingham

Pilot Clinical Trial

METHODS

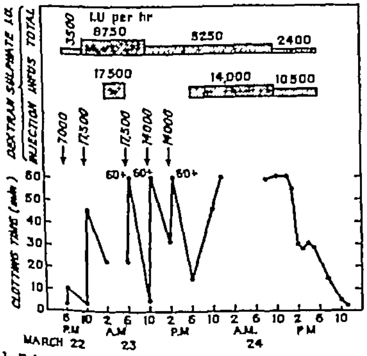
A 20% (*w/v*) solution of the material (batch I/3) in ysiological saline solution was sterilised by Seitz tration and tested to ensure sterility and freedom from rogens. The material was assayed against international ndard heparin by the method of Kuizenga et al (1943) d its potency expressed in heparin units. The solution ed contained 3000 units per ml

In the preliminary clinical trial at Birmingham no tempt was made to show clinical efficacy equal to or eater than that of heparin The limited objectives re (1) to show that dextran sulphate was an effective ticoagulant in man in vivo; (2) to establish, as far as ssible that its use was not attended by toxic effects her immediate or remote and (3) to obtain prelimi ry information about dose response relations. To fulfil e last of these aims dosage-levels were changed fre ently and the clotting time was measured two hourly the method of Dale and Laidlaw (1911–12) on pillary blood taken from the ear

The dextran-sulphate solution was administered intra nously either intermittently by repeated venepuncture se 1) or by continuous intravenous infusion in a solution 5% glucose in 0 45% saline solution (cases 1 2, and 3) uring therapy the following investigations were made total and differential estimation of plasma-proteins cluding fibrinogen) (2) full blood-count (including atelets) (3) erythrocyte sedimentation rate (E.S.R.) chemical and microscopical examination of the urine estimation of urinary excretion of dextran sulphate th toluidine-blue by the method of McIntosh (1941)

RESULTS

Case 1.—A man, aged 48, was knocked down by a falling ter On admission to the Birmingham Accident Hospital had flaccid paralysis of both legs, with anæsthesia below L1 Radiography showed a fracture-dislocation of the spine in the region T_{11} and T_{12} Open reduction was performed the same day Between the tenth and twelfth days a slight fever was noted and the right leg and thigh were seen to be swollen and discoloured The patient complained of a sudden pain in the right chest, which became worse with inspiration A diagnosis of venous thrombosis and pulmonary embolism was made



1—Dale and Laidlaw (1911–12) clotting-time response to dextran sulphate in case 1

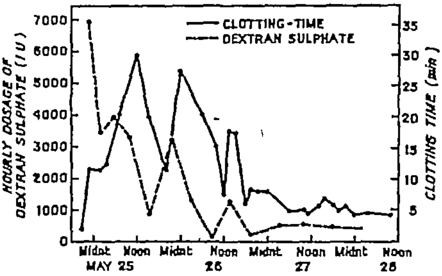


Fig 2—Dale and Laidlaw (1911–12) clotting-time response in case 2 to continuous infusion of dextran sulphate in saline solution by intravenous drip.

Anticoagulant therapy with dextran sulphate was initiated The dosage schedule of dextran sulphate and the clotting time response are shown in fig 1 After ten hours therapy the patient said that the pain in his chest had abated His temperature, pulse rate, and respiration rate were unaltered.

On the second day of treatment the method of administration was changed from intermittent injections to continuous infusion. The clotting time response altered from a succession of sharp peaks (the ' picket-fence ' curve of Duff et al 1951) to a smooth curve The clotting time could be kept reasonably steady at any desired level by appropriate adjustment of the drip-rate of the infusion

At the end of forty-eight hours the patient's colour and general condition were good, and no untoward effects had been produced by the dextran sulphate No alterations were observed in the levels of the platelets, white cells, and hæmoglobin or in the E.S.R. The plasma-protein levels were unaltered. Examination of the urine showed no abnormality Estimation of the dextran sulphate excreted in the urine (as material giving a metachromatic reaction with toluidine-blue) showed excretion of such material sporadically After forty eight hours the administration of dextran sulphate was discontinued. The clotting time was restored to its pre treatment level *in four and a half hours Anticoagulant therapy* was then resumed with heparin. The patient made an uneventful recovery and six months later was well and walking in callipers.

Case 2—A man aged 57 had had two previous attacks of thrombophlebitis involving first the left and then the right leg during the preceding year He was admitted to the Queen Elizabeth Hospital for investigation because of increasing dyspnœa and because a dense hilar shadow was seen when his chest was radiographed After five days in hospital he developed pain and swelling in his right leg with tenderness over the femoral vein in the groin and mid thigh A recurrence of thrombophlebitis was diagnosed.

Dextran sulphate was administered by continuous intravenous infusion for three and a half days The pain in the leg abated within eight hours, and the swelling had decreased by the third day of treatment The clotting time response is shown in fig 2. No untoward reaction was observed during the period of therapy and pathological investigations showed no deviation from the pre treatment values. During therapy the excretion of material giving a metachromatic reaction with toluidine-blue was noted in the urine

During dextran sulphate therapy the prothrombin time estimated by the one-stage method of Quick (1935) consistently showed a reduction to 30% or less. After three and a half days the treatment with dextran sulphate was discontinued. The clotting time was restored to normal in three and a half hours. Anticoagulant therapy was then resumed with Tromexan (3 3'-carboxymethylene bis-(4 hydroxycoumarin) ethyl ester) With physiotherapy and anticoagulants the condition in the right leg cleared to give a satisfactory result Six months later the patient was well and had had no further recurrence of thrombophlebitis

Case 3 —A man, aged 57, was knocked down by a motor-cycle, a week before admission On admission to Birmingham Accident Hospital no fracture was found on radiography, but there was gross swelling of the thigh, bruising of the right leg, and effusion into the right knee joint Six days later the swelling in the thigh was firm and indurated Tenderness extended along the saphenous vein as far as the pelvis A diagnosis of intramuscular hæmatoma with saphenous and femoral thrombosis was made It was considered that anticoagulant therapy might prevent extension of the latter, though the danger of possible renewal of bleeding from the torn veins in the thigh was recognised The patient's hæmoglobin was 60% of normal

Therapy with dextran sulphate was started by continuous infusion after three pints of blood had been transfused During the subsequent twenty four hours the patient's general condition improved He stated that the pain in his leg eased eight hours after the commencement of the infusion The tenderness over the femoral vein was less About thirty six hours after therapy began the patient complained of a sudden renewal of acute pain in the leg, with a feeling of tightness Bruising and discoloration of the skin on the lateral aspect of the leg (where none had previously been present) became apparent, suggesting renewal of bleeding from the site of injury The infusion of dextran sulphate was stopped Two pints of whole blood was transfused The clotting time was restored to normal in two hours, and there was no further swelling of the leg Ten days later the swelling appeared to be subsiding rapidly and the patient was up on crutches Thereafter, with the aid of massage and exercises, the patient's condition continued to improve Six months later the patient was well, with almost full movement of the limb

The results obtained in the first three cases were considered sufficiently encouraging to warrant further trial Material manufactured on a pilot commercial scale was supplied to three centres with considerable experience of anticoagulant therapy with heparin, for independent assessment

Extended Clinical Trials

MATERIAL

Two batches of dextran sulphate were prepared on a larger scale

These batches differed slightly in their method of production The first batch (no 5221) was produced by a method essentially similar to that used for the production of the material used in the preliminary clinical trial at Birmingham—i e, the material was made by sulphation of a dextran fraction considered to be of suitable molecular size Further experience of manufacture on this scale of production showed that this method did not ensure a constant uniformity of optimum dispersion of molecular size in successive batches A modification was therefore introduced into the method of preparation designed to ensure greater homogeneity of molecular size at the required level This modification consisted in fractionation of the final product, dextran sulphate, itself In the case of both batches the dextran sulphate, in the form of its sodium salt was dissolved in a buffered isotonic solution containing 0 72 % sodium chloride and 0 24 % sodium bicarbonate, sealed in ampoules, and sterilised by autoclaving The ampouled material was tested for sterility, pyrogenicity, and freedom from toxicity in vivo in a manner similar to that previously described (Walton 1953b) Both batches satisfied these requirements

The anticoagulant activity of the material was again assayed against a sample of international standard heparin The concentration of dextran sulphate was adjusted so that the final solution used contained either 900 or 1000 units per ml The characteristics of the two batches are as follows

Manufacturers' batch no	5221	52DSO39
Dextran sulphate (g per 100 ml)	5 7	8 15
Sulphur (g per 100 ml)	1 01	1 427
Intrinsic viscosity (dl per g)	0 03	0 03
Potency (heparin units per ml)	900	1000

It will be seen that, although both products showed the same intrinsic viscosity, indicating the same average molecular weight, they differed slightly in sul content and in activity

METHODS

In the extended clinical trials attention was ma directed to the following points

(1) The dose response relations were further investiga The technique of intermittent intravenous injections was almost exclusively since this is the method most used for heparin therapy

(2) Direct comparisons were made of the height duration of response to equipotent doses of heparin dextran sulphate in suitable cases

(3) A preliminary indication was looked for of the of individual variation of response to a given dose of sulphate

(4) Further confirmation of the lack of toxic effects sought

It is common clinical experience that, in cases thrombosis, heparin therapy is often attended by relief of pain and improvement in the general condition It has been suggested that this may be a vasodilator effect either generalised or localised to affected part Some preliminary observations were made, therefore, in selected cases, on changes in temperature after treatment with dextran sul Incidental observations were made to confirm the that dextran sulphate, like heparin, interfered with performance of the "prothrombin"-time test as w affecting the clotting-time Preliminary obser were made on the urinary excretion of dextran

CLINICAL TRIAL AT POSTGRADUATE MEDICAL SCHOOL LONDON

Batch 5221 containing 900 international units (I U) ml was used for this trial The work consisted in a istering (1) nine single intravenous injections of dosages to observe the effect on the clotting (2) repeated four-hourly intravenous injections (th the diaphragm of an indwelling Gordh needle) to patients to determine its efficiency as a thera agent, and (3) in one patient dextran sulphate compared with heparin on the same dosage

With Quick's modification (Quick et al 1949) of Lee and White (1913) technique, in which the clotting time is 5–10 minutes, adequate dosage regarded as that which prolonged the clotting about three times the normal when estimated an after injection

RESULTS

Single injections—Cases 4, 5, and 6 received venous i tions of 4500, 6750 I U dextran phate tively three occasions Clotting t were es ted before every h hour after each dose four hours response in three cases similar (fi All the clotting ti were normal After do

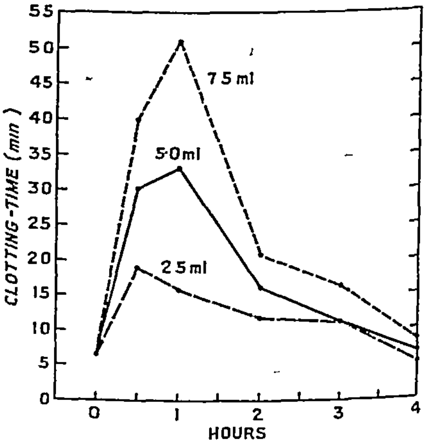

Fig 3—Lee and White (1913) clotting time response to single intravenous injections of dextran sulphate (1 ml = 900 I U) The curves show the means of the responses to different dosages in three normal people.

TABLE I—RESULTS OF CLINICAL TRIAL AT POSTGRADUATE MEDICAL SCHOOL OF LONDON

Diagnosis	Age (yr)	Initial clotting time (min.)	Drug and dosage (I U 4-hrly)	Clotting time (min.) after injection				Change in dosage (I.U 4 hrly)	Clotting time (min)			
				Day 1		Day 2			Day 3		Day 4	
				1 hr	4 hr	1 hr	4 hr		1 hr	4 hr	1 hr	4 hr
Popliteal thrombosis	75	9	Dextran sulphate 4500	20	13	51	17	None	60	19	92	25
Mitral valvulotomy venous thrombosis (calf)	35	6	Dextran sulphate 2700	12	8	14	8	Dextran sulphate 4500	15	10		
Myocardial infarction	70	8	Heparin 5000	27	8	32	7	Dextran sulphate 4500	32	18	72	18

0 4500 and 6750 I U of dextran sulphate, the longest tting times were recorded either half an hour or an r after injection, the mean figures being 17 28 and minutes respectively Four hours after injection the tting time in response to 2250 I U had returned to mal but was slightly prolonged in response to the her doses.

epeated injections—Treatment was given for periods to four days Case 4 received 4500 I U four hourly for r days, and case 5 received 2700 I U four hourly, reasing after two days to 4500 I.U four hourly for a ther day Case 6 received injections of 5000 I U of arin four hourly for two days After the clotting time l returned to normal 4500 I U of dextran sulphate given four hourly for a further two days In all three es the clotting times were estimated before therapy gan and subsequently twice daily, an hour and four rs after an injection The results are shown in table I se 4 receiving 4500 I.U four hourly showed a progres e increase in clotting time, the one hour clotting time ng 20 minutes on the first, and more than 90 minutes the fourth day of treatment. This additive effect ggested that at this dosage injections were being en too frequently—i.e. that at equipotent dosage duration of effect of dextran sulphate was greater n that of heparin This was borne out by the response case 5 in whom on a dosage of 2700 I U of dextran phate four hourly the clotting time was back to rmal after four hours but on a dosage of 4500 I U s still increased after four hours Direct comparison heparin and dextran sulphate in case 6 showed that ereas 5000 I.U of heparin four hourly produced mparable one-hour and four hour responses on con utive days, 4500 I U of dextran sulphate four hourly duced a progressive increase in the clotting time ponses at these intervals after injection

Side-effects—In case 4 receiving dextran sulphate 4500 I U four hourly a spontaneous bruise 4 cm in diameter appeared on the left forearm on the third day when the clotting time an hour after injection was 60 minutes. Apart from this no toxic or hæmorrhagic effects were seen

Investigations—Daily microscopy of the urine showed no red blood cells in any of the patients treated The E.S R. did not vary with changes in the clotting time Measurements of the skin temperature of the limbs after intravenous injection of dextran sulphate showed no significant rise of temperature

CLINICAL TRIAL AT GLASGOW ROYAL INFIRMARY

Batch 52DS039 containing 1000 I U per ml was used in this trial. Single intravenous injections were given to three volunteers and to a patient with coronary thrombosis (cases 7–10) Another volunteer (case 11) was given 5000 I U of the material intramuscularly a dose which was not considered to be of great practical value but was limited because of the relatively dilute solution available In cases 7 and 9 the effects of two similar intravenous doses given at intervals of seven to nine days were compared, and in case 10 the effects of equipotent doses of heparin and dextran sulphate were compared. The responses obtained are shown in table II It can be seen that after intravenous doses of 5000 I U the clotting time had not reverted quite to normal at the end of four hours (cases 8 and 10 (i)) The magnitude of the effect was greater with 10 000 I U intravenously (cases 7 and 9) but its duration was not obviously lengthened In case 10 the anticoagulant effect of dextran sulphate lasted longer than that of heparin The intramuscular injection of 5000 I U did not produce pain at the site of injection but produced only a slight lengthening of the clotting time. No toxic or hæmorrhagic effects were observed in the

TABLE II—RESULTS OF CLINICAL TRIAL AT GLASGOW ROYAL INFIRMARY

	Sex	Age (yr)	Diagnosis	Drug and dose (I U)	Route	Lee-White clotting time (min.)						Comment

cases in this series One patient died of extensive myocardial infarction on the day following the administration of dextran sulphate The case-history was as follows

Case 8—A woman, aged 52, was admitted to Glasgow Royal Infirmary with nine months' history of attacks of anginal pain relieved by rest and of increasing breathlessness on exertion A severe attack of "tearing" pain in the retrosternal region radiating towards the neck, with much weakness and nausea had come on nine days earlier and again on the day of admission. Coronary thrombosis with myocardial infarction was diagnosed Dextran sulphate 5000 I U was given intravenously at 2 35 P M and again at 12 45 A M on Jan 13, 1953 'Dindevan' (phenylindanedione) 150 mg was given at 12 45 A M. on Jan 13 Morphine sulphate gr $\frac{1}{4}$ was given at 12 25 P M, 4 50 P.M, and 10 45 P M on Jan 12 and at 1 20 P M on Jan 13 The patient became fairly comfortable after the initial administration of morphine and was pain free by 9 00 A M the following day By midday it was noted that the patient was becoming very shocked The pulse was very irregular, the systolic blood pressure was 80 mm Hg and the diastolic unobtainable In the heart, coupling and numerous extrasystoles were observed The patient became breathless, distressed, and restless, and died at 1 00 P.M

Post mortem the only significant findings were in the heart, the other thoracic and the abdominal organs being apparently normal The heart (420 g) was enlarged owing to dilatation of both ventricles An extensive area of recent infarction involved the lower half of the interventricular septum Nodular patches of atheroma were present in the coronary vessels, and the descending branch of the left coronary artery contained a thrombus adherent to the wall and filling the lumen from its origin for a distance of two inches

Microscopy of the liver, spleen, myocardium, adrenals, and kidneys showed no evidence of pathological change attributable to the dextran sulphate Sections stained toluidine blue showed no evidence of storage of giving a metachromatic reaction in reticulo-endothelial

CLINICAL TRIAL IN DEPARTMENT OF SURGERY, UNIV OF EDINBURGH

Batch 52DSO39 containing 1000 I U per ml was for this trial It was administered to seven (cases 12–18) by intermittent intravenous injections periods varying from two to seventeen days observations were also made in two other patients 19 and 20) Cases 16 and 17 were treated as being kept under observation for three or four hours each injection to allow the maximum effect of the to wear off

Results

The clinical results of therapy are shown in table from which it can be seen that they were good in cases of deep venous thrombosis and fairly good in case of multiple arterial emboli (mesenteric and fe Two patients with arteriosclerosis obliterans and of recent spread of thrombosis in one leg (cases 16 17) were treated with single intravenous in dextran sulphate 5000 I U for seventeen and days respectively Their claudication distances did alter during this time, but both patients spontane mentioned a subjective feeling of heat in one or feet, and in one patient (case 17) small ischæmic on the toes showed signs of healing by the tenth However, this patient, who had been treated as outpatient, died suddenly on the fourteenth day

TABLE IV—EFFECT OF DEXTRAN SULPHATE ON CLOTTING TIME AND ONE-STAGE "PROTHROMBIN" TIME

Case no	Age (yr)	Lee White clotting time (min.) at 37°C							Prothrombin time (Quick's one-stage) (sec.)						
		Before	Hours after dextran sulphate 5000 I.U I V						Control time	Hours after dextran sulphate 5000 I.U I V					
			$\frac{1}{2}$	1	2	3	5	7		$\frac{1}{2}$	1	2	3	5	
12	76	13	100 +			28	25	15	15 3	20 3			21 7	20 9	16
13	40	17*		90		47	22		17 4		20 2		20	19

19	64	14			90 +		26		15 3			22 7		20 7	

*Cases 13 and 14 showed unusually protracted responses to dextran sulphate The administration of 5000 I U twenty four hours was thought to be responsible for the high base line clotting times shown in either case enty hours after his last injection, with signs of ebral hæmorrhage. Necropsy was not performed and further details could be obtained from his doctor In lition to the signs of severe obliterative arterial disease the legs this patient had electrocardiographic changes licating myocardial ischæmia, and his blood pressure s 225/105 mm. Hg This patient was, in any case a sible candidate for a cerebral vascular accident and re was nothing to suggest that the incident took place en dextran sulphate was exerting an important icoagulant effect

Effects on clotting-time —The effects on the clotting e in seven patients and on the one stage prothrombin e (Quick 1935) in six patients for periods up to seven urs after the injection of dextran sulphate 5000 I.U shown in table IV It can be seen that although the ial response resembled that which might be expected m an equipotent dose of heparin the effect lasted ger A satisfactory clinical response was obtained in the cases treated with 5000 I U twice daily or in some es once daily Case 13 showed a much greater response n did the other patients to dextran sulphate his tting time was 21 minutes twelve hours after the injec- n of dextran sulphate 5000 I U on one day and on other day 17 5 minutes fifteen hours after a similar e. Case 14 showed a similar though less well marked ponse to the material These two cases are discussed ow

ther observations —Three patients remarked on a jective feeling of warmth which sometimes lasted o hours after an injection. Skin temperature record s were made in five patients Four of the five patients wed increases of 0 8°–5 5 C in skin temperatures, and effect was observed repeatedly in two patients The ximum effect did not occur until half to one hour r the injection The E.S.R did not vary significantly h changes in the clotting time but an occasional ease was noted.

EXCRETION OF DEXTRAN SULPHATE

aterial giving a metachromatic reaction with tolu e blue was found to be excreted in the urine during rapy with dextran sulphate in cases 1 and 2 This ervation was confirmed in cases 13 14 and 15 liminary quantitative studies showed that (1) hough the urinary level of this material decreased onentially after a single intravenous dose the total ount excreted appeared to vary with the volume of e secreted and to be increased by even a slight resis (2) considerable variation was found in the al daily excretion even in the same person on constant age on different days and (3) no correlation was onstrable between urinary excretion and sensitivity response of the clotting time For instance case 14 whom dextran sulphate produced an unusually tracted prolongation of the clotting time showed a ater daily excretion on the same dosage, than case 15 o showed a normal clotting time response This gested that increased sensitivity of response was not to failure to excrete dextran sulphate but possibly a slower rate of its inactivation in the blood-stream ther studies of this aspect are in progress In par lar, experiments with dextran sulphate of similar lecular composition but labelled with radioactive phur (S^{35}) are now being made to obtain a clearer ture of the metabolism and excretion of dextran phate

Discussion

From a consideration of the response in the twenty r people to whom dextran sulphate was administered ting the various clinical trials reported above it is ar that dextran sulphate serves as an effective anti ulant in clinical practice The clotting time response intravenous injection resembled that to equipotent doses of heparin in that intermittent dosage produced a picket fence curve and continuous infusion gave a smooth curve adjustable to any given level by appropriate adjustment of the rate of administration

The most noticeable difference was that of duration of effect Heparin 5000 I U administered intravenously prolongs the clotting time for 2 or 3 hours (Estes and Allen 1950 Duff et al 1951 Brown and Douglas 1952) The equivalent dosage of dextran sulphate produced an effect for five to seven hours. Thus when doses of dextran sulphate of this order were given by intermittent four hourly injections an additive response was obtained On the other hand, a constant clotting time response and satisfactory clinical results were obtained with a dosage of 5000 I U twice daily The intravenous administration of dextran sulphate produced an unusually prolonged effect in two patients (cases 13 and 14) This does not appear to have been due to failure to excrete the material effectively (see above) In these patients single daily injections were judged to be sufficient to secure the desired clinical effect Possibly these patients were hyper reactors ' to dextran sulphate Considerable differences in sensitivity of response to heparin have been reported in animals (Jaques and Ricker 1949) and in man (De Takats 1943 Duff et al 1951) De Takats reported that of 87 patients subjected to a heparin tolerance test 8 were found to be hyper reactors, 47 reacted normally and 32 were 'hypo reactors. The present series of patients treated with dextran sulphate is too small to yield similar information about the distribution of sensitivity of response to the synthetic analogue. From preliminary unpublished observations it seems likely that sensitivity of response to dextran sulphate may parallel that to heparin, but further information on this point also will have to await more extensive clinical experience

Since it is common practice to use heparin to cover the period of delayed effect encountered with the coumarin derivatives, it is of interest that dextran sulphate like heparin interfered with the 'prothrombin' time estimated by Quick's one-stage method This suggested the advisability, where dextran sulphate is used before coumarin therapy of taking a blood sample for the control "prothrombin' time before the administration of either type of drug

STANDARDISATION OF DEXTRAN SULPHATE

The material used in the present clinical trials was assayed and labelled in terms of heparin units This was an interim measure for the convenience of clinicians accustomed to heparin dosage in these terms and to facilitate the comparison of equipotent doses of the two anticoagulants. It was fully realised that comparison of potency on the basis of parity of in vitro activity might be regarded as unsatisfactory but it was felt to be necessary to provide a known and familiar yardstick for the preliminary work with dextran sulphate In view of the observed difference in duration of effect a sample of dextran sulphate has been submitted to the World Health Organisation Committee on International Biological Standards with a proposal that a provisional standard should be established for dextran sulphate itself

DOSAGE

From the evidence so far available it is concluded that dextran sulphate as at present standardised will produce a satisfactory clinical response in most cases when given intermittently at a dosage of 5000 I U six hourly or when given by continuous infusion at a dosage of 500–750 I U hourly

SIDE EFFECTS

In the cases so far treated no toxic side-effects have been observed Hæmorrhagic complications were noted in two cases a spontaneous bruise was observed in case 4, and recurrence of bleeding occurred in a recently traumatised limb in case 3 From the latter experience, it is apparent that dextran sulphate is no safer than any other anticoagulant for use where there has been recent bleeding On the other hand, cessation of dextran-sulphate therapy was followed by restoration of the clotting-time to normal in four or five hours, and this restoration was accelerated in emergency, as in case 3, by blood-transfusion In the present series no occasion arose for still more rapid counteraction of dextran sulphate, but it had been shown previously that the anticoagulant action of dextran sulphate, like that of heparin, is immediately neutralised by suitable amounts of protamine (Walton 1951)

Two patients died during the course of therapy In neither case was there any evidence that death was caused or accelerated by changes directly referable to the anticoagulant

The rate and magnitude of the skin temperature changes after intravenous injection of dextran sulphate were such as to make them of doubtful significance compared with the response usually obtained with drugs such as tolazoline hydrochloride ('Priscol'), which are thought to produce a vasodilator effect by direct blockage of the autonomic innervation to peripheral vessels and exert considerably quicker and more pronounced effects The slow and relatively feeble effect with dextran sulphate suggests that if there is any action at all it must be mediated by a more indirect mechanism It has been shown that intravascular blood clotting is accompanied by the release of a vasoconstrictor substance, sometimes described as "serotonin" (Janeway et al 1918, Hirose 1918, Zucker 1944, Rapport et al 1949), but that this substance is not released in heparinised blood Possibly the arrest of intravascular clotting, which may be presumed to take place during the treatment of thrombophlebitis with heparin or with dextran sulphate, may inhibit further production of such a vasoconstrictor substance and allow restoration of normal vascular tone Further experimental investigation of this aspect of these drugs is needed to support this hypothesis

Apart from its qualitatively similar activity to that of heparin as an anticoagulant, it has been reported that dextran sulphate also reproduces the behaviour of heparin in respect of other biological systems Its similarity of action in clearing the turbidity of lipid-laden plasma in vivo has been described by Brown (1952a b, and c) In addition it has been reported to inhibit the action of complement (Lambert and Richley 1952), to prevent the heat-coagulation of albumin (Hamer 1953), to act as an anti-hyaluronidase in high concentrations (C R Ricketts and M Hall, personal communication), and to prevent the release of histamine like substances from rabbit plasma in vitro (Haining 1953) The use of dextran sulphate as an anticoagulant for the collection of blood samples from cardiac catheters and indwelling arterial needles has been described by Wade, Bishop, Cummings, and Donald (1953) Other in vitro uses have been reported by Hall and Ricketts (1952)

COMPARISON OF DEXTRAN SULPHATE WITH EXISTING ANTICOAGULANTS

Until recently the choice of drugs for anticoagulant therapy has lain between heparin and one or other of the coumarin derivatives Heparin, though in many ways an ideal anticoagulant in allowing considerable latitude of dosage with safety, has certain disadvantages (1) it necessitates frequent parenteral administration, and (2) since it is derived from animal tissues, it is difficult and expensive to extract and purify, it gives rise occasionally to sensitisation reactions, probably from the presence of protein impurities, and when derived from different sources it seems to vary in chemical composition a physical characteristics (Jorpes and Gardell 1948)

Recently the therapeutic trials of three "heparin" preparations have been reported 'Paritol' (a sulp ester of polymannuronic acid) though an effective a coagulant, produced some undesirable reactions, the severe being a generalised vasomotor collapse (Seifter a Begany 1948, Sorenson et al 1949, Sorenson and Wr 1950) 'Thrombocid' and 'Treburon,' sulphuric e of other polysaccharides, have been reported to prod severe diarrhœa and late alopecia (May 1951, Field et 1953) During the present investigation of dext sulphate no similar toxic effects have been observed.

It appears from our present results that de sulphate resembles heparin in being comparably safe non toxic, in being quick-acting, in losing its e rapidly on withdrawal, and in its capacity for neutra tion in emergency It must also be administered pa terally, but its somewhat greater duration of antico lant effect allows its administration at longer inter The control of therapy requires no more elab investigation than estimation of the clotting time be each injection The relative ease of its manufac should allow cheaper production Since it is synthe from purified protein free material (dextran) it is unlikely to give rise to protein sensitisation react and it can be produced to specified chemical and p cal characteristics Its qualitatively similar effect biological systems, other than the clotting mechan which are influenced by heparin makes it a useful exp mental tool for the investigation of these phenom

Summary

Clinical experience of twenty cases in which dext sulphate was administered in various dosages and various periods, from a single injection to contin therapy for seventeen days, suggests that dextr phate is an effective anticoagulant producing a re qualitatively resembling that of heparin but la somewhat longer No serious side effects have observed

We wish to express our indebtedness to Prof J R S and Dr J P Bull for their interest and helpful crit during all stages of this investigation, to the Medical R Council Blood Transfusion Committee for help in the co of these trials, to Prof Melville Arnott and Mr J Clarke for their coöperation in allowing us access to the for the preliminary clinical trial at Birmingham, to Sir Learmonth, Dr J F Goodwin, and Prof L J Davis fo supervision of, and interest in, the cases treated in Edin London, and Glasgow respectively, and to Prof. G Montgomery for permission to summarise the necropsy on case 8 and for access to the blocks and sections of necropsy material In particular, our thanks are d Messrs. Dextran for the gift of dextran sulphate prepared to our specification for the extended clinical and to their technical staff for enthusiastic coöperation meeting our requirements. The dextran sulphate used in trials described above is the subject of Patent Ap no 695,787 and other applications which have been a to the National Research Development Corporation, 1, T Street, London, W 1

One barrier to further advances in cardiac and cerebral urgery is the difficulty of maintaining an adequate w of oxygenated blood to the vital organs during mplex surgical operations Hypothermia by reducing e body temperature and consequently the body etabolism is one method of attaining this end It has en used on a limited scale in medicine and surgery for any years; in the Napoleonic era local cooling of the sues was successfully used for amputations during the treat from Moscow More recently, general body cooling s been suggested as a method of treatment of cancer mith and Fay 1940) and for use in surgery in man igelow et al. 1950 Juvenelle et al 1952a Delorme 52 Cookson et al 1952)

The method most widely adopted for reducing the dy temperature is cooling the environment of the æsthetised patient. Delorme (1952) has suggested that oling the blood by an artificial arteriovenous anasto- osis may have certain advantages. The creation of an teriovenous fistula alone, however causes profound ysiological changes (Holman 1937) and entails an lditional operation with its concomitant risks. We have ed this method as well as cooling of the pleural and peritoneal cavities with either cold water or a cooling coil. In each case the body temperature was reduced satisfactorily but of all the methods studied surface cooling appeared to be the simplest and safest technique and for this reason an investigation was undertaken to reassess the possible dangers before its application to surgery in man

Method

30 unselected mongrel dogs weighing 8–15 kg were used. Each dog was premedicated with promethazine hydrochloride ('Phenergan') 5 mg per kg of body weight subcutaneously Anæsthesia was induced with intravenous thiopentone sodium 0·015 g per kg of body weight followed immediately by succinylcholine chloride 5 µg per kg of body weight. The trachea was intubated, a cuffed tube being used, and anæsthesia was maintained with oxygen and ether in a closed-circuit apparatus with carbon dioxide absorption

When the dog had been anæsthetised control readings of body temperature, pulse rate blood pressure, electrocardiogram and oxygen consumption were taken The dog (unshaven) was next immersed in a bath of water at about 18–20 C After a few minutes crushed ice was added so that the temperature of the water rapidly fell to 2–6°C 20 dogs (series I) were cooled in this manner until their rectal temperature had fallen to 24°C when they were stabilised at 22–24°C for at least thirty minutes before being rewarmed. 10 dogs (series II) were cooled in an identical manner to 28–26°C for a similar period and then rewarmed. In both series the body temperature continued to fall a further two or three degrees after removal of the iced water from the bath

Rewarming was done by raising the temperature of the water in the bath to 42°C With the onset of shivering and returning consciousness the dog was removed from the bath dried, and placed in a warm recovery room

The body temperature was measured with thermocouples, one placed high up in the rectum or in the sigmoid colon and another inserted through the jugular vein into the right auricle In later experiments the rectal temperature alone was recorded, because the difference between the two readings was never more than ±1°C. All the readings were periodically checked against a standardised centigrade thermometer throughout each study

Blood pressure was measured with a mercury manometer connected to a cannula in the right femoral artery

The electrocardiogram lead II was continuously displayed on an oscilloscope throughout each study

Oxygen consumption was determined with a Benedict-Roth spirometer filled with the anæsthetic mixture of oxygen and ether

Defibrillation, when used, was preceded by cardiac massage and the intracardiac injection of 0 5 ml 1 : 1000 adrenaline sulphate when the fibrillation was not vigorous. The voltage used was 150–300V with a duration of 0 2 millisec. (McMillan et al 1952)

Results

SERIES I

The mean values of the body temperature blood pressure pulse rate, respiratory rate and oxygen consumption of 20 dogs cooled to 24–22°C are shown plotted against time in the accompanying figure

Blood-pressure showed a slight initial rise at the start of cooling but then fell gradually with the body temperature to about 29–26°C when the fall in blood pressure became more rapid in relation to the body temperature The average mean blood pressure in the anæsthetised dog at normal body temperature was 110 mm Hg falling to 48 mm Hg at 22°C—a reduction of 56%

Pulse rate fell gradually in unison with the body temperature The mean control value at normal body

Mean results of cooling twenty dogs to 24–22°C

temperature was 192 per min , falling to 58 per min at 22°C—a reduction of 70%

Respiratory rate increased when the dog was first immersed but afterwards gradually diminished as the body-temperature fell, finally ceasing at various temperatures depending largely on the depth of anæsthesia 7 dogs (35%) were still breathing at 23–21°C when rewarming was started, whereas 6 (30%) stopped breathing at 27–26°C, and the remainder (35%) at 24–19°C The mean respiratory rate of the anæsthetised dogs at normal -body-temperature was 56 per min , falling to 8 per min at 22°C—a reduction of 86%

Oxygen consumption was progressively reduced as the body-temperature fell The extent of the fall above 28°C depended largely on the depth of anæsthesia , below this temperature a strikingly uniform reduction was noted The mean control value at 38°C was 12 6 c cm per kg of body-weight per min , falling to 5 2 c cm per kg body-weight per min at 28°C, and to 2 0 c cm per kg of body-weight per min at 22°C—a reduction of 84%

Shivering was observed in 3 dogs during cooling It was abolished by increasing the depth of anæsthesia in each case

Cardiac arrhythmias were observed in 14 dogs (70%) at 24°C or less, whereas the remainder (30%) maintained a normal rhythm at 22–19°C The electrocardiographic changes most often observed were prolongation of the P–R interval and Q R S complex, flattening and deep inversion of the T waves, and depression of the S–T segment

Rate of Cooling —The average time taken to reach 24°C from normal body-temperature was 70 minutes

Mortality and Morbidity —There were 5 deaths in this series, the other dogs showing no ill effects from the cooling

Dog no	*Cause of death*	*Body-temp (°C)*	*Time of death*
1	Pulmonary collapse	38 2	48 hr after study
2	Ventricular fibrillation	22 5	93 min. from start of cooling
3	Ventricular fibrillation	22 0	80 min
4	Ventricular fibrillation	22 0	140 min
5	Pulmonary œdema	38 0	8 hr after study

Each case of spontaneous ventricular fibrillation was preceded by a variable period of cardiac arrhythmias All [illegible]mpts at resuscitation failed

Dog 1 made an apparently uneventful recovery V it was eating well in the morning, but it became progr more drowsy as the day advanced and finally died fort hours after the study Necropsy showed gross collap both lungs, only the right lower lobe and part of the left lobe being aerated

Dog 5 made an uneventful return to normal tempera Six hours after the study it was walking around and wag its tail Two hours later, however, it was found de Necropsy showed severe pulmonary œdema

All these 5 deaths took place in adult dogs 4 pupp which were unaffected by this study were subsequent cooled to body-temperatures of 16°, 14°, 11°, and 10 without developing ventricular fibrillation

SERIES II

10 dogs were cooled to 28–26°C for at least th minutes and then rewarmed None of them died, a no cardiac irregularities were observed in this series, the dogs making a complete and uneventful recov The changes in pulse rate, blood pressure, and respira were similar in every respect, except degree, to th recorded in series I The average mean control val for the blood pressure at 38°C was 131 mm Hg, fall to 95 mm Hg at 28°C—a reduction of 27% The mea control value for the pulse rate at 38°C was 197 per m falling to 110 per min at 28°C—a reduction of 44% Th respiratory rate was the same at 38°C and 28°C, thou there was an initial rise at the start of cooling Th average time taken to reach 28°C was 44 min.

Discussion

This study represents a control series designed to sh some of the physiological changes that take place dur the reduction of body temperature by surface coo without any surgical intervention The results indic that surface cooling offers a simple and safe method reducing the body-temperature, provided the rec temperature does not fall below 26°C Below th temperatures cardiac arrhythmias become the rule a more rarely, proceed to ventricular fibrillation. from this, a lower body-temperature in dogs is f by an incidence of pulmonary complications which easily explicable

The method of premedication and anæsthesia us this study was chosen because it was most closely to that used in clinical surgery in man For this re the use of drugs was strictly limited The advantag the anti histamine drugs over the more conventi methods of premedication was not shown, but the of large doses of barbiturates and other respirat depressant drugs is contra indicated because the red metabolism leads to a more prolonged action, and th fore a delayed recovery, as had been shown in prev studies

Inhalational anæsthesia has the advantage th depth of anæsthesia can be controlled to abolish shi and yet allow the rapid return of consciousne rewarming It is believed that shivering during co may have serious consequences in patients with ca disease The use of the muscle relaxants obviates risk of shivering and at the same time allows a l level of anæsthesia, and it has been found that neo mine was an effective antidote to a competitive inhib block at 28°C in both man (1 case) and animals.

The use of carbon dioxide absorption under condit of hypothermia may be criticised on the grounds washing out carbon dioxide increases the effect of low temperature in shifting the oxygen dissociation c of blood to the left, thereby hindering the liberation oxygen to the tissues (Brown and Hill 1922, Pe 1951) It is unlikely that there was an excessive wash of carbon dioxide in these dogs, since assisted respir was not given, but this effect may be important in under controlled respiration

The absence of respiratory activity in some dogs at ·C and below depended largely on the depth of anæs esia but in all the cases respiration had ceased at °C At 30–28°C the dogs required only light anæs esia to prevent shivering and at about the same mperature the value for oxygen consumption became markably consistent from dog to dog On rewarming ontaneous respiration began again at 24–28°C

There is no doubt that the chief barrier to profound ypothermia is the risk of spontaneous ventricular brillation The cause of this at these low temperatures emains unknown, and some method of preventing it ust be found before cardiotomy can be done with afety under hypothermia Anoxic anoxia cannot be a ontributory cause, for full arterial oxygen saturation is aintained—indeed an additional amount of oxygen is ssolved in the plasma Also it has been shown that oronary-sinus blood is normally desaturated, suggesting at the heart muscle can still take up oxygen However ing et al (1949) point out that heart muscle under sual conditions at normal temperatures extracts con derably more oxygen from the blood than do other ssues, and they show that increased demand is met by increased perfusion rather than further arterial aturation. In this context may be cited the experi ents of Lange et al (1949) who subjected hypothermic bbits to an oxygen pressure of five atmospheres and so doing restored the electrocardiogram to normal milarly acidification of the blood temporarily led to e same result. The combination of hypotension low rdiac output, and decreased dissociation of oxygen ay well account for sufficient cardiac anoxia to induce rhythmias. A further suggestion which might explain e increased "irritability" is that it is due to a direct fect of cold on the pacemaker and conducting tissue uvenelle et al 1952b)

The finding that ventricular fibrillation at 22 C and low was irreversible must be emphasised Other orkers' experience, however confirms our own finding at it is reversible at higher temperatures (B A Cookson d D Ross, personal communications)

It may come to be regarded as axiomatic that the unger the dog the better it withstands the cold. In is respect the experience of Adolph (1951) has been nply confirmed in our series, and there is good reason believe that it has been confirmed in man (S Kaplan d B A. Cookson, personal communications) The idence of ventricular fibrillation may confine the plication of deep hypothermia to a very limited age oup and mild hypothermia in combination with a chanical oxygenator (Melrose 1953) may become the hnique of choice in older children and in adults

Conclusions

From this investigation certain tentative conclusions ay be drawn for the use of hypothermia in surgery

(1) The particular method used to lower body tem rature is not of great importance but of the various ans available surface cooling is the simplest

(2) Until some method is found of preventing ven cular fibrillation the body temperature should not reduced below 26°C, and in all cases in which hypo rmia is used continuous electrocardiograms should displayed

(3) Hypothermia may offer an advance in surgery for erations requiring temporary occlusion of the great sels, but the increased irritability of the cardiac scle at temperatures of 25 C and below is the chief k of operations on the heart under these conditions

(4) The age of the animal is of particular importance the younger the animal the greater the margin of fety

This work was done at the Buckston Browne Research rm by kind permission of the President and Council of the Royal College of Surgeons Part of the equipment was provided by a grant from the St. Thomas's Hospital Endowment Fund We would like to thank Miss J F Davenport for invaluable secretarial assistance

NECROTISING ENTERITIS FOLLOWING GASTRIC SURGERY

M R Williams
B.M. Oxfd, F R.C.S
SENIOR REGISTRAR

J M Pullan
M.A., M.Chir Camb., F.R.C.S
SURGEON

ST THOMAS'S HOSPITAL, LONDON

During the last five years 10 cases of severe diarrhœa, associated with circulatory collapse occurring two or three days after operations on the stomach, have been observed in this hospital Of these 10 patients 5 have died, and in each case necropsy has shown necrosis of the mucosa of the small bowel. The clinical course of the 5 survivors was so similar that it seems reasonable to treat them as a homogeneous group and to assume that the pathology is the same.

Such a condition is not new, and 2 cases of Riedel's (1902) one following a high subtotal gastrectomy for carcinoma, and the other a Billroth I for benign stricture seem to be typical.

The subject has been reviewed by Penner and Bernheim (1939) and Penner and Druckerman (1948) who give an admirable historical survey Further cases following various operations are reported by Dixon and Weismann (1948) from the Mayo Clinic But we have been unable to trace any recent records in the English literature.

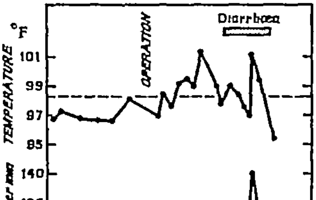

Fig 1—Chart of case 1 showing reactions to pulmonary atelectasis on second day and to necrotising enteritis on third day after operation

Case records

Case 1 —A Billroth I type of partial gastrectomy was performed on a fit man, aged 51 for a long-standing gastric ulcer No particular difficulties were encountered at the operation, and his immediate postoperative condition was satisfactory Next day, however, he had the signs of pulmonary collapse at the left base associated with a rising temperature, pulse rate, and respiration rate (fig 1) This responded to routine treatment, and on the morning of the third postoperative day his temperature had returned to normal and the signs in his chest cleared Gastric aspiration and the administration of rectal fluid were stopped By then, however, he was complaining of epigastric colic His abdomen was distended, but bowel sounds were present That evening his temperature, pulse rate, and respiration rate rose sharply, and he passed five very offensive loose motions Early next morning (fourth postoperative day) his condition was desperate he was cyanosed and dyspnœic, and his blood pressure was unrecordable He died at 11 P.M., eighty four hours after the operation, having had profuse diarrhœa during the day He was considered to be a case of bilateral pulmonary collapse, and his rate of decline was so rapid that no explanation of the abdominal symptoms was reached and no intravenous fluids were given

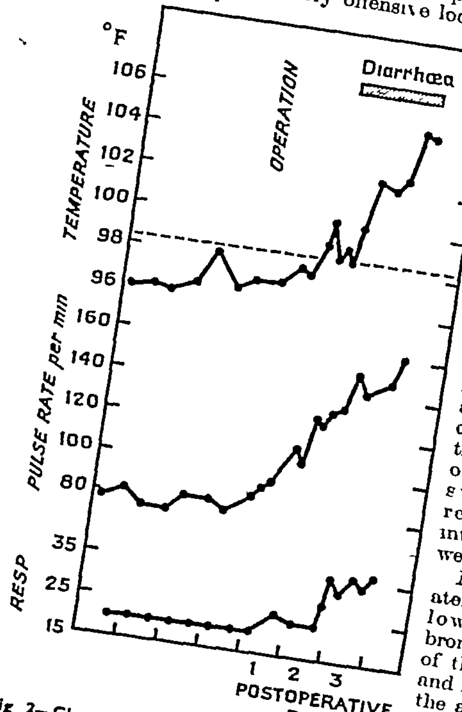

Fig 2—Chart of case 3 showing reactions on evening of first postoperative day to necrotising enteritis

Necropsy showed atelectasis of both lower lobes with bronchopneumonia of the right upper and lower lobes In the abdomen there was no peritonitis and the anastomosis was intact but in the upper half of the small intestine the mucous membrane had sloughed leaving only a few adherent white shreds

This may be regarded as a typical case of the condition under discussion The points to be noted are

A gastric operation is performed on a fit person and followed by an uneventful immediate postoperative course of about two days (though in case 1 it was complicated by a transient pulmonary collapse) On about the third day the patient complains of colicky epigastric pain, accompanied by abdominal distension, with normal bowel sounds He develops severe offensive diarrhœa, becomes dehydrated, and passes into circulatory failure, associated with fever, tachycardia and cyanosis In the absence of suitable treatment death is rapid Necropsy shows very little apart from the sloughing of the mucosa from various parts of the small intestine There is no peritonitis

The main points of the 9 other cases are as follows

Case 2—A partial gastrectomy was done in a patient, aged 38, who had unsuccessfully undergone vagotomy and gastro-enterostomy previously The operation was difficult and long, and the patient was shocked on returning to the ward but responded to blood transfusion His condition was satisfactory until the evening of the second day when he complained of colicky epig[illegible] pain His abdomen was distended, and bowel sounds were present He vomited once and developed offensive diarrhœa, which continued for twelve days, 50–100 oz. of fluid being passed a day Fluids, including plasma, were replaced intravenously throughout this time, and he made a good recovery and suffered no late ill effects, apart from homologous serum jaundice three months later

Case 3—Vagotomy and gastroenterostomy was performed on a fit man, aged 47, for duodenal ulcer, without difficulty His condition was satisfactory until the evening of the first day, when his temperature, pulse rate, and respiration rate rose (fig 2) Next morning he deve diarrhœa, and by the second evening his blood pressure dropped to 80/50 mm Hg An intravenous infusi saline was started but he remained in "circulatory colla and died within six hours, three and a half days operation

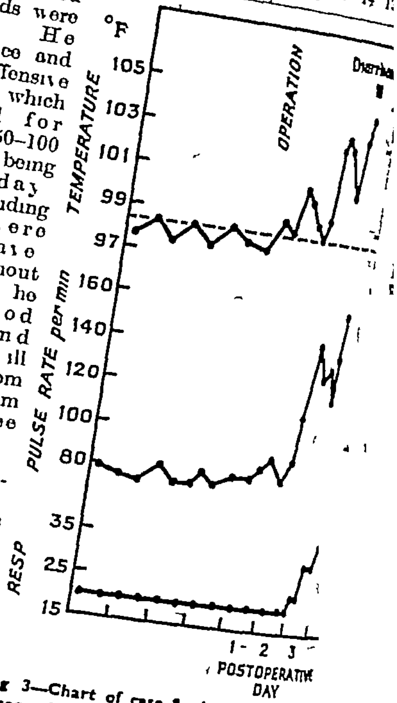

Fig 3—Chart of case 8 showing reaction second postoperative day to enteritis

Necropsy showed sloughing of the mucosa from the intestine from 30 cm below the anastomosis to 50 cm. the ileocæcal valve There were no other findings of no

Case 4—A fit man, aged 44, developed offensive dia with a rising pulse rate on the third day following a Bil type of partial gastrectomy for gastric ulcer, which pre no particular difficulties He was treated energetically intravenous fluids and made an uneventful recovery diarrhœa had ceased on the sixth postoperative day

Case 5—A Polya type of partial gastrectomy was perf with some difficulty on a fit man, aged 30, for duodenal His immediate postoperative course was uneventful, the evening of the third day he developed colicky ep pain with abdominal distension and a pulse rate of 1 temperature of 101°F Bowel sounds of normal quality present Next morning he developed profuse offensive rhœa and throughout the day he continued to be in circulatory collapse until the evening, when he died, 10 after operation 2 litres only of saline solution was intravenously during the last nine hours *Necropsy*

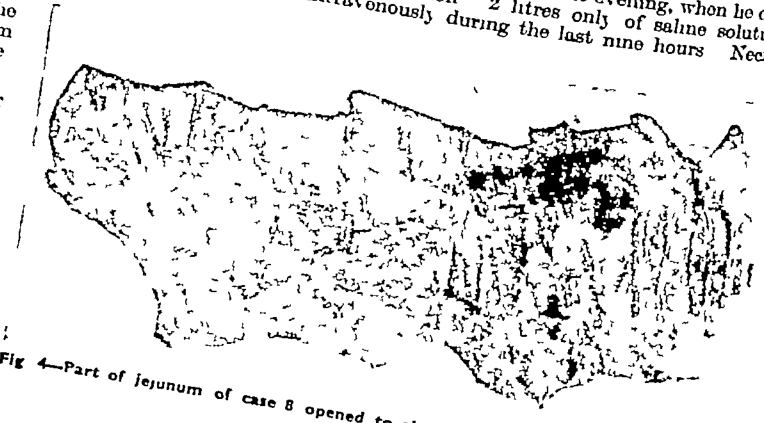

Fig 4—Part of jejunum of case 8 opened to show necrotic mucosa separating as a slough denuding the submucosa.

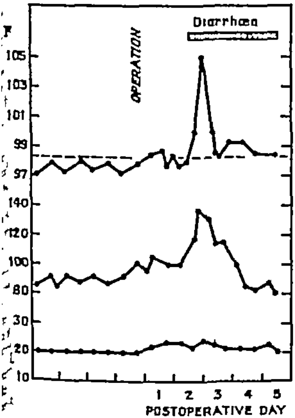
peritonitis and the suture lines were intact. The jejunum d ileum were distended with fluid The mucosa of the um was necrotic and had formed a tubular cast The ange in the mucosa of the jejunum was more patchy and ged strips of mucosa were loosely adherent to the bowel ll The colon was normal

Case 6 —A fit man aged 43 underwent an antecolic Polya pe of partial gastrectomy for chronic gastric ulcer His mediate condition was satisfactory but on the evening of third day he developed diarrhœa with a temperature of °F The diarrhœa continued five times daily for two days s fluid balance was maintained with intravenous saline ution and glucose He made an uneventful recovery

Case 7 —A Bilroth I type of partial gastrectomy was done an emphysematous but otherwise fit man, aged 65 for nign gastric ulcer On the evening of the first postoperative y he was distended and complained of epigastric colic On second day he was very ill and dehydrated his abdomen s distended but the bowel sounds were present and normal ur offensive fluid motions were passed Preliminary intra nous therapy was started, but was discontinued, after only 0 ml had been given owing to sacral œdema On the third y only 180 ml. of urine was passed in the twenty four hours, d the blood urea level was 173 mg per 100 ml (preoperative el 25 mg per 100 ml) On the fourth day the general dition improved after the administration of 4 litres of 3% line solution intravenously but next day auricular fibrillation developed and the patient died in a state of circulatory collapse on the evening of the sixth day

Necropsy showed that from a short distance below the duodenum the mucosa of the entire small bowel was congested and in places desquamated to form a cast There were also several discrete hæmorrhagic ulcers. These changes extended to the ileocæcal valve and increased in intensity distally The whole small intestine was distended with gas and large quantities rown fluid. The large bowel showed similar though much intense change. There were no other findings of note



5—Chart of case 9 showing reactions to crotising enteritis on second postoperative day d rapid improvement on rehydration on rning of third day

ase 8.—An anterior Polya type of partial gastrectomy done on a fit man aged 54 without incident. Apart from inent pulmonary atelectasis his condition was satisfactory il the evening of the second day when he complained of ere colicky epigastric pain associated with abdominal ension and active bowel sounds. His chart was typical 3). By next morning he was in severe circulatory collapse a diagnosis of internal hæmorrhage was made 2 pints h of dextran and blood were rapidly infused without evident efit. Only then did the passage of one offensive fluid motion l to a correct but belated diagnosis, and 4 litres of avenous glucose or of saline solution was administered. patient rallied for a little, but died eighty four hours after operation.

t *necropsy* the suture lines were healthy and there was no tonitis. The stomach, duodenum, and upper small bowel greatly distended with fluid From 1 in. below the stomosis and for the next 4 ft the jejunal mucosa was rotic and in most places separated as a yellow opaque gh (fig 4) In places this was adherent but the greater part lay free as a bolus in the lumen some 8 ft from the anastomosis The denuded surface was red raw and granular The large intestine contained at least 2 litres of watery brown fluid There were no other changes of note

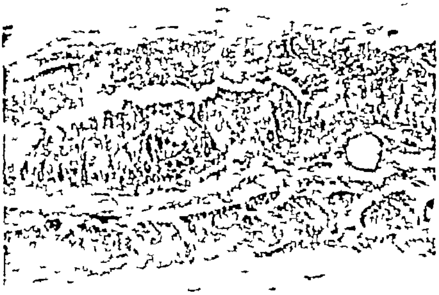


Fig 6—Section of small bowel showing necrosis of superficial glands of mucosa, with separation starting and survival of some glands in deeper parts. (Hæmatoxylin and eosin. × 33.)

Case 9 —A palliative partial gastrectomy for carcinoma of the stomach was performed without difficulty on a woman aged 53 Her condition was satisfactory until the afternoon of the second day when she developed colicky abdominal pain with sweating and very profuse offensive diarrhœa, passing 5 litres in two hours. She quickly passed into circulatory collapse and her temperature chart is shown in fig 5 Her diarrhœa continued to be very profuse Necrotising enteritis was diagnosed and intravenous glucose and saline solution were given as quickly as possible 10 litres was given in three hours and after this her condition rapidly improved and her temperature dropped dramatically A total of 16¹/₂ litres of saline solution and 2 pints of blood were administered in twenty four hours The diarrhœa decreased for eight days, and hydration was maintained by intravenous fluids The patient made an uneventful recovery and showed no late effects of the small bowel lesion

Case 10 —A rather wasted man aged 61 underwent operation for what was clinically thought to be a carcinoma of the stomach but proved to be a benign gastric ulcer A Polya type of partial gastrectomy was done without difficulty His condition caused no anxiety until the third day when he

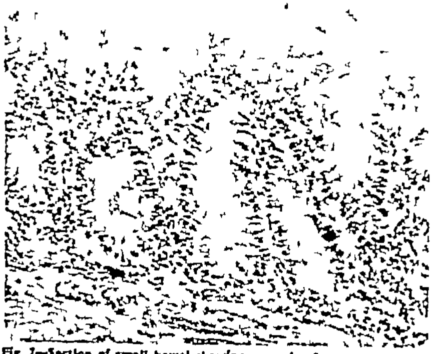

Fig 7—Section of small bowel showing necrosis of mucosa but little change in submucosa. (Hæmatoxylin and eosin. × 112.)

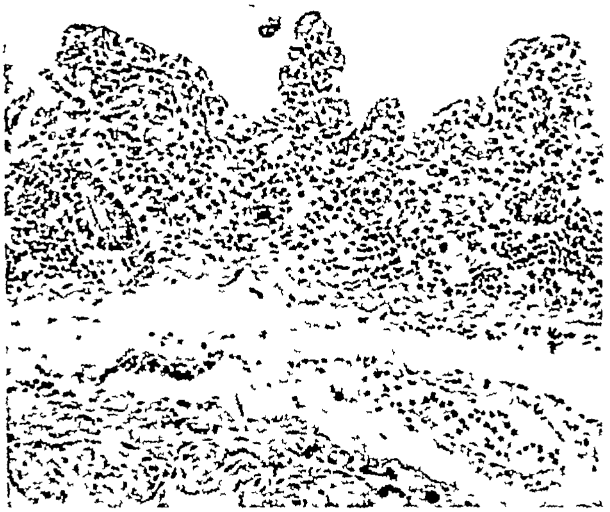

Fig 8—Section of small bowel showing necrosis of superficial layers of mucosa, with survival of isolated glands (Hæmatoxylin and eosin × 112.)

developed epigastric colic and a distended abdomen with active bowel sounds He also passed five offensive loose stools $2^1/_2$ litres of saline solution and 1 pint of plasma were given during the next twenty four hours This proved inadequate, and by the afternoon of the fifth day the patient was cold, cyanosed, and in circulatory collapse 4 litres of intravenous saline solution was then given in five hours, and his condition rapidly improved A further $5^1/_2$ litres of saline solution and glucose was run in during the next twenty four hours. He made an uneventful recovery, the diarrhœa finally settling on the ninth day

Discussion

The clinical picture of a patient who, on the second or third day after a gastric operation, develops colicky epigastric pain, abdominal distension with active bowel sounds, and raised temperature, pulse-rate, and respiration rate, and proceeds to profuse offensive diarrhœa and severe vascular collapse is unmistakable when presented in a series like this In many ways the condition is analogous to cholera and requires similar restorative therapy Some of these cases have been mistaken for pulmonary atelectasis, leak at the anastomosis, paralytic ileus, or internal hæmorrhage If, however, the condition is recognised and adequate fluid is promptly replaced intravenously, the patient immediately improves This may involve the rapid infusion of very large quantities of fluid In the last 3 cases intravenous aureomycin has also been given, for reasons discussed below, but this is of doubtful value In patients who recover, the diarrhœa stops after about a week, and in none of the surviving patients had there been any late complications In 2 of them the small bowel pattern shown by barium was normal before discharge from hospital

PATHOLOGY

The pathology of the fatal cases is equally consistent In all 5 of them the necropsy findings, apart from the lesions in the small intestine, were insignificant There was no peritonitis, and the anastomoses appeared healthy The external appearance of the small bowel was unremarkable, and there was no obvious enlargement of the mesenteric glands In every case, however, when the small bowel was opened, it was found that the mucosa had sloughed to form a membrane, which had either completely separated and passed down the gut or was still partly attached to the remaining bowel wall This necrosis is often patchy and more severe in some s than in others (fig 6) It had usually started some distal to the anastomosis, and the extent of the bowel affected varied, but in no case did the necrosis encroach on the anastomosis

Sections from the wall of the bowel in the diseased portions show that the necrosis is limited to the mucosa and that the submucosa is relatively normal (fig 7 Further, although the superficial layers of the mucosa glands have died, there are numerous little patches of surviving basal cells (fig 8) In other words, the condition is analogous to partial thickness skin loss and is equally recoverable

Cellular infiltration is remarkably slight and consists largely of cells of the histiocyte and lymphocyte series, polymorphs being scarce The appearance of the submucous and muscular layers is normal (fig 9)

In 8 cases either the stools in vivo or the small-bowel content post mortem were examined bacteriologically In 2 (cases 4 and 10) no pathogens were found in the stool The small-bowel contents were cultured post mortem in cases 1, 5, and 7, and grew *Bacterium mucosum capsulatum* and enterococci, hæmolytic streptococci, and proteus respectively *Staphylococcus aureus* was found in the small-bowel contents in cases 3 and 8, and in the stools of case 9 Cases 8 and 9 occurred within a week of each other but with different surgeons and in different wards The organisms from these 2 cases were typed and found to be 52A and 6/47 respectively Stools were obtained from 14 patients in the same ward as case and cultured on a salt containing medium In 6 *Staph aureus* was grown and typed, yielding three of 52A, two of 76/77, and one of 6/47 Stools from ward-mates of case 9 yielded two positive cultures of staphylococci but unfortunately were not typed

The stomach and small bowel and nose of case 9 were swabbed at the time of operation None of these swabs yielded *Staph aureus*, though her stools yielded staphylococcus during the acute episode. There was no organism common to all the cases, and staphylococci of the same phage type were not uncommon in unaffected patients

It seems likely, from the very heterogeneous collection of organisms obtained, that they are in fact incidental

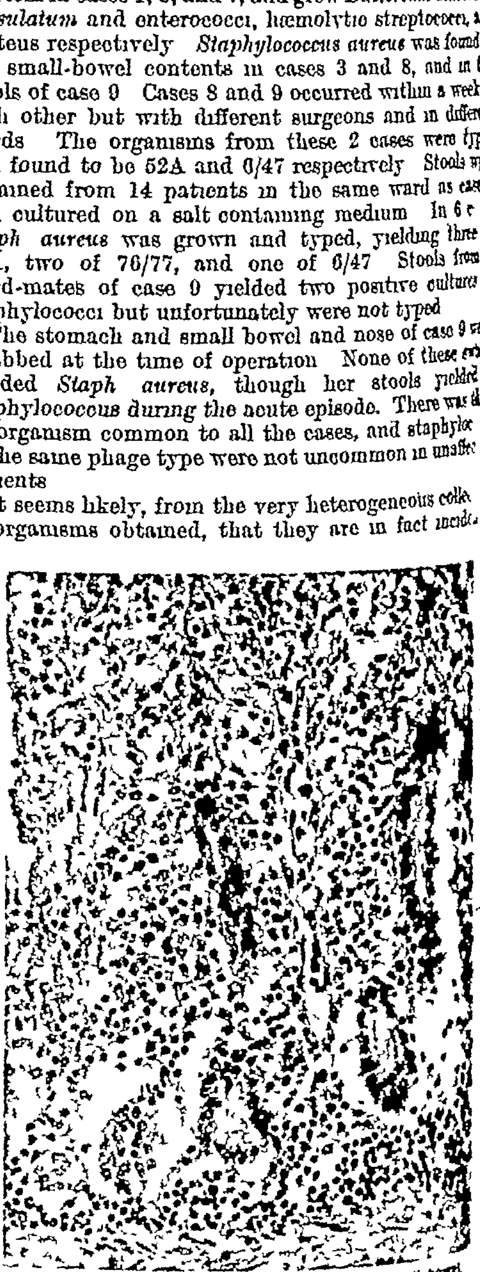

Fig 9—Section of deeper portion of submucosa of small bowel showing predominance of round cells and absence of pol (Hæmatoxylin and eosin × 230)

ANALYSIS OF CASES

Sex	Age (yr)	Disease	Preoperative drugs	Operation	Postoperative drugs	Day of onset of symptoms	Culture of stools	Result
M	51	Gastric ulcer	Sulphamerazine	Billroth I	Sulphamerazine	3rd	*Bact. mucosum capsulatum* and enterococci	Died
M	38	Gastric retention following vagotomy and gastro-enterostomy for duodenal ulcer	Sulphamerazine	Polya type	Nil	2nd	Not cultured	Survived
M	47	Duodenal ulcer	Sulphamerazine	Vagotomy and gastro-enterostomy	Penicillin	2nd	*Staph. aureus*	Died
M	44	Gastric ulcer	Nil	Billroth I	Penicillin	3rd	Not cultured	Survived
M	30	Duodenal ulcer	Nil	Polya type	Nil	4th	Hæmolytic streptococci	Died
M	43	Gastric ulcer	Nil	Polya type	Nil	3rd	Not cultured	Survived
M	65	Gastric ulcer	Sulphamerazine Penicillin	Billroth I type	Penicillin	2nd	Proteus	Died
M	54	Gastric ulcer	Nil	Polya type	Streptomycin	3rd	*Staph. aureus*	Died
F	53	Carcinoma of stomach	Nil	Polya type	Streptomycin Penicillin	2nd	*Staph. aureus*	Survived
M	61	Gastric ulcer	Nil	Polya type	Nil	3rd	*Staph. aureus*	Survived

d not an ætiological factor in the enteritis, a supposition pported by the histological picture which is not that an acute infection. Nevertheless antibiotics should bably be given if only to protect the denuded bowel ing

TREATMENT

ince the primary pathological lesion is a surface truction of the mucosa of the small bowel followed a massive exudation and loss of fluid into the lumen essential disturbance in these patients is dehydration e total fluid loss may of course be very much greater n that suggested by the volume of vomit or fluid ols since the distended bowels may contain several es. Indeed case 8 was severely shocked from dehydra n for eight hours *before passing a fluid motion*

he emergency treatment is to replace intravenously lost water as rapidly as possible, along with sufficient s or glucose to render it isotonic The fluid volume uired may be very large, and the sign that sufficient eing given is the clinical improvement in the patient. blood pressure rises his temperature and pulse rate and he becomes more coöperative and less cyanosed ce the infusion may be running at the rate of up to tres an hour it is easy to overload with sodium A table plan is 1 litre of physiological saline solution to itres of 5% dextrose until rehydration has been ered. After this, hæmatocrit readings and estimations erum-electrolytes (sodium chloride, and potassium) show what extra ions, if any should be given to ect the balance There is also loss of protein which be corrected by transfusions of blood or plasma, and s probably wise to incorporate at least 2 pints of um in the initial phase provided this does not rfere with the rapidity of infusion

nce a balance has been achieved the emergency has sed, and fluid requirements can then be estimated in normal way

RELATED CONDITIONS

enner and Bernheim (1939) and Penner and Drucker a (1948) describe a condition which appears to be y similar to the one described here and follows various rations and is also found in medical cases—i.e., petic coma In particular they record 2 cases following trectomy which are readily comparable to the present es. In both of them the blood pressure fell considerably ing the operation (to 48/30 mm Hg and 80/50 mm and they regard this as an ætiological factor They believe that the mechanism is a compensatory spasm in the vessels of the submucosa giving rise to multiple focal areas of necrosis. They describe patches of local œdema in the submucosa with dilated capillaries, progressing to extravasation, and necrosis of the overlying tissue. In our series significant falls in blood pressure did not occur during operation, except in cases 2 and 5 Also in our histological material the changes in the submucosa consist only in dilatation of the capillaries and these appear to be secondary to the other changes rather than primary

Dixon and Weismann (1948) described 23 cases, in 15 of which, however, the picture is confused by the presence of peritonitis In the remainder an analogous condition seems to have followed colonic surgery The intestinal lesions tended to be more widespread often involving the œsophagus and colon, and the onset of the complication was rather later We have been unable to trace any similar cases at this hospital. Many of Penner's cases seem to belong to this group also

Another condition which clinically resembles the present cases is the epidemic necrotising enteritis which occurred in the summer months in North west Germany after the war (Fick and Wolken 1949)

> Severe cramping epigastric pain comes on suddenly in a previously fit person, and is associated with profound circulatory collapse. The patient may die in twenty four hours; if he survives longer he will have profuse bloody diarrhœa
>
> The necropsy findings in the small intestine differ considerably from those of our cases, for the jejunum is turgid and sausage-shaped with a bright-red serosa. The swelling is due to gross œdema, which also reduces the lumen.
>
> The mucosa forms similar sloughs and histologically seems to be analogous. In these cases the necrosis goes deeper and may lead to perforation with peritonitis. Recovery is complicated by stenosis.

Two similar cases have been described in England (Greville Young 1949 Calnan 1950) Suggested ætiological factors are (1) malnutrition, which is not applicable to our cases with the possible exception of cases 9 and 10 and (2) acute infection due to *Clostridium welchii* type F (Zeissler and Rassfeld Sternberg 1949) No investigation on these lines was made in our cases.

ÆTIOLOGY

The ætiology of the present series of cases is obscure. Most of the patients were fit and well nourished before operation. Apart from 2 cases there were no operative difficulties and no gross fall in blood pressure The conditions for which operation was performed were various (see table) Some of the patients had sulphonamides and antibiotics preoperatively, but most did not Some of them had antibiotics postoperatively and some did not The patients were operated on by eight different surgeons using different techniques The sparing of the gastric mucosa and that of the jejunum or duodenum adjacent to the stoma is constant and seems to exclude operative trauma as a starting point for the necrotising process At least 1 operation was done without clamps All types of suture materials were used The patients were nursed in different wards, and the operations were done in different theatres The bacteria flourishing in the small bowel were of different types, but the clinical picture and necropsy findings remain extremely constant

Although the ætiology is unknown, the clinical picture is sufficiently characteristic to provide the diagnosis and to indicate treatment which, if adequate and prompt, will ensure a happy outcome in a desperate condition

Summary

Ten cases are described in which a characteristic syndrome developed after gastric surgery

Five of the patients died, and necropsy showed that, in all of them, the small intestinal mucosa had sloughed over a considerable area

The diagnosis, treatment, and ætiology are briefly considered

Our thanks are due to those members of the staff of St Thomas's Hospital who have given permission for us to include some of their cases

GROWTH OF CLOSTRIDIUM WELCHII IN THE STOMACH AFTER PARTIAL GASTRECTOMY

J W Howie
M.D Aberd
PROFESSOR OF BACTERIOLOGY

I B R Duncan
M B Glasg
SENIOR HOUSE OFFICER IN BACTERIOLOGY

Lois M Mackie
B Sc. Glasg
ASSISTANT IN BACTERIOLOGY

From the Bacteriology Department of the University and Western Infirmary of Glasgow

During the first week after the operation of partial gastrectomy, often between the third and fourth days, a few patients develop diarrhœa which is usually mild and ceases within twenty-four hours, but is occasionally more severe In attempts to discover a bacteriological cause for the diarrhœa, the fæces of such cases were repeatedly examined in this laboratory without disclosing the presence of specific intestinal pathogens During the past few months examination of the stools and paired sera of 5 cases of diarrhœa after gastrectomy failed to reveal any evidence that the diarrhœa might be due to serological types of *Escherichia coli* associated tro-enteritis

Recently, we were impressed by the similarity of the clinical symptoms of post gastrectomy diarrhœa and of the gastro enteritis caused by food poisoning with heat-resistant *Clostridium welchii*, type A (Hobbs et al 1953, Oakley and Warrack 1953) We did not find heat-resistant *Cl welchii* in the fæces of patients after partial gastrectomy, whether they had diarrhœa or not, but we found numerous *Cl welchii* during the first week after partial gastrectomy in the stomach contents of 11 of 15 patients examined Moreover, in 8 of the 15 patients filtrates of the stomach contents contained detectable amounts of the α toxin of *Cl welchii* Such an observation does not appear to have been made before, so we think it worth recording a brief account of our findings at this stage

Material and Methods

Patients

All 15 patients were in the wards of the Western Infirmary of Glasgow under the charge of Prof C F W Illingworth Through his coöperation and the ready assistance of his medical and nursing staff specimens of stomach contents were collected and sent at once to the laboratory for examination Of the 15 patients 12 had partial gastrectomy, with retrocolic anastomosis of the stomach remnant to the jejunum, for gastric or duodenal ulcer, 2 had the same operation for the same cause but with antecolic anastomosis, and 1 had a total gastrectomy with retrocolic anastomosis for carcinoma of the stomach Only 1 of the 15 patients suffered from postoperative diarrhœa, the patient affected having four loose motions on the third day and three on the fourth day after operation None of the others showed any unexpected signs or symptoms during convalescence and all recovered from the operation After operation a Ryle's tube was left in the stomach which was aspirated by continuous suction for twenty-four hours, during which period only water was taken by mouth During the next twenty four hours diluted boiled milk was given by mouth, thereafter undiluted boiled milk was given

Specimens from Stomach

Specimens from the stomach were aspirated by a syringe attached to the proximal end of a Ryle's tube. 5–20 ml of fluid mixed with mucus was generally obtained, but 7 specimens from 6 patients could be withdrawn only after 5–10 ml. of saline had first been injected into the stomach through the tube In all, 28 specimens were collected from the 15 patients between the first and fourth days after the operation of partial gastrectomy

Films and Cultures

The specimens of stomach contents were centrifuged and films of the deposits were examined by Gram's method, a few were also examined by the eosin method for the demonstration of capsules One loopful of each deposit was spread on each of two blood-agar plates which were incubated at 37°C, one aerobically and the other anaerobically in a McIntosh and Fildes jar One drop (cases 1–6) or several drops (cases 7–15) were also inoculated into a tube of Robertson's meat broth, which was put in the incubator under ordinary atmospheric conditions

Determination of pH

The pH of each sample of stomach contents was determined by indicator papers checked at frequent intervals with a glass electrode and a Doran pH meter

Examination of Filtrates for Welchii Toxin

The supernatant fluid of the centrifuged stomach content was passed through a Seitz sterilising or clarifying (F C B) disc and examined for welchii α toxin by the lecitho vitellin (L V) and the hæmolytic tests, the methods followed being those described for culture filtrates by Oakley and Warrack (1953) f the fluid was more acid than pH 6·5 a few drops of N NaOH were added to bring the reaction between pH 6·5 l 8·0. If the fluid was hypotonic as roughly tested by ding a loopful on a slide with a loopful of red-cell suspension, Cl was added to make it isotonic. 1 ml. of filtrate of the mach content was then put into each of 4 tubes. Of se tubes 1 and 3 received also 0·5 ml. of saline and tubes 2 l 4 received 0·5 ml. of *welchii* α antitoxin diluted to contain units per ml. To each of the 4 tubes 0·5 ml. of borate fer saline with calcium chloride and peptone was added contents were mixed and the tubes were left on the bench 30 minutes. The composition of the borate buffer saline in 1 litre of distilled water) was: borax 3·55, boric acid 5, sodium chloride 0·2, calcium chloride 0·5, and peptone 0. The pH was 8·0–8·4. Tubes 1 and 2 then received ml. of L.V. suspension; tubes 3 and 4 received 0·5 ml. washed sheep red cells suspended (6% suspension) borate buffer saline. The tubes were then incubated in a ter bath at 37°C for one hour and read after standing over ht on the bench at room temperature. The filtrate was orded as containing *welchii* α toxin if tube 1 showed opacity tube 3 showed hæmolysis or if hæmolysis and opacity re both observed. Tubes 2 and 4, the control tubes taining antitoxin, showed neither opacity (tube 2) nor molysis (tube 4).

Culture filtrates of *Cl. welchii* isolated from the mach contents were titrated for *welchii* α toxin by molytic and L.V. tests by the methods described by kley and Warrack (1941).

titoxin in Patients' Sera

Paired sera were taken from 13 patients, the first ecimen on the day before operation and the second between the seventh and tenth day after operation. After being heated at 56°C for 30 minutes they were examined for *welchii* α antitoxin by the methods described by Oakley and Warrack (1941).

Results

The results of our examinations, which could not be correlated with any particular clinical symptoms, signs, or events, are summarised in table I.

Presence of Cl. welchii

Direct films of the centrifuged deposits of the stomach contents of 12 of the 15 patients and 17 of the 28 specimens contained many gram-positive rods which sometimes appeared singly but more often in clumps and short chains. Many of the forms were relatively short and stout, about 3–4 × 1 µ. Their appearance suggested a diagnosis of *Cl. welchii*, a possibility which was strengthened when the first specimens were examined and found to have capsules surrounding the bacilli. Cultures on the positive anaerobic blood-agar plates yielded typical *Cl. welchii* colonies surrounded by zones of clearing. The identity of the organisms was confirmed by their production of *welchii* α toxin in broth subcultures. So far the organisms have not been examined for production of other *welchii* toxins or for the heat-resistance *of their spores in cultures. Heat-resistant Cl. welchii* were not found in the fæces of a few cases examined for this point.

Demonstration of Cl. welchii *α Toxin in the Stomach Contents*

When films and cultures revealed the presence of *Cl. welchii* in the stomach contents, the question arose whether the organism was merely a transient or whether it must be regarded as colonising the stomach remnant. In considering this point it was obviously of interest to discover if toxin was produced, and our findings show that it was. The stomach contents of case 4, that of the only patient who suffered from postoperative diarrhœa, did not yield demonstrably more toxin than the stomach contents of the others who had no diarrhœa.

Table I shows that the L.V. test was positive in only 3 of the 10 specimens in which toxin was demonstrated. The first specimen from case 14 contained lysed blood and so could not be used for a hæmolytic test; it gave a positive L.V. reaction. 2 positive filtrates were diluted and examined by the hæmolytic test to find how much toxin they contained. Evidently the amount was only about 1 minimum hæmolytic dose per ml., because even when diluted only 1 in 2 these filtrates yielded a negative result. Not enough filtrate was available from other positive specimens to titrate them in this way. The 2 specimens which gave a positive L.V. test and could be examined by the hæmolytic test were positive by that method also. The low ratio of positive L.V. tests to positive hæmolysin tests is probably explained by the small amounts of toxin present, for on titrating filtrates of subcultures of six of the isolated strains we found that the hæmolytic test as carried out

with borate buffer saline containing added calcium
chloride and peptone was a more sensitive indicator
than the L V test The details of toxin production by
these six strains (table II) show that the strains were not
ery active producers of α toxin The amounts pro-
uced may be compared to those found by Evans (1945)
r two strains from the human intestine—namely,
e α antitoxin equivalent of 0 05 and 0 03 unit per ml
obbs et al reported that their food poisoning strains
of Cl welchii, type A, produced only small amounts of
toxin in culture—never more than the equivalent of
one α-unit per ml and usually far less

Antitoxin in Patients' Sera

As already described, the sera of 13 patients were examined for *welchii* α antitoxin before and from seven to ten days after operation Titration was done by the hæmolytic method and the results were negative in that none of the sera showed as much as 0 002 unit per ml, the smallest amount measured by our tests Through the kindness of Dr C G Paine, Jessop Hospital for Women, Sheffield, we also examined serum taken from a woman eleven days after the onset of a severe post-partum infection with *Cl welchii* This serum contained only 0 005 unit of *welchii* α antitoxin per ml In the light of this low value after a severe infection the negative results in our patients are not surprising, particularly in view of the small amounts of toxin which we found in filtrates of their stomach contents

Discussion

The starting point of the present investigation was our inability to identify a bacterial cause for the diarrhœa, usually mild and transient, which sometimes complicates convalescence during the first week after partial gastrectomy Our results now show that this operation influences events within the human alimentary tract in such a way that *Cl welchii*, a normal inhabitant, may grow and produce detectable amounts of α toxin within the remnant In food-poisoning due to
the type normally found i
observations and references
establish that the symptom
type and duration to those
develop diarrhœa after gastre
significance of our observations it test the clinical
worth giving a dose of *Cl welchii* antitoxin to patients who would probably be about to undergo the operation of gastrectomy Analysis of the postoperative records of a series of cases given antitoxin compared with those of comparable cases not given antitoxin, together with the results of bacteriological examination, would probably show whether the growth and toxin production by *Cl welchii* after gastrectomy have any clinical significance or none Admittedly we found only small amounts of toxin in the stomach remnant, of the order of one hæmolytic dose per millilitre, and toxin was detected in only 8 of the 15 patients examined, but two points may be noted in this connection The first is that 7 of the 28 specimens examined were diluted with saline solution to withdraw them and that only 1 of these was found to contain toxin Since dilution of known positive specimens even to only 1 in 2 was enough to give a negative hæmolytic test, the dilution may be regarded as weighting events against our finding toxin in these specimens Moreover, the single positive among the diluted specimens was detected only when we used a Seitz clarifying (F C B) instead of a sterilizing (S B) disc, which we had previously employed Later, on passing through a Seitz S B disc 7–9 ml volumes of diluted toxin containing 20 or 100 minimum hæmolytic doses (M H D) per ml, we found that less than 1 M H D per ml appeared in the filtrate Even with an original concentration of 1000 M H D of toxin per ml the
so filtrate contained only 40 M H D per ml Use of

the F C B disc reduced the concentration from 20 to
M H D per ml, filtration through a 'Gradocol' membra
of 0 9 μ average pore diameter left the concentr
of toxin unchanged The second point is t
number of organisms and amount of toxin a
likely to be much greater in the ileum th

Much of the earlier work suffered from
difficulties of demonstrating and measuring *welchii*
and its antitoxin and of legitimate doubts about
interpretation of some at least of the results—diff
and doubts now able to be resolved by the
of the hæmolytic and lecitho vitellin
seems to us that our evidence makes a case
the position again

Summary

In 12 of 15 patients examined during the fir
the operation of partial gastrectomy numerous
welchii were found in films and cultures from t
contents In 8 of the 15 patients small
welchii α toxin were also demonstrated in
specimens

It would probably be worth investigatin
influences favour the development of *Cl welch*
gastrectomy and whether there is any clinical sig
in growth and toxin production by the
the circumstances described

The use of the hæmolytic and lecitho-vitellin
of titrating *welchii* α toxin and antitoxin could
many of the difficulties of technique and doubts
interpretation associated with earlier work which
to establish the rôle of *Cl welchii* as a human
pathogen

We are grateful to Prof C F W Illingworth for dr
our attention to this problem, to Professor Illin
medical and nursing staff for their trouble in collecting
mens for us, particularly to Mr J K Watt whose

the work was of great value, especially at its beginning Miss Mollie Barr Mr H. Proom and Prof. C. L. Oakley gifts of standard materials and for helpful information methods; to Dr Joan Taylor for examining strains of coli; and to the Medical Research Council and the nkin Fund for grants towards the expenses of the estigation.

CHÆMIC NECROSIS OF THE STOMACH

FOLLOWING SUBTOTAL GASTRECTOMY

A G RUTTER

M.B. N.Z F.R.C.S E., D T.M & H

CONSULTANT SURGEON QUEEN MARY S HOSPITAL, ROEHAMPTON

F the many possible complications of subtotal gas tomy one is so rarely described that few surgeons sider it in planning their operation This complication schæmic necrosis due to over enthusiastic devascular ion of the proximal part of the stomach Careful ch has revealed no reported instance of this com ation during the past twenty years The following rt of a fatal case is a reminder that the blood supply he stomach cannot be interfered with so lightly as ent teaching might lead one to expect.

Case record

he patient was a man, aged 40 who had had intermittent epsia of characteristic ulcer type since 1945 Gastric r had been demonstrated radiographically in 1946 and ad had two periods of thorough inpatient medical treat t in other hospitals Each period of treatment had ight about remission followed after a few months by rrence of symptoms. Severe symptoms began again at nd of 1952; these did not respond to treatment at home he was admitted to Queen Mary s Hospital, Roehampton, Feb 18 1953

he patient was well built and healthy looking, with signs ild chronic bronchitis He was having severe almost inuous epigastric pain radiating through to the back. was sleeping poorly on account of the pain, which was not ved by taking either food or alkali The upper abdomen tender and muscular rigidity was quite distinct After a days on a régime of sedatives and two hourly milk feeds, pain was less severe; X ray examination now showed a deep ulcer high up on the posterior wall of the stomach. ther medical treatment including later an intragastric produced only very incomplete relief of his pain and rgical treatment was decided on.

operative biochemical examinations showed normal es for blood urea, chlorides, and protein and a red d-cell count of 3 000 000 cells per c.mm. with hæmoglobin The anæmia was corrected by transfusion of three s of stored whole blood and protein hydrolysates were both by mouth and parenterally during the days before ation.

eration was done on March 25 under nitrous-oxide/ opropane anæsthesia, supplemented with pethidine and *d* tubocurarine chloride The abdomen was opened through a left paramedian incision, and a large penetrating ulcer of the posterior wall of the stomach was immediately palpated; this formed a hard indurated mass of tissue infiltrating into the lesser omentum almost up to the level of the cardia. Glands in the lesser omentum were soft and fleshy and the lesion was judged to be benign and resectable The duodenum was healthy This was divided but not closed, and the ulcer was dissected off the pancreas with the diathermy knife, leaving a good deal of the ulcer base in situ. The left gastric artery was divided near its origin from the cœliac axis. The whole of the lesser curvature was necessarily removed for the ulcer was close to the œsophago-gastric junction and the greater curvature was very extensively mobilised to allow the gastrectomy to be completed by a Billroth I type of gastro-duodenal anastomosis. A tube drain was placed in the region of the ulcer bed on the pancreas, and brought out through a stab wound in the left flank. The operation was difficult but not unduly so and the patient left the operating theatre in excellent condition

Postoperative Course.—The patient s condition was good until 8 A.M next morning when he complained of severe abdominal pain and rapidly developed the appearance of extreme shock There was no vomiting The abdomen was rigid but not distended. The cause appeared to be either partial dehiscence of the suture line—for which no adequate reason could be adduced—or acute pancreatitis due to damage to the pancreas during removal of the ulcer The patient s condition improved considerably in the next few hours, and his pain diminished so it was decided to treat him conservatively until the diagnosis became clearer

On the second day after operation he was much improved; his pulse rate was still 110–120 per minute but he had little pain and did not seem to be greatly distressed Aspiration through a Ryle s tube yielded only a few drachms of slightly bloodstained fluid

On the third day there was some clear fluid discharge from the drainage tube the abdomen was much softer, but the pulse rate was still 110–120 per min Urinary output and fluid balance (by intravenous infusion of blood saline glucose and protein hydrolysate) were satisfactorily maintained

On the fifth day the discharge from the drainage tube became bile-stained and more copious the pulse-rate had fallen to 100 per min. and the patient s general condition was greatly improved. It was now fairly clear that some dehiscence of the anastomosis must have taken place; but as signs of general peritonitis were absent, and the patient s condition seemed to be improving no immediate surgical treatment was thought to be necessary

On the eighth day there was copious bile-stained discharge from the wound the pulse rate remained about 100 per min., and the patient s general condition was well maintained, though intravenous fluids were still necessary to achieve fluid balance and adequate caloric intake In order to elucidate the question of leakage from the anastomosis, a little dilute barium suspension was given by mouth and radiographs were taken with a bedside portable machine The barium appeared almost immediately in the discharge from the wound and the films showed a diffuse spread of the suspension in the left upper quadrant It was presumed from this that complete dehiscence of the anastomosis must have taken place and a further operation seemed inevitable However within a few minutes of taking the barium the patient suddenly collapsed again, with severe pain and profound shock and operation was obviously out of the question. After administration of morphine and blood transfusion he quite rapidly improved

Next morning—the ninth day after operation—he had apparently recovered completely from the attack The abdomen was soft and the pulse-rate only 96 per min., and he was quite free from pain the discharge from the wound was now very free and still contained traces of barium The sudden temporary collapse was attributed to the irritant effect of the barium suspension on the inflamed peritoneum

At a *second operation* on the evening of the ninth day the left paramedian incision was re-opened. The small bowel was not distended there were numerous plastic adhesions; a localised intraperitoneal abscess containing an ounce or two of pus was present Careful examination of the operation area showed that the duodenum right up to the suture line the stomach was normal and the suture line itself the œsophagus also appeared normal The wh stomach remnant was grey and avascular, and had the consistency of wet blotting paper There was a small perforation on the lesser curvature, and a much larger one on the greater curvature The latter perforation may have been made, or at least enlarged, by the manipulations necessary to inspect the stomach, for the gentlest handling of the stomach produced further tears in its wall No bleeding occurred from these tears Obviously the whole of the remaining stomach wall was necrotic, and any reparative surgery, at least at this stage, was out of the question An enterostomy was established in the first jejunal loop, and a further drainage tube inserted

Postoperative Course —The next day the patient appeared surprisingly well, the pulse rate was 120 per min, he was comfortable, and had passed some urine On the following morning—thirty six hours after the second operation and eleven days after the first—he collapsed, and he died in a few hours Necropsy confirmed the findings at the second operation, the duodenum and the œsophagus were healthy, but the whole of the stomach remnant was completely necrotic

Discussion

All current surgical textbooks describe in detail the blood supply of the stomach, and emphasise the richness of its anastomotic network All of them leave the impression that the arteries supplying the stomach may be divided just as far as is necessary to allow free mobilisation and adequate resection

Somervell (1946), describing his operation of "physiological gastrectomy," advised the division of "five out of six of the small arteries on the greater curvature and as many vessels as possible on the lesser curvature," but did not discuss what might happen if devascularisation were more complete Pannett (1938) advised the surgeon to divide the vessels "until he deems a sufficient length has been denuded, while Finsterer (1939) said that the stomach should be divided a hand's breadth to the left of its midpart, without specifying how far the vessels need be cleared Visick (1948), describing his "*measured radical gastrectomy,*" *stated that all but one* of the vasa brevia, and in certain cases all the vasa brevia, are to be divided, and he specified that "the line of section is made so as to leave a small *devascularised* remnant"

None of these workers suggest that there may be any danger in carrying the division of the vessels too high up the greater curvature The modern trend in gastrectomy has been towards higher and higher resections, and towards the removal of very high ulcers which might more safely be treated by resection below the ulcer (Wells 1933) Thus Hinton and Localio (1950), describing the technique of an operation for very high lesser curve ulcer involving the construction of a tube of greater curvature for anastomosis to the duodenum, say that "the greater curvature should be freed beyond the entrance of the short gastric vessels along the gastro lienal ligament, and the lesser curve freed as far as the œsophagus Unless this is done the tube cannot be constructed" The present case *suggests that for certain* patients this may be very dangerous advice

Experimental work in dogs indicates that there are well-defined limits to the devascularisation which the stomach will tolerate Le Veen (1948) found that total ligation of the main vessels in 30 dogs led to diffuse infection of the stomach wall in 4, and to the development of ulcers, presumably ischæmic in origin, on the greater curvature in 6 others Layne and Bergh (1943) found that ligation of *all four main arteries* caused gangrene of the middle two thirds of the stomach The most detailed study is that of Bernheim (1932), who showed that either the lesser curvature or the greater curvature may be totally devascularised without ill effect, as may the whole of one curvature and part of the other, but if *all* vessels are tied, gangrene develops—and when this develops it is always on the greater curvature

The only references I have found to the possibility of ig in surgical procedures in man are both over twenty years old Barber (1933) suggested that "abnormal stomachs and in individuals with impe circulation and poor neuro muscular tone," too devascularisation may lead to necrosis and Sm (1931) wrote "perforation may occur as a result impaired blood supply, and its frequency is in relation with the level of resection In high resectio wide berth must be given to the remaining blood s on the greater curvature" In no modern article resection which I have read is this danger empha or, indeed, mentioned

Probably in the ordinary standardised gastre for duodenal or lesser curve ulcer, there is no dange ischæmic necrosis But in elderly patients with genera arteriosclerosis, and especially in high resections highly placed ulcer requiring the construction of a of greater curvature for anastomosis, the danger may real In such cases the blood supply to this greater curvature should be carefully considered, at least the uppermost vas breve should be jea safeguarded, even at the expense of free mobilisa avoid this disaster, which is virtually irreparable

I have to thank the chief medical officer, Ministry of for permission to publish this report

HUMIDIFICATION IN POSITIVE-PRESS RESPIRATION FOR BULBOSPINAL PARALYSIS

John Marshall
M D Manc, M R C P
D.P M

J M K
M A, D.M Oxfd
M.R C.P

RESEARCH ASSISTANTS, DEPARTMENT OF NEUROLOG
UNITED OXFORD HOSPITALS

The use of positive-pressure respiration tracheal tube in the treatment of bulbospinal requires adequate humidification of the air or gas need was emphasised by Lassen (1953) from his in the 1952 epidemic of poliomyelitis in Cop "a good humidifier is essential, otherwise secretion may occur" We describe here a which has proved itself satisfactory in clinical use open-circuit positive pressure system and can used in a closed-circuit system

The minimum level of humidification necessa avoid incrustation of secretions is uncertain, seems reasonable to reproduce as far as possible conditions existing in normal man when br through the nose

Perwitzschky (1927), in a most careful study, that when room air 40% saturated at 25°C was through the nose, the relative humidity in the lowe of the trachea was 98% and the temperature When the air was inhaled through a tracheotomy however, the relative humidity in the trachea was 51% These findings suggest that the aim in pressure respiration should be to deliver air throu tracheal tube at 36°C and 100% relative humidity

The technical requirements of positive pressure tors impose limitations on the methods of ilable. If positive pressure pumps such as the ıver (1953) respirator and the Radcliffe respiration nps A and B (Russell and Schuster 1953) are used l the humidifier is placed on the inspiratory side the pump cooling in the pump leads to condensation hin it and to eventual failure. Hence the humidifier st be placed between the pump and the patient is means that the humidifier must have a low resistance he desirable safety precaution of the pump working a low pressure is to be maintained In addition the midifier must be safe for the patient, require very le attention and be simple and cheap in design th these considerations in mind we experimented with eral methods of humidifying air and oxygen

Methods

To test the efficiency of various methods of humidifica n, wet bulb and dry bulb thermometers were placed a small well lagged glass jar through which air mped through the humidifier was led through rugated breathing tubing 3 ft long and lagged with ton wool 2 cm thick There was free exit from the so that the wet and dry bulbs were in a moving eam of air

Observations

sing Air Through Water

The first method to be tested was the time honoured of bubbling gas through water A common practice o bubble through about 4 cm of water in a Woulfe s tle at room temperature, but experiment shows that bbling air through as much as 15 cm of water at 46 C l humidify 3 litres of air per minute to the extent of y 87% The high resistance of this method and the ure to achieve 100% humidity led to its being ndoned

sing Air Through Wet Gauze

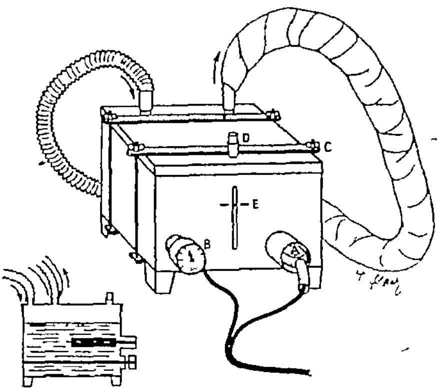
The next method in common use which was tested to pass the air through wet gauze Six litres of a minute were passed through a closed box across ich hung four curtains of wet gauze, each 12 cm are, the lower ends being in water at 41 C This thod achieved a relative humidity of only 70% 37°C

sing Air Over Warm Water

xford vaporiser—Wislicki (1953) recommended the of the Oxford Vaporiser as a combined inflator midifier for positive-pressure respiration Used in way the bellows draw air over water contained in ether chamber and pass it to the patient The mp is thus between the humidifier and the patient, ich is contrary to the principle mentioned above the method was given a trial. When the water ect of the vaporiser was heated to the maximum ording to the normal procedure and the ether con ler filled with water at an initial temperature of 90°C air was 100% humidified but its temperature could be maintained above 22 C This was due to the t degree of cooling taking place in the bellows. at 22 C is too cold for direct injection into the trachea, moreover air which is saturated at 22 C is only % saturated when warmed to 36°C

ew apparatus—Another apparatus (see figure) then built incorporating the same principle of passing over warm water but placing the pump before the midifier

his consisted of a water bath heated with an electrical ter (A) and controlled by a thermostat (B) The bath an airtight lid capable of withstanding an intermittent sure of 30 cm. of water The bath was rigid, and its was secured with clamps (C) compressing a gasket Air led into and out of the bath through two ⁷/₈ in brass es passing vertically through the lid and joined to lengths of corrugated breathing tubing A third brass tube (D) in the lid, occluded with a rubber bung was provided for filling the bath, and a window (E) in the side enabled the water level to be observed The level was such that there was about 5·5 litres of air above the water and the area of water over which the gas passed was 900 sq cm.



The apparatus: A plug of electric heater; B thermostat C, clamp; D water inlet; E window

This apparatus was tested both experimentally and clinically Experimentally air at 100% relative humidity could be delivered at temperatures up to 49°C which was the highest temperature tested When used clinically with the thermostat set at 50°C the air, after passage through a tube lagged with 2 cm of cotton wool and through the connections to the tracheotomy tube including an automatic spill valve, had a temperature of 35°C and a saturation of 100% The precise adjustment of the thermostat depends on the efficiency of the lagging of the breathing tube and the amount of heat lost in the connections to the tracheal tube before the air reaches the patient.

The influence of variations in the minute volume on the temperature and saturation of the delivered air was explored The results are given in the accompanying table from which it can be seen that these variations produced negligible changes in the temperature of the air until the minute volume was reduced to 3500 ml which is about half the minute-volume of the normal resting adult This is of considerable practical importance because once the thermostat was set for a certain delivery tube and connection no further adjustment was necessary when the stroke or minute volume was altered to the needs of the patient Likewise no adjustment was required when changing from room air to 100% oxygen

The only attention the apparatus required was the addition of a little water every twelve hours The use of a spring loaded plug for the heater obviated any danger from switching on the heater with the

EFFECT OF VARIATIONS IN MINUTE VOLUME ON TEMPERATURE AND HUMIDIFICATION OF AIR

Min. vol. (ml.)	Stroke vol (ml.)	Rate per min.	Temp. of thermostat (C)	Temp of air (°C)	Humidity (%)
20,000	1000	20	49	34 5	100
12 000	500	24	49	34 5	100
10,000	500	20	49	35 0	[illegible]
7000	500	14	49	34 5	[illegible]
3500	250	14	49	33·0	[illegible]

humidifier empty There was no danger of the water being inhaled, because the outlet tube went vertically through the lid of the water-bath and was well above the water level Since the humidifier stood on the floor and the breathing-tubing led up to the patient's bed, there was no possibility of spill, and water condensed in the tube ran back to the humidifier The resistance of this apparatus when transmitting 20 litres a minute in fifteen strokes was less than 3 cm of water Cultures of the air after its passage through the humidifier showed that it introduced no pathogens

In practice a humidifier of this size (30 cm square) was not inconveniently bulky The size can, however, be reduced by connecting the inlet and outlet tubes within the humidifier with a tube of sponge rubber 45 cm long and 2 cm internal diameter This can be made by sewing together the edges of a strip of 'Dunlopillo' 1 cm thick The sponge-rubber dips in the water and, when saturated, provides an adequate surface for vaporisation

Discussion

These observations emphasise the importance of measuring the effectiveness of clinical methods of humidification before putting them into use Though the time honoured methods of bubbling gas through water, or passing it through wet gauze, add some moisture, they are entirely inadequate if 100% humidification is desired In the present state of knowledge it seems reasonable to reproduce as closely as possible the conditions known to obtain in normal man, since the dangers of incrustation due to drying are well established and serious

The humidifier and heater described here is well suited for positive-pressure respiration It will humidify air or pure oxygen up to 100% saturation at a wide temperature range around body-temperature, it will deal with 20 litres of gas per minute, which is well in excess of normal requirements, and it does not require adjustment for changes in minute-volume The resistance of the apparatus is low, and the attention it requires minimal

This apparatus has had a thorough clinical trial, it has been used for four weeks for a patient on positive pressure respiration with satisfaction The secretions were always moist and could easily be removed from the trachea by suction through a fine catheter Viscid tenacious mucus and dry crusting in the trachea were not observed The patient appreciated the machine's action because, when it was removed from the circuit, she complained of discomfort

This simple piece of apparatus can be made in any hospital workshop at low cost, and can be recommended for extensive clinical use

Summary

Several commonly used methods of humidifying gas were found to be unsuitable for clinical use if 100% humidification is desired

An easily made apparatus is described which will humidify gas to 100% saturation at body-temperature, and can be used in positive pressure respiration

We wish to thank Dr W Ritchie Russell and Dr A Crampton Smith for their encouragement with this work, and Dr H G Epstein, of the Nuffield department of anæsthetics in the University of Oxford, for his advice One of us (J M) was in receipt of a grant from the Medical Research Council

Preliminary Communication

EFFECT OF AN ANTI-THYROXINE COMPOUND ON THE METABOLISM OF RADIOACTIVE THYROXINE AND TRIIODOTHYRONINE IN RATS

IN previous communications (Maclagan, Sprott, Wilkinson 1952, Maclagan and Wilkinson 1952) it been suggested that the anti-thyroxine compound, 4 hydroxy 3 5 diiodobenzoate (B.H D B) owes its i bitory effect to interference with the deiodination thyroxine to triiodothyronine, the latter probably r senting the metabolically active form of the th hormone (Gross and Pitt Rivers 1952, 1953, Gross Rivers, and Trotter 1952) The enhancement of the of triiodothyronine by simultaneous treatment B H D B may also be explained on this assumption, if triiodothyronine is further deiodinated to p inactive substances, then interference with this p would increase its metabolic effects

In order to test this hypothesis, the urinary iodi rats treated with thyroxine labelled in the 3' 5' pos with ^{131}I was compared with that of animals B H D B in addition to similar doses of labelled th Two groups of 3 rats, each weighing 230 ± 20 g given oral suspensions of B H.D.B (50 mg per ml pe in 1% aqueous carbomethoxycellulose on the first 25 mg per 0 5 ml per rat on each succeeding day experiment Two further groups of 3 rats received medium only On the second day the rats in all groups each received a single subcutaneous inje the thyroxine solution (0 5 ml 0 02N Na_2CO_3 100 µg , 67 µc thyroxine per rat) Each group placed in a metabolism cage and the urine and collected daily After suitable dilution, the radioa in each was measured and the results expressed a percentage of the dose administered

TABLE I—EFFECT OF B H D B ON URINARY IODIDE OF R TREATED WITH THYROXINE

Groups of 3 rats treated with	Percentage of dose excreted after	
	48 hours	120 h
Thyroxine (4 µg /rat)	11 8 16 7	[illegible] [illegible]
Thyroxine (4 µg /rat) + B.H D.B *	6 1 4 8	[illegible] [illegible]
Thyroxine (100 µg /rat)	12 5 12 4	[illegible] [illegible]
Thyroxine (100 µg /rat) + B H.D.B *	3 2 3·0	[illegible] [illegible]

* See text for dosage of B.H D.B

TABLE II—EFFECT OF B.H.D.B ON URINARY IODIDE OF TREATED WITH TRIIODOTHYRONINE

Groups of 3 rats treated with	Percentage of dose excreted after	
	48 hours	[illegible]
Triiodothyronine (6 µg /rat)	21 3 20 7	[illegible] [illegible]
Triiodothyronine (6 µg /rat) + B H.D B *	5 2 9 4	[illegible] [illegible]
Triiodothyronine (30 µg /rat)	18 4 31·6	[illegible] [illegible]
Triiodothyronine (30 µg /rat) + B.H D.B.*	6 3 8·0	[illegible] [illegible]

* See text for dosage of B H.D B

A similar experiment in which 4 µg doses of thyroxine ere given was also performed The results of both xperiments appear in table I

Further experiments in which triiodothyronine labelled n the 3 position with ^{131}I was given in doses of 6 µg nd 30 µg per rat in place of thyroxine were also carried ut The results of these are summarised in table II

It is clear that when given simultaneously with hyroxine or triiodothyronine B.H.D.B reduces the xcretion of urinary iodide in intact rats. Thus support given to the hypothesis that it owes its action to terference with processes of deiodination of these two omponents of thyroid secretion.

Part of this work has been briefly described (Wilkinson nd Maclagan 1953) and a fuller report will appear ewhere (Wilkinson et al 1953) These results in tact rats are at variance with those of Roche Deltour, nd Michel (1953) who found that in thyroidectomised ts B.H.D.B actually increases the rate of deiodination f thyroxine labelled in the 3′:5′ positions with ^{131}I It ould be premature to discuss the cause of this apparent ontradiction, but it seems that the mode of action of B.H.D.B may be entirely different in intact and thyroidectomised rats

The radioactive thyroxine was obtained from the Radiochemical Centre Amersham, and the radio triiodothyronine was prepared from 3:5-diiodothyronine kindly provided by Glaxo Laboratories Ltd.

Reviews of Books

iuretic Therapy

Pharmacology of Diuretic Agents and Clinical Management of the Edematous Patient ALFRED VOGL, M.D assistant professor of clinical medicine New York University College of Medicine Baltimore: Williams & Wilkins London: Baillière Tindall & Cox 1953 Pp 248 38s 6d

THOUGH the title of this book may suggest another llestone in the fragmentation of treatment such mis vings are dispelled by A. M Fishberg's foreword, and en more by the actual contents of the book. It is up-to-date balanced and comprehensive review of e methods of relieving oedema

Specific treatment of the underlying disease when available mentioned in outline only; but there is a detailed and ctical account not only of diuretic agents but also of the tionale and effects of low salt diets and cation exchange ins. There are short introductory chapters on the causes oedema, and the pharmacology of diuretic agents but o-thirds of the book is devoted to the practical management oedema. As might be expected of the discoverer of the uretic action of organic mercurials, these are fully dealt th, and there is perhaps no better account available of the arious causes of mercury fastness. The indications for pplementing mercurial diuresis with aminophylline exchange ins, and decholin are considered in detail. In view of the neral high quality of the book, it is surprising to find no ention of carbonic anhydrase inhibitors as diuretics, though lphonamide compounds have been used in this way for me years; a few of the details of treatment reflect American etary habits and facilities.

Most cardiologists and general physicians would find ch in this book to interest them There is a biblio aphy of 725 references not all American

troduction to Functional Histology

GEOFFREY BOURNE, D.SC D.PHIL. reader in histology London Hospital Medical College London: J & A Churchill 1953 Pp 108 21s

Dr Bourne does not set out to provide a textbook of stology but rather to supplement existing books with account which emphasises the functional, rather than e structural, features of cells and tissues. He has ceeded well in his purpose and a wide reading public students medical practitioners, and investigators will grateful to him His accounts are concise and informa ve they are also readable—indeed vivid—so that they splay the complex machinery of the living cell as a ghly organised factory of enzyme operatives, while the ochemistry of the simultaneous cell processes of kata lism synthesis, and respiration are clearly explained he 98 illustrations are carefully selected and instructive: many of them are electron microscope photographs. At the end of the book there is a useful chapter on the more recent histochemical techniques.

Atlas of Tumor Pathology

Fascicle 14: Tumors of the Thyroid Gland. SHIELDS WARREN M.D., professor of pathology and WILLIAM A MEISSNER M.D assistant professor of pathology Harvard Medical School 1953 Pp 97 $1.75

Fascicle 15: Tumors of the Parathyroid Glands BENJAMIN CASTLEMAN M.D acting chief department of pathology and bacteriology Massachusetts General Hospital 1952 Pp 74 65 cents.

Fascicle 17 Tumors of the Lower Respiratory Tract AVERILL A. LIEBOW M.D professor of pathology Yale University School of Medicine 1952. Pp 189 $1.25

Washington, D.C.: Armed Forces Institute of Pathology

Fascicle 14—Dr Warren and Dr Meissner refer to misunderstanding and confusion in classification and in views about the evolution and especially evaluation of thyroid tumours. The opinions of both pathologists and clinicians range from "enthusiastic overestimation to regrettable underestimation" of their potentialities.

The growth habits of these tumours differ from those of other tumours in several respects, for they are subject to variation and even to apparent inconsistencies The authors find that a true follicular adenoma produces symptoms of clinical hyperthyroidism in only about 1% of cases for Graves's disease is usually associated with a nodule showing excessive hyperplasia in an adenomatous goitre Clinical distinction between an adenoma and a carcinoma may be difficult, for surgeons estimates of the incidence of carcinoma in discrete nodules in the gland run as high as 20%. When studied pathologically some of these thyroids will turn out to have adenomatous goitre with multiple nodules. Nevertheless Dr Warren and Dr Meissner say surgical excision is the proper treatment because cancerous change in adenomas may be common. The giant-cell and follicular cancers in particular suggest transition from a follicular adenoma. In the papillary carcinomas, which are commoner evidence of transition is less striking but it is suggested that most of them may be malignant from their inception. Proof is lacking that the hyperplasia seen in Graves's disease sometimes leads to cancer and no increase of cancer seems to be resulting from the hyperplasia induced by thiouracil

This important survey is based on the clinicopathological study of 600 cases of carcinoma of the thyroid and several thousand benign tumours

Fascicle 15—Dr Castleman in his admirable and exhaustive account of the pathology of the parathyroid glands reviews 100 cases of primary hyperparathyroidism from the records of the Massachusetts General Hospital An adenoma was present in 89 of them, the lower glands being involved thrice as often as the upper—whereas in primary hyperparathyroidism not associated with tumour formation it is usually the upper glands which show the greater degree of hypertrophy A fifth of the adenomas were mediastinal Dr Castleman subscribes to the view that recurrences after operation are due to the original invasiveness of the tumour rather than to any accidental spilling of adenoma tissue at operation Although malignancy is rare, the histological assessment of a parathyroid tumour requires to be made with care

The illustrations, conforming to the high level of previous fascicles, include an instructive set of photomicrographs of serial tibial biopsies in a case of osteitis fibrosa cystica taken before and after operation

Fascicle 17 —Dr Liebow gives a full account of tumours of the lower respiratory-tract and pays special attention to what is seen through the bronchoscope and at operation He discusses atypical proliferation but doubts whether carcinoma often develops as a result of metaplasia An illustration of atypical epithelium is included, which, in preparations of sputum, would surely raise the suspicion of carcinoma. Dr Liebow supports the view that adenomas, comprising 6–8% of lung tumours, are derived from the mucus-secreting glands and their ducts Metastases may occur, but they are "rare, sluggish and usually inconsequential" The cylindroid variety seems to show greater invasiveness than the carcinoid

This fascicle includes a useful illustrated account of malignant cells in sputum and in pleural fluids

Slipped Capital Femoral Epiphysis

ARMIN KLEIN, M D, ROBERT J JOPLIN, M D, JOHN A REIDY, M D, JOSEPH HANELIN, M D, Massachusetts General Hospital, Boston Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1953 Pp 130 49*s*

THIS short monograph is one of the American Lectures in Roentgen Diagnosis series and naturally emphasises early diagnosis of the condition The text is brief and clear, following, in the main, the same lines as most orthopædic teaching in Great Britain It offers no new ideas, and has nothing to say about ætiology, but it lays down clear criteria on which the diagnosis should be made The radiographs are outstandingly good, most are reproduced without any reduction, and there is a splendid series of films showing the normal male and female hip from the age of a week to 17 years

In the section on treatment the authors recommend early weight bearing after fixation, even in cases needing open reduction This they reserve for cases with a slip of more than 1 cm, and of such duration that closed reduction is impossible, a Smith Petersen nail is used in all cases, and they recommend its later removal, to avoid the not uncommon complication of fracture of the femoral shaft at the site of the pin head They illustrate several cases where growth has continued for several years after pinning, so that the pin was left behind and no longer penetrated the epiphyseal plate They apparently find no need for any wedge resection of the metaphysis of the neck, as used by Foley in this country to get rid of the new formed bone, nor do they mention the possible danger of stretching the posterior capsular vessels over the "beak" at the back of the neck if reduction is done without this precaution Nevertheless, in their series of 81 cases, they do not seem to have had any examples of aseptic necrosis of the femoral head Suitable warnings are given about the danger of the contralateral hip slipping, even when the patient is laid up in bed

This little book will be welcome to both radiologists and orthopædic surgeons

Treasury of Human Inheritance

Vol 5 Part 2 *On Syndactyly and its Association with Polydactyly* JULIA BELL M A, F R C P London Cambridge University Press 1953 Pp 50 10*s* 6*d*

DR Bell has once again done a valuable service to students of human heredity by collecting and analysing all the published pedigrees of one group of abnormalities The deformity here considered is essentially syndactyly Polydactyly is included only where it is associated with syndactyly and syndactyly is the predominant deformity Pedigrees where polydactyly is the outstanding deformity are to be considered in another volume

There are many varieties of syndactyly (the great maj of them occur sporadically) Dr Bell has, however, been a to separate the 63 published pedigrees into two main gro leaving a relatively small unclassifiable residue The lar group are those in which there is webbing of the second third toes with no abnormality of the hands The ot common group is characterised by webbing of the ring middle fingers It is not unusual for the fourth finger to b part reduplicated and this reduplication is included in web It is rare to find webbing of the hands associated w webbing of the second and third toes (that is to say, a c tion of the features of the two main groups), but many of individuals with webbing of the ring and middle fingers webbing of the fourth and fifth toes, often with a reduplica little toe included in the web

There is one apparent instance of inheritance deter by the gene on the Y chromosome here there was bil webbing in 14 males in four generations and every son of affected male was also affected

LONDON SATURDAY, NOV 14 1953

Hypothermia

In the past few years the deliberate induction of hypothermia has come to the fore as a means of lessening certain operative and anæsthetic risks Reduction of body temperature, and therefore of metabolism cuts down the oxygen needs of highly specialised organs such as the brain and heart to the level of less important tissues and the blood-supply to these organs can then be temporarily interrupted or diminished There are, however, dangers in hypothermic states and a considerable amount of experimental work has been carried out in attempts to assess the various factors concerned

In this issue Dr Churchill-Davidson and his colleagues describe experiments on surface cooling by immersion in iced water designed to assess the dangers of this technique Their results in dogs, which do not differ greatly from those previously reported, suggest that surface cooling is a simple and safe method of reducing the body temperature, provided this is not allowed to fall below 26°C Clinically, this method is likely to be restricted to children while cooling of the blood stream by means of the extracorporeal circulation, as described by Delorme[1] may be preferable for adults. Special blankets through which ice cold water is circulated in pipes and on which the patient lies, is an alternative With this method skin necrosis may very occasionally ensue owing to the uneven pressure of the dependent parts of the body on the blanket, but this slight risk has to be set against the physiological disadvantages of the extracorporeal circulation with the associated need to insert a cannula into a large artery and vein All these methods produce an effect only slowly—upwards of four hours may be needed to bring a normal sized adult to a temperature of 26°C—and cooling of the peritoneal or the pleural cavity which is mentioned by Churchill-Davidson and his colleagues, certainly warrants further trial These investigators have clearly shown the dangers, first of ventricular fibrillation at temperatures below 26°C, and secondly of unexplained fatal pulmonary complications after rewarming Cardiac arrhythmias are usual below 5°C, and occasionally ventricular fibrillation develops which is irreversible at temperatures below 22°C This work has been done on normal dogs in which the margin of safety was found to decrease with increasing age The most obvious clinical application of hypothermia is in the operative treatment of congenital heart-disease in children but though young these patients have far from normal hearts, and the complications of cooling might easily arise at higher temperatures than those found experimentally to be safe Further experimental work will no doubt be directed to averting these dangerous complications, since there is little doubt that hypothermia is of practical value One reason why it has been developed is in order to work safely in a dry heart, and this ideal will not be achieved solely with hypothermia, except for brief periods unless very low temperatures can be obtained

In the light of our present knowledge there is little or no justification for using this technique for surgical operations which can be properly done without its aid In cardiac surgery the clearest occasions for its use seem to be for operations on the great vessels which cannot be completed without temporarily stopping the blood supply to a vital organ such as the brain, and for operations to repair septal defects in the heart Lewis and Taufic[2] have already reported the closure of an atrial defect with the aid of hypothermia in a girl aged 5 years who recovered fully and other workers have had similar successes but the dangers of the operation are considerable Unless the cardiac outflow is occluded low enough to include the origin of the coronary arteries, air may enter these during the opening of the heart, and even if this is avoided ventricular fibrillation is always likely

Hypothermia has been used clinically as an ancillary to the surgical treatment of the tetrad of Fallot by the Blalock Taussig operation This would as yet hardly seem an acceptable indication the operation has been done without hypothermia in many thousands of cases with so low an immediate mortality as to suggest that in most cases reduction of body temperature may enhance rather than decrease the risk Moreover the fall of pressure in the right ventricle that accompanies the general fall of blood pressure when the body is cooled may prove disadvantageous—and even dangerous—in the presence of obstruction at the pulmonary valve In very severe cases, where a high operative mortality is to be expected, there may be some justification for cooling, but the wish to assess the practical value of this new method should not obscure the possibility that there is no real need for it Hypothermia may prove useful in neurosurgery and in a limited form, in cases needing anæsthesia with controlled hypotension since some of the hazards of hypotension could be diminished by decreasing the oxygen needs A moderate reduction of temperature may become a valuable adjunct to the use of the artificial heart It may also be of value in the treatment of shock, and in toxic illnesses in which fever is prominent and the normal defensive mechanism of the body inadequate

In some Continental clinics various agents are given before during and after operation to lower metabolism by producing a state of artificial hibernation[3,4] and French work in this connection is reviewed by a correspondent on a later page Hypothermia is often used as an ancillary to this method—in fact many of the drugs prescribed facilitate cooling by depressing the temperature regulating mechanisms—though irrespective of deliberate cooling the body temperature will fall a degree or so Much of the success of the technique apparently depends on chlorpromazine hydrochloride ('Largactil'), which has been developed from compounds of the anti-histamine group, though it is almost devoid itself of anti histamine activity This drug is said to depress various parts of the autonomic and central nervous systems, and also the endocrine system The patient will gain great advantage if it proves possible to depress differentially the body-readjustments that follow the trauma of surgery and anæsthesia, so that harmful processes are retarded and reparative ones allowed to progress

Many problems concerning hypothermia are still unsolved, and meanwhile its clinical application should be confined to patients whom it is clearly likely to benefit

Subclinical Poliomyelitis Infections

EPIDEMIOLOGISTS concerned with the prevention of poliomyelitis need to know how many silent subclinical cases accompany each overt paralytic infection Estimates, based on indirect methods, have varied from 100 to 1000 subclinical infections to each paralytic case Thus, MELNICK [1] measured the amount of virus excreted into New York sewage at a time when the incidence of poliomyelitis was low, and he concluded that there were about 1000 silent excretors of virus to each paralytic case COLLINS [2] found that only about 1% of young adults aged 20–24 gave a history of paralytic poliomyelitis, and since the attack-rates are negligible above this age he concluded that adult immunity had been gained at a cost of 1 paralytic illness to about 100 abortive infections HOWE [3] compared attack-rates of measles and poliomyelitis, and by reasoning similar to that of COLLINS he concluded that there were about 200 subclinical infections to each paralytic case Many epidemiologists, however, regard these figures as excessive Thus, BRADLEY [4] speaks of "the probability that the infection moves through a relatively narrow stream of the population", and AGERHOLM,[5] taking up this idea, suggests that damming the stream might halt the flow of the disease and should not prove too difficult administratively

MELNICK and LEDINKO [6] have now found strong evidence against the hypothesis of a narrow stream of infection. These workers used the new tissue-culture techniques for studying neutralising antibodies to the poliomyelitis viruses They investigated samples of serum from 200 children in Winston-Salem, North Carolina, who were bled in 1948, first just before a poliomyelitis epidemic and again six months afterwards Tests of the pre epidemic sera revealed a very low previous incidence of infection with any of the three types of poliomyelitis virus in children under 4 years of age, but a higher proportion of older children showed antibodies—a finding which correlated well with the fact that the last outbreak of poliomyelitis before that of 1948 was in 1944 Sera taken after the 1948 epidemic showed that quite a high proportion of children had developed antibody to poliomyelitis viruses of types 1 and 2 during the summer, no evidence was found of infection with type-3 virus MELNICK and LEDINKO calculated the proportions of children in different age groups infected during the epidemic They infection-rates were then compared with the known paralysis-rates in the epidemic, and it was found that the number of subclinical infections per paralytic case was 175 for infants under 1 year of age, 100 for children aged 1–2 years, 73 for children aged 3–4 years, 62 for children aged 5–9 years, and 95 for children aged 10–14 years It was also found that previous infection with virus of type 2 or 3 did not prevent infection with type-1 virus in 1948 MELNICK and LEDINKO did not investigate whether adults were undergoing subclinical infections during the epidemic, and this may be an additional source of spread.

These findings suggest that poliomyelitis cannot be accurately pictured as moving in narrow streams through the community, and that the major part of the flow is through wide, subterranean channels Quarantine restrictions against poliomyelitis have been likened to closing the stable door after the horse has bolted They are better compared to mending a leaking bottle after most of its noxious contents have already escaped, the attempt to prevent the last few drops from escaping, however desirable, should be viewed in the light of the damage already done This new evidence will discourage the adoption of stricter quarantine measures The main hope at present is from vaccines[7], but because of the large number of subclinical infections and the low paralytic rates, it may prove difficult to assess their protective power The aim will be to produce either a live attenuated virus vaccine which will confer lifelong immunity, or else a killed virus vaccine which will convert the paralytic cases into silent subclinical infections

Diarrhœa after Gastrectomy

A NOT uncommon consequence of gastrectomy is looseness of the bowels, sometimes amounting to diarrhœa, starting two or three days after the operation Though usually transient this may last for weeks or even months It has usually been attributed to the greatly diminished secretion of hydrochloric acid in the days immediately after the operation, and the neutralisation of any acid present by the pancreatic and intestinal juices which now have free access to the cavity of the stomach remnant Ingested bacteria, no longer destroyed by the acid, pass into the jejunum where they find conditions eminently suitable for propagation The upper part of the small intestine reacts by becoming inflamed and pouring out large quantities of exudate How exactly accommodation to the strange new state of affairs takes place we do not know On an earlier page Dr WILLIAMS and Mr PULLAN describe the illness of the patients in whom the diarrhœa was so severe as to cause death in five and to threaten life in the remainder Fortunately the condition can rarely be as serious as this, for they could find only these ten cases in all the St Thomas's Hospital records The patients present a characteristic picture The operation proceeds as usual, and for forty-eight hours all s to be well Then diarrhœa sets in, and with it com latory collapse so great that within two or three da the patient may die The pulse is rapid and threa

7 See *Lancet*, 1953, i, 777

d the blood pressure is too low to record, the nperature is usually raised There are no signs of :itonitis, but there are cyanosis, a pinched face d dyspnœa The intensity of the collapse seems to related to the enormous amount of liquid lost by the wel If the patient dies, necropsy shows extensive crosis of the mucosa *of the small intestine a large* bular slough may form Microscopically there is tle cellular infiltration, and the submucosa is intact, if the patient recovers regeneration can take place om the deeper parts of the glands No abnormality n be seen in radiographs subsequently taken after a rium meal The stomach shows no abnormal anges, and repair at the suture lines appears to be ing on satisfactorily Recovery is quite rapid if ergetic measures are taken These consist in the fusion of glucose saline solution in large quantities—metimes as much as three litres an hour during the utest stages It seems also essential to replace otein loss by plasma or whole blood

The cause of this serious complication is not clear *o significant alteration in the intestinal flora could be* und by WILLIAMS and PULLAN *Clostridium welchii* not mentioned as being present, though it must be esumed that anaerobic cultures were made Some ght may be thrown on this problem by the observa ons made by Professor HOWIE and his colleagues lso in this issue), who found *Cl welchii* in the pirated gastric contents in twelve of fifteen patients bmitted to gastrectomy of whom only one had a tle diarrhœa The presence of toxin in the aspirated quid suggests that the *Cl welchii* were not just in ansit but were living in the stomach. The patients rum was found to contain only negligible amounts of ititoxin but no great importance should be attached this observation since the serum of a woman with *ere Cl welchii* postpartum *infection contained only* ry small amounts The suggestion is that the wering of the acidity in the stomach after gastrec my allows the organism to survive within it, and e alkaline anaerobic conditions of the jejunum are ry favourable to its growth. The absence of flammatory reaction in the deeper part of the wall the intestine gainsays invasion of this by the ganism The diarrhœa could be ultimately a emical irritation due to the toxin amounting to rosion of the superficial layer of the bowel wall

W WILLIAMS in 1927 pointed out, in an important iper on the toxæmia of intestinal obstruction[1] that *welchii* could not flourish in the small intestine cause of the rapid passage of food through it and e acid in the large intestine was apt to kill it off so at on culture of the fæces, it could not be demons ated Yet it seems almost inconceivable that with e intense diarrhœa of the very severe cases now ported by WILLIAMS and PULLAN there should be evidence of its presence in the fæces

In another paper this week Mr RUTTER records a se in which necrosis of the gastric remnant developed ter subtotal gastrectomy *Bacteriological findings* e not recorded, but it seems possible that infection th *Cl. welchii* contributed to the patient s death. he next step will be to find out whether antitoxin effective in such cases as are reported in these three ticles or is even indicated as a prophylactic before peration

THE ASCENT OF EVEREST

A THRILL enhanced by its happy coincidence with the Coronation must have been felt by most people in Britain when the news resounded through the rain-swept and crowded streets on June 2 that Everest had at last been climbed Men and women who had never before admitted an interest in mountain climbing felt that something symbolic had happened.

Since the first attempt in 1921 doctors have played their part in many ways upon the mountain. But, like Dr Michael Ward in 1953 they have mostly gone as climbers or at any rate as experienced mountain travellers, with their medical responsibilities added to their primary duty of getting up the mountain or helping others to get there It is surprising, in the circumstances that they have found the time to bring back so much physiological material and so many new facts about the medical aspects of great altitudes now comfortably enshrined in standard textbooks of physiology The 1953 expedition differed from its predecessors in having with it a physio*logist who was not a mountaineer It would be unkind to* his distinguished predecessors to suggest that he was in consequence the better physiologist but no man can serve two masters when both are hard taskmasters. This time Dr L G Pugh was able to apply his whole mind to the physiological problems of life at great altitudes

The Ascent of Everest,[1] Sir John Hunt s account of the expedition, is published this week It is a remarkable work made the more noteworthy by beautiful photographs in colour the preparation of such a volume in so short a time is no mean feat. Appendices by Dr Pugh and Dr Ward suggest that full use was made of opportunities never before accorded to a professional physiologist The account of the physiological difficulties encountered is admirably clear and whets the appetite for the more detailed and technical reports which is presumably being prepared It is impossible in a book intended for the lay reader to do more than explain the general principles which are already well known to medical readers Pugh and Ward emphasise the importance long realised, of slow acclimatisation from 14 000 feet up to about 23 000 feet and of spending as short a time as possible above this level lest deterioration should set in, adding the new and interesting observation that men going too quickly to even 18 000 *feet suffer not merely from lack of acclimatisation but* from earlier deterioration. Like their predecessors in 1933 they found that tired and overstressed men recovered completely only if sent to lower levels The added work of a fresh ascent later was undertaken in better heart They confirmed too that old timers acclimatise more quickly than greenhorns in the Himalaya

Matters of diet fluid and electrolytes were neglected by pre-war expeditions—such things were not yet in the news. Members of the early expeditions were ill acclimatised and suffered from anorexia The 1933 expedition was well acclimatised and unprepared for the hearty appetites of its members. The expeditions of the later '30s were a little too much addicted to that toughness which as Pugh and Ward say has no place in Himalayan climbing Probably no Himalayan expedition has been as well fed as this one, but even *so there* were times when food ran short. Anorexia was proved to be a symptom of ill health and so of lack of acclimatisation and by inference of bad organisation. Cooking of an adequate diet at great altitudes was greatly improved by the use of pressure-cookers which were so successful that the Sherpas a conservative race went so far as to improvise their own pressure cooker out of old tin cans A low fluid intake has often been suspected of being a part cause of fatigue at great altitudes, where every drop of moisture must be obtained by melting snow—a process laborious and expensive in fuel and therefore in man-power Somehow or other the 1953 expedition managed to ensure an intake of 5–7 pints per man, compared with the single pint consumed by the Swiss in 1952 Since much of the fluid loss is by way of the lungs rather than the skin, loss of salt was a less serious problem and easier to solve

[1] The Ascent of Everest. By Brigadier Sir JOHN HUNT C.B.E., D.S.O London: Hodder & Stoughton. Pp 300 25s

We shall look forward to a more detailed discussion of the oxygen problem That oxygen, given a suitable apparatus for its carriage, would be of inestimable benefit has never been doubted by serious physiologists Whether it is necessary is another and more difficult matter It has never been proved that man cannot reach the summit of Everest without it, and the arguments that he cannot which have lately been put forward (and rather mysteriously accepted without question) have been very specious Five men have reached 28,000 feet without oxygen apparatus, and it is doubtful whether any of them were turned back by oxygen deficiency alone That a ceiling exists is certain, but we are not yet sure that it lies below 29,000 feet This is one of the few puzzles which the 1953 expedition has left unsolved

PLASTIC SURGICAL DRESSINGS

IDEALLY a dressing should be protective against bacteria and abrasion, flexible but tough, transparent, and permeable to water vapour Furthermore it should be innocuous to tissue, it should not interfere with chemotherapeutic agents, and it should not be too costly

Flexible collodion forms a plastic, adhesive, and cheap dressing, but on evaporation of the solvent it contracts, and furthermore it hermetically seals the wound The various adhesive elastic dressings are either impermeable to moisture or irritating to skin, and they are opaque, while adhesive cellulose tape does not allow evaporation of sweat, although it has been used for some purposes—for example, strapping umbilical hernia in infants [1]

Farquhar and Lewis [2] suggested transparent 'Polythene' sheeting strapped over a window in a gauze swab as a dressing for transfusion wounds, so that the incision could be watched for sepsis without exposing it More recently a partially hydrolysed casein gel has been used in the treatment of burns [3] The dressing forms an insoluble protective film of coagulum which is pliable and also semipermeable, permitting evaporation of water, but it is not transparent Polyvinyl plastic [4] is being tested as a dressing which may be sprayed on burns from an aerosol can or pump On evaporation of the solvent, it forms a tough, flexible, adhesive, and transparent film which is permeable to water vapour but not to bacteria Experimental trials have been encouraging, but trials in man have not yet been reported

A plastic surgical dressing ('Bonoplast') described at the conference of Scandinavian surgeons in June has aroused much interest This substance is an acrylic resin dissolved in a mixture of acetic esters, and when spread thinly on the dry skin with a polythene applicator it forms in a matter of minutes a tough, transparent film which is permeable to moisture The film is not injurious to tissue, and experimentally superficial wounds have healed more cleanly than in a control series where conventional gauze dressings were used The solution is self sterilising, and the resultant film impervious to bacteria, surgeons have used it for preparing the operation field, making the incision through the dry film and then painting over the operative wound after sutures and clips are in position. The film eventually flakes at the margins and can be stripped from the removal being aided by spirit or benzene Disadvant are few One is that the film will not adhere to a surface The solvent is inflammable, but the dried is not and may be cut with the diathermy knife solvent gives rise to temporary stinging in unanæsthetis tissue, and there is a tendency for bleeding to be local prolonged, but this may be minimised by good stasis and suturing The dressing has much to it for certain fields—for example, herniotomies in —where the wound requires protection from local Because the dressing is pliable it may be used in region of joints, and it has also proved satisfactor facial work It seems not to antagonise the at the point of contact, and it has been suggested an antibiotic might be incorporated in it Finally, these days of rising costs, it is of particular interest Swedish hospitals carrying out trials have found a saving in the cost of surgical dressings—not to speak the very considerable economy in the nursing-time The preparation of an aerosol means expense, but the simple applicator gives perfe satisfactory results Further trials are taking place in Sweden and in the United Kingdom

ALCOHOLISM IN FRANCE

ACCORDING to a W H O report,[1] France in 1945 1420 alcoholics with complications per 100,000 (a prevalence exceeded only in Switzerland with and Chile with 1497), while the total number of F alcoholics, with and without complications, per 100 adults was 2850, which was exceeded only in the U.S. with 3952

Rouvillois and Dérobert [2] find that in the century there have been five well defined phases

1900 to 1914 —Alcoholism was rife, and the evils of a contributed to its steady rise without any legislative re

1914 to 1918 —Owing to the war, anti liquor laws passed The manufacture and sale of absinthe was pro in 1915, the number of licensed premises was reduced in and drunkenness was suppressed in 1917—which re in a decrease in alcoholism to a level lower than had obtained

1919 to 1939 —Legislation favouring the productio alcoholic drink was introduced as a result of pressure vested interests of the liquor trade the war time laws revoked and various new laws were introduced, such as of 1922 allowing the manufacture of alcoholic drinks with aniseed base, replacing the former absinthe, various permitting the re opening of licensed premises closed the war and the opening of new ones, and a law in giving exchequer aid to the advertisement of alcoholic During this phase alcoholism increased again, and by outbreak of the second world war had reached a higher than ever before

1939 to 1945 —Alcoholism increased by leaps and during the period of mobilisation, the "phoney" war, German invasion, but diminished during the years of occ tion, with its hardships and scarcities and repressive legislation At the time of the Liberation, alcoholism almost be said to be non-existent in France

1945 to 1952 —The experience of the two wars had impression on the legislature which, under pressure the liquor trade, repealed the restrictive anti liquor laws of Vichy régime and passed laws favouring expansion of trade Thus a law passed in January, 1950, perm the advertisement of liquor, another in March, 1951, allo the opening of licensed premises on aerodromes, and laws in the same year re-established the unrestricted manu ture and sale of alcoholic apéritifs, and the rebuilding licensed premises

Rouvillois and Dérobert base estimates of alcohol on three sets of figures deaths from cirrhosis of liver, deaths from delirium tremens, and admissions mental hospitals of patients with alcoholic psyc ho fluctuations in alcoholism as shown by these three gures agree closely with the trends of legislative control. eaths from delirium tremens per 100 000 population ere just under 3 in 1935 fell to less than 1 in 1944 nd from 1946 rose steadily to just over 6 in 1951 eaths from cirrhosis of the liver fell from about 16 per 00 000 in 1935 to about 7 in the war years, then rose harply to about 19 in 1951 Admissions to mental stitutions for alcoholic psychoses amounted to 8 per 00 000 in 1935–39, then fell to under 2 during the war, nd thereafter rose steeply to over 18 in 1951

Rouvillois and Dérobert suggest that the continuing harp rise in all these figures is due to the laxity of the ws, and that the increase of alcoholism in France emands the urgent attention of the government. hey publish maps of the country showing the two ortality figures in various regions in 1946 and 1951 rom these it can be seen how the face of the land is being verspread by this dark shadow

MYXOMATOSIS AT LARGE

IN the autumn of 1952 the myxoma virus escaped om a private walled estate in the French department f Eure-et-Loir where it had been deliberately planted, nd within a year it had spread among the wild rabbits 29 departments [1] Today every department is affected, lthough to a varying extent thus, the animals round aris and Marseilles have suffered much more severely han those in the south west of the country The pidemic is now spreading through Belgium Holland nd Germany where hundreds of millions of rabbits ave already died; and last month the disease was dentified in Kent and Sussex. The incubation period f this horrible infection may be as long as ten or twelve ays before the onset of blepharitis, which is followed y the more severe lesions on the ears and head, the kin and the anogenital region Not every animal hows the typical features, and the French report that hey have seen infected rabbits with very few obvious gns. Terminal pasteurella infections are common and ay confuse investigation. In France this epidemic has aused bitter public feeling not only because of its ffect on a national sport but because there is less meat or the poor, and fewer pelts, both from wild and tame abbits, for the important fur trade

Now that the virus has crossed the Channel we must e prepared for it to spread rapidly but there are few pidemiological data [2] on which to base predictions ustralian workers have shown that several species of osquito can transmit the virus mechanically and this robably explains widely scattered outbreaks. Brereton's elief [3] in a steady creeping advance of the epidemic, t the rate of some three miles a day suggests a more ntimate method of spread. So far there have been no eports from the French biologists who are investigating he disease in the field Jacotot and his colleagues [4] at he Pasteur Institute have found that when uninfected nd infected animals are kept in the same cage trans mission does not necessarily follow On the other hand ven when infection was introduced by pricking the skin ith a contaminated needle only 3 out of 250 laboratory nimals showed a natural resistance to the virus. It lso seems that when a fresh stock of rabbits is introduced nto an area previously cleared by the virus they are nable to withstand the disease for more than a few eeks Probably both methods of spread are important nd if the virus behaves like other members of the ox group various contaminated materials will transmit he infection If this is so then it is unlikely that easures now being taken in Kent and Sussex can do ore than contain the infection for a short time

Before they released the virus the Australians showed conclusively that it attacked only the European rabbit or its more elegant tame descendants, and that it was quite incapable of infecting other closely related species. The hare in particular was thought to be naturally immune but Jacotot and his colleagues [5] have proved that at least one true hare has died of the disease There are two types of hare in France: one is really a rabbit in disguise and may be fully susceptible; and the other is the more usual brown hare The hare examined by Jacotot had the typical lesions of the disease and ticks (*Ixodes ricinus*) recovered from its skin, were capable of infecting rabbits. Attempts to transmit the disease to two other hares were unsuccessful and the conclusion is that infection among hares is probably rare. Apart from the possibility that the red squirrel may be susceptible no other species has so far been infected and the alleged human infections have not been confirmed by laboratory tests It seems that the calculated risk first taken by the Australian workers, who judged the myxoma virus to be stable has so far been justified although no one can be certain that the immunity of other species will last.

UNITS

THE expert committee on biological standards of the World Health Organisation have announced [6] the second international standard for penicillin This step has been necessary because the stocks of the first standard have been exhausted. The new international unit is defined as the activity contained in 0 0005988 mg of the second international standard for penicillin The occasion has been taken by Miles and Perry [7] to discuss what is meant by a unit of a biologically active substance, and on what principles the unit should be determined. The clinician who prescribes such drugs as insulin, heparin calciferol and corticotrophin (A C T H) in terms of units may come to think of these doses as directly representing the therapeutic efficacy of these drugs in man This is not the case: and for important reasons The unit if it is to have meaning must be as nearly as possible an accurately reproducible quantity So complex are the actions of a biologically active substance in the human body, and so many variables may modify the response that assay in man could not allow a unit of constant value to be accurately defined Assay must therefore be made in terms of a definite and measurable activity of the substance in a controlled biological system For example, corticotrophin is assayed by its ability to reduce the ascorbic-acid content of the adrenal gland of the rat after intravenous injection In man this property may not directly represent a desired therapeutic effect of the drug and the physician must learn by experience what effect he is likely to obtain from a given dose in units

This argument is not purely formal but has important practical bearings A substance may possess properties not measured by the current method of assay which nevertheless profoundly modify its action in man Thus, a new preparation of corticotrophin was shown to be of equal potency with the older preparation when assayed by intravenous injection in the rat The same substance was found however to have four times the therapeutic efficacy of the previous preparation after intramuscular injection in man The two preparations were equipotent by intravenous injection in man and the difference between them was presumably related to absorption How is the information about the different properties of the two preparations to be logically conveyed? The method of assay in the rat could be changed to use the intramuscular route But this complicates the biological system in which the assay is carried out, introducing factors difficult to control and thus endangering the reproducibility of the unit. The unit of the new product could be quadrupled, but this would create as many problems as it solved. Since the product cannot be assayed in man, it is assumed that the ratio of intramuscular to intravenous efficacy is the same for the test animal as it is for man—an assumption which at present lacks proof. Another possibility would be to introduce a second unit, but this hardly seems justified for a substance which differs so far as is known only in one property—namely, intramuscular efficacy—from the older corticotrophin. The temporary solution suggested by Miles and Perry is to describe the new product as "corticotrophin H I M"—meaning "high intramuscular activity"—and leave it to the clinician to familiarise himself with the significance of these initials.

[7] Miles A. A., Perry W L M *Ibid*, p 1.

Miles and Perry discuss similar difficulties arising from the proposal to establish an international unit for adsorbed diphtheria toxoid. This should be defined in terms of its content of plain toxoid, which in turn depends on the content of *Lf* units. The addition of, for example, aluminium greatly enhances the immunising power of the product in man without altering its content of toxoid. One unit of the adsorbed toxoid might then have the same immunising power, and thus the same significance to the clinician, as 100 units of the plain toxoid. Therapeutic efficacy is clearly not the same as potency; nor is it an acceptable basis for defining the unit. The unit is a statement of the amount of active principle present in a drug, as determined by an assay of its activity in a controlled biological system. This definition of the unit is essential to its fundamental property—exact reproducibility. Miles and Perry emphasise that it falls to the clinician to determine how a unit thus defined is related to therapeutic effect. He may sometimes be tempted to look upon the standardiser of biological preparations as his handmaiden, and this emphatic statement of principles may perhaps disturb him. But a servant with firm principles is often a very good one, and the views of Miles and Perry are in keeping with the best interests of all who use drugs that have to be standardised in this way.

THE HUMAN FEMALE

THE much-publicised second volume of Dr Kinsey's monumental research on human sexual behaviour is now available in this country.[1] The new book, a worthy successor to its predecessor,[2] is a serious, well conceived, and courageous attempt to provide factual information about a branch of social psychology in which legend and emotion still predominate over knowledge and sense. It should be particularly welcome to doctors even if they feel uncomfortable that it has been left to a comparative zoologist to open up this field. The inspiration belongs to the school of Lorenz and Tinbergen rather than that of Charcot or Freud. It is to the general public, however, that Dr Kinsey's work is really directed—it is the ordinary citizen who suffers most from the ignorance or fanaticism of his sexual mentors, who has to make up his mind on issues of personal morality, and who today is demanding factual information on which to base his judgments. In upholding his right to have such information, the authors of this book stand explicitly in a tradition of American liberalism which cannot fail to be reinforced by their example. The opening chapters, in which they defend that proposition against the irrational and the coercive attitudes in modern society, is a remarkably dignified contribution to that tradition.

The statistical material is based on 5940 case histories obtained by methods similar to those in the previous survey. The interpretation of data so obtained is inherently difficult, since the need to secure full cooperation from the subjects prevents conventional probability sampling, and instead the subjects were obtained by securing the cooperation of groups (detailed in the text) and interviewing, whenever possible, all the members. The recurrent press criticism that the subjects are abnormal and exhibitionistic volunteers is probably unfounded in fact, but the limitations of the sampling method require to be borne constantly in mind, and a more restricted general title for the book might have served to underline these, and the authors' awareness of them. Reference to "the human female" would not have pleased Karl Pearson, despite the authors' explicit disclaimers.

The statistical material on frequency and character of "sexual outlet" is if anything rather better presented than in the earlier study, and is a good deal easier to assimilate. A definition of sexual outlet in terms of orgasm alone may offend the Freudians, but there is much to be said for it in a study where some arbitrary form of categorisation is essential, and it is refreshing to see a work of social anthropology in which the word "sex" is permitted to retain some over all connection with specifically reproductive behaviour. The data concerning prevalence of various forms of sexual activity contain little which will be new to any working social psychologist, though they may surprise others. Perhaps the least expected findings were the high incidence (26%) of extramarital relations in married women, and of orgasm following erotic dreams (40%), a subject on which little previous work has been done. As in the previous book, Dr Kinsey presents much material which will lead to serious rethinking of our attitudes to childhood and adolescent sexuality. More important than the statistical material, from many points of view, is the careful review of the physiology of sexual stimulation and of orgasm. No other important physiological process has been so little studied. Quite disproportionate harm and unhappiness is often caused by inadequate sex relations. The expulsion of the legendary and the anecdotal can be very simply achieved by providing an occasion for comparing notes, and this is an important undertaking in itself.

The whole study, though exhaustive and occasionally exhausting, has the very high merits of humanity and a good deal of dry humour. Dr Kinsey's team has already deserved very well of public opinion, but its most important work is yet to come, in the impending study of the attitude of the Law and the penal system toward sexuality, which is promised as the next in the series. This attitude is widely regarded, and not only by "armchair reformers," as one of the least civilised and most discreditable aspects of modern Western societies. Dr Kinsey has already shown that if the laws restricting sexual conduct could be fully enforced in the United States, 95% of the male population would be in prison. The consequences of prosecuting homosexual offenders, especially when such cases follow a wave of ill informed public emotion, such as appears to be threatening here at present, are far more serious, and fall on a far greater number of victims, than the consequences of the behaviour which is being so savagely punished by society. It requires little imagination to see that a penal system can be based on the assumption that sexual activity can be indefinitely suspended in healthy adults is at variance with reality. The study of sexual behaviour makes it increasingly difficult to shelve or ignore such problems as these. We are becoming aware that many traditional attitudes are often painfully akin, themselves, to psychopathology, and that the inspiration behind much sexual legislation does not come from the best adjusted or most reasonable section of the community. "Somehow," writes Kinsey in his preface, "in an age which calls itself scientific and Christian, we should be able to discover more intelligent ways of protecting social interests without doing such irreparable damage to so many individuals nd to the total social organisation to which they belong the work of the Indiana University team has no other sult it will have achieved a major philanthropic purpose emphasising this fact alone

NIGHT SHIFTS

INCREASED production is continually being demanded British industry and the question of night shifts, make the best use of personnel and of factory space nd equipment, demands the closest attention Wyatt nd Marriott,[1] of the Medical Research Council group for search in industrial psychology throw some light n the factors affecting the morale and efficiency of orkers on night shifts and on the relative effects of eekly fortnightly and monthly alternations between ay and night shift work.

Data collected in 1946–49 in three factories (A making ilway wagon wheels B a rolling mill and C making otor vehicles) all employing men and having respec vely weekly fortnightly and monthly changes from ay to night shift were closely studied and a number of en from each factory were interviewed to ascertain heir attitudes. Output records from two of these ctories together with those from eight others—making total of three on weekly shift-changes four on fortightly changes and three on monthly changes—howed that the average hourly output was slightly ss on night work Wyatt and Marriott point out owever that the night worker being paid at a higher ate may reduce his output in order to keep to his esired wage level without undue exertion Of 150 en questioned about their opinions of their efficiency n day and night work 68% claimed to work better by ay 21% reported no difference and 11% thought they orked better by night The attitude of the individual as related to the effects of shift changes upon his sleep nd eating habits.

In the four factories with fortnightly alternations f shifts, comparison of the average hourly output in he first and second week of day shifts showed that it as slightly higher in the second week—which suggests hat the effect of two weeks on night shifts carries ver to the beginning of the following day-shift period. In ten factories engaged on various types of engineering nd using the fortnightly alternation of shifts the bsentee rate was higher on the day-shift period (8 89% f possible shifts, as compared with 7 00%) These igures however included permanent day workers who might be unfit for night work Other complicating factors are the greater counter attractions outside the factory for the day worker and the high rate of absence on Saturday mornings. Accident-rates of 13 962 men in five factories were slightly higher for night work, but the difference was not statistically significant.

Wyatt and Marriott remark that opinions expressed by the workers are likely to reveal important and unsuspected aspects of the situation that are not disclosed by objective records. A sample of 150 men from factories A B and C were carefully interviewed. Almost all the men preferred the day shift—41% because it gave them the evenings free About a third said they felt better on day shift especially as regards sleep 20% said they had a better appetite and digested their food more easily; 34% disliked night shifts because they could not get enough sleep by day When asked whether they would opt for a weekly fortnightly or monthly alternation of day and night shifts a majority in each factory opted for the existing system—an example of the general tendency of workers to prefer what they are accustomed to Questioned about fatigue 83 3% said that they felt more tired on night shift and only 8 7% on days the remaining 8% noticed no difference Almost all the men brought sandwiches to work; 70% preferred to bring their own meals rather than eat the canteen food 74% said they enjoyed their food better when on day shift. 65 of the 150 took patent medicines regularly mostly for stomach disorders, and 33% also took aspirin fairly often 24 men had occasional indigestion and 7 more had continuous indigestion Wyatt and Marriott suggest that quite apart from the irregular meal times, the diet of most of the men was unbalanced; it seemed that they received no guidance on the subject either in the factory or outside In the matter of sleep 83% adapted themselves immediately on changing from night to day shift but only 50% in the reverse direction. 42% said they could not get enough sleep by day 37% had less than six hours sleep by day while 75% had less than eight hours

Wyatt and Marriott conclude that far more attention should be given to the selection of workers for night shift and to the medical supervision of those selected They suggest that the fortnightly alternation of day and night work is probably the best.

TESTS OF SPERMICIDAL ACTIVITY

CONTRACEPTIVE pastes and jellies designed to be used with or without a rubber appliance, should combine rapid spermicidal action with a mechanical barrier effect But by giving a compound greater viscosity one may prevent the escape of the active spermicide into the semen Thus in studying the efficacy of a contraceptive product we need to measure not only its total spermicidal power but also the speed and completeness with which the spermicide will get out of the base and attack the spermatozoa. For this purpose J R Baker devised the diffusion test but it has technical disadvantages Davidson[1] has therefore proposed a modification, which he calls the contact test, in which spermicide and semen are brought into contact on a special slide, without mixing or mechanical disturbance Another test with the same object, had previously been described by Gamble.[2]

In Davidson s test a layer of semen 1 mm thick lies on a similar layer of contraceptive in a sealed cell 5 mm. in diameter through the roof of which the spermatozoa can be observed Gamble s test is carried out in a piece of glass tubing 20 mm. long with a lumen 2 mm in diameter The tube contains a column of air 5 mm long a column of semen 5 mm. long and a column of the paste or jelly to be tested 10 mm long The ends are sealed with wax and the tube laid horizontally on a glass slide The surfaces of the jelly and semen are in close contact.

The principle of the two tests is the same and both have the merit of using very little semen (Davidson 18 8 c mm Gamble 15 7 c mm) which allows several tests to be made with one ejaculate The difference lies in the area of contact between the semen and the contraceptive. In Davidson's test this is 18 8 sq mm while in Gamble s it is a little more than 3 sq mm It is generally accepted that there is almost no movement of molecules through the matrix of the jelly and that only the surface layer will yield spermicide to the semen so the maximum concentration of spermicide from a given contraceptive should be more than five times greater in Davidson s test than in Gamble s. Moreover in Davidson s slide none of the spermatozoa are more than 1 mm from the surface of contact whereas in Gamble's tube the spermicide must be distributed through the 5 mm column of semen before all the sperm are affected by it Gamble attributes the streaming in the semen which ultimately leads to the death of all the spermatozoa, to convection currents set up by changes in density of the semen as it dissolves the spermicide, in which case the rate of mixing would be proportional to the rate of solution but streaming may also be produced by changes of temperature, and their effect on the air in the tube. With Davidson's test, satisfactory substances kill all spermatozoa in half an hour. Gamble's test naturally takes much longer but this carries some advantages. The viability of human semen deteriorates quickly, and the resistance of spermatozoa to toxic chemicals, especially at body-temperature, falls with delay; so the value of tests taking over three hours is rather questionable. Within this time, however, the rate of immobilisation of the spermatozoa is more gradual; and it is possible to compare the rates at which contraceptives act, and (provided the results for each substance are consistent) to arrange them in order of relative efficiency. Unfortunately Gamble's figures indicate great variation in tests with a single product: in a series of tests with a standard deviation of 38% of the mean, and an average of two hours for complete immobilisation of the spermatozoa, the individual results could range from half an hour to three and a half hours. This degree of variance is so great that it is difficult to suppose the grading of contraceptives would be more accurate than with Davidson's method. The principal merit of Gamble's method, as we see it, is that, instead of a special slide, glass tubing—which is always available—can be used; though this has the drawback that spermatozoa are hard to see through the side of a cylindrical container.

[1] Davidson H A. *Lancet*, Aug 29 1953 p 439

[2] Gamble C J *J Amer med. Ass.* July 11 1953 p. 1037

Neither test, of course, is intended to reproduce conditions in the vagina; but it is hard to see why Davidson vetoes the use of incompletely liquefied or persistently mucoid semen. Such semen, being exceptionally resistant to the passage of spermicides, would certainly increase the time taken in the test; but contraceptives always have to act on freshly ejaculated semen, and often on mucoid specimens, and it seems reasonable to suggest that every commercial preparation should be tested at least twice against such ejaculates.

ADOPTION AND MENTAL HEALTH

To be deprived of a natural mother and taken over by a substitute, however loving, inevitably exposes a child to emotional risk. The joint United Nations and World Health Organisation meeting of experts on the mental health aspects of adoption, who have just reported,[1] have concentrated on seeing how far this risk may be minimised. To advise the whole world on such a subject is not easy, because customs differ so greatly from East to West: they have therefore concerned themselves chiefly with the principles on which adoption procedures are based in Western society.

They restate at the outset the now well accepted belief that adoption is the most complete means of restoring family life and relationships to the child without a family. The satisfaction of the desire of childless people for children is, they think, of secondary importance. Most children in need of adoption are illegitimate, which means, as a rule, that they can be adopted in infancy. Sometimes, however, a mother who wants to keep her child manages to do so until he is two or three years old, and then finds that the difficulties are too much for her. Separation can then be a bitter experience for both mother and child. The report also mentions the particular situation of brothers and sisters deprived of both parents: they naturally cling together, and it is very doubtful whether it is wise to allow them to be adopted singly, unless groups of adopting parents known to each other will each take one or two of them. This is not easy to arrange, and of course brings its own stresses; but it is perhaps better for the family than an institutional upbringing would be.

Any child who is adopted needs to be able to count on the continuance of loving care. The parents must be able to offer him a whole-hearted acceptance, taking him as he is, giving him not only love but a chance to love back, and letting him blow off, without too much guilt and anxiety, the conflicting and often hostile feelings to which frustrating reality makes us all a prey. In fact he needs normal mothering and a home where he can make normal relationships with a father, other children, relatives, and friends. If he is more than a few months old he should have some chance to get to know his new family before he goes to them, and if he is old enough to notice toys he should take a favourite one with him to his new home. The expert group, however, were dubious of the practice followed by some adoption societies of placing the child with its adopting parents for a trial period—usually three months—before adoption is decided on. This is said to give the real mother time to reconsider the position, and change her mind if she wishes, and also to allow the adopting parents to find out whether they like this particular baby; but it is an arrangement which carries considerable emotional risks for all parties—for the mother because it exposes her to disqueting doubts and fosters her almost inevitable sense of guilt about the transaction, for the adopting parents because they may either become too fond of a baby whom they suddenly abruptly lose, or because they feel their motives are being scrutinised suspiciously, or because warm acceptance of the child as he is may be replaced by a mood of appraisal, and for the child, above all, because it exposes him to a chance of being bandied about from one mother to another. If we accept the needs of the child as paramount it must be agreed that, for him, the trial period has serious drawbacks which are hardly outweighed by the gains.

The group think it important to make sure of the motives of the would be adopters, and their attitude to the child. If they want him because a child of their own has died they first need time to resolve their sense of grief and loss; if they are hoping he will patch up an unhappy marriage, or if he is expected to resolve the neurotic problems of one of the partners, they are putting their own needs first. Single women (except the child's mother) and widows are liable to have mixed, partly selfish, motives, and it is therefore thought better for the child to be adopted by a married couple. The natural mother ought to be given practical information and advice by a trained and well balanced person, so that she can decide freely whether to keep her child or have him adopted; and of course the adopted child should be given legal status which entitles him to the same opportunities and rights as a child in an ordinary family. Adopting parents should not have the right to repudiate the child later if he turns out badly. The group believe that the child should know from an early age that he has been adopted.

Some interesting though tentative suggestions are made about the adoption of handicapped children. There are some people whose warm parental feeling fits them to look after a child with a handicap; and it has been found that adoptions of this kind can turn out well, provided the child's needs and the suitability of the home are carefully studied.

THE Nobel prize for physics has been awarded to Prof FRITS ZERNIKE of the University of Groningen "for his phase-contrast methods, particularly the invention of the phase-contrast microscope."

Reconstruction

CENTRALISATION IN THE HOSPITAL SERVICE*

The Need for a Change of Policy

THE National Health Service Act of 1946 opens with he words

> 'It shall be the duty of the Minister of Health (hereinafter in this Act referred to as the Minister) to promote the establishment in England and Wales of a comprehensive health service designed to secure improvement in the physical and mental health of the people of England and Wales and the prevention diagnosis and treatment of illness and for that purpose to provide or secure the effective provision of services in accordance with the following provisions of the Act

This introduction illustrates not only the extremely wide rope of the health service but also the extremely wide ange of the duties of the Minister himself At the same ime these duties are defined only in very general terms n the Act as are those of the Minister s agents the oards of governors regional hospital boards, and hospital nanagement committees

In outline there is a three-tier system of administration nvisaged for non teaching hospitals

The Minister—Regional Hospital Boards—Hospital Management Committees

ogether with a simple two tiered system for the teaching hospitals :

The Minister—Boards of Governors

The Minister is responsible only to Parliament He is o administer through his agents, the boards who dminister through their agents the management com nittees, Existing side by side with this agency method f administration is the direct legal responsibility of a rincipal which is granted to regional hospital boards, oards of governors, and hospital management com nittees (notwithstanding that they are exercising unctions on behalf of the Minister) While the Minister hay therefore impose his will upon each or any of his gents by regulation or direction these agents have a lirect legal responsibility for their actions

Nevertheless this administrative framework though t embodies the agency principle is so constituted as to llow at the Minister s discretion centralised direction n all matters both large and small by liberal use of the dinister s reserved powers subject only to the require nent that the Minister must lay statutory instruments efore Parliament within a prescribed period It is equally onstituted to allow the administration to be entirely lecentralised, and for virtually all responsibility to be laced in the hands of boards and management com nittees acting as agents for the Minister

Intentions

It could be argued that the Act in itself was conceived n a spirit of mistrust While powers are given, all may e negatived if they are not used as the Minister wishes. nstead of being obliged to make the delegation of uthority and responsibility a real working arrangement he Minister can always fall back upon the escape clause f reserved power However in order to allay this feeling f mistrust, the Minister at the time (Mr Aneurin Bevan) nd his Parliamentary Secretary (Mr C. W Key) were t great pains to explain their intentions

> ' This scheme provides that the Regional Boards with their local Management Committees are to enjoy a high degree of independence and autonomy within their own fields —Mr KEY (*Hansard* vol. **422** no 129 col 208)
>
> Moreover, the Boards, and under them the Hospital Management Committees will have a very considerable amount of financial freedom as far as administration is concerned. At the beginning of each financial year they will prepare their annual estimates. Their budget, of course, will have to secure approval but when once it has been approved it will be for the Board to spend the money, put at their disposal by the Exchequer, as they think best, up to the limit of the sum that has been approved. There will be a wide discretion concerning that global sum, and not, as some critics tell us, central control over the detailed items of financial expenditure. —Mr KEY (*Ibid*, col 209)
>
> The central principle of the Bill under which the House places on the Minister the responsibility for these services inevitably means that he must have agents. Every single instrument must be an agent, because when any instrument ceases to be an agent the contract is broken Having established that principle it is then necessary to provide that the central responsibility which the House *places upon the Minister to provide a service does not result* in that service becoming too highly centralised in its administration That is precisely what the scheme provides. It provides for the establishment of Regional Boards ; it provides for Management Committees and for House Committees. In fact the scheme, right through, provides for measures of decentralisation so that individuals in a locality can have as much influence as possible over the medical and hospital services —Mr BEVAN (*Hansard* vol **426** no 185 col 469)

In this way the Government defended their proposals, arguing that only by giving the Minister these wide discretionary powers could there be provided the flexibility of administration necessary for the development of the new health service, and at the same time emphasised again and again their intention that the *administration of the service should be decentralised* as much as possible

The Government's good intentions were repeated in the early circulars that were issued to hospital authorities from the Ministry

> " Broadly, the effect of this administrative structure is that the function of the Regional Board is to determine in consultation with the Minister and as a fluid and constantly developing process the part which each hospital is to play in the integrated service to deal with wider regional problems, and to oversee the operation of the hospital service of their area ; that of the Management Committee is to administer its hospital or group so that it plays its part in the most effective manner Powers of central control are reserved to the Minister because of his ultimate responsibility to Parliament " (R.M.C 48/1)
>
> In framing the Regulations the Minister s object has been to avoid proscription in detail of the manner in which the various bodies are to perform their functions, and by laying down division of responsibility in broad terms to allow the greatest measure of flexibility and variety in administration. His desire is to rely on ordinary methods of guidance by way of advice on questions of policy and not on a detailed code of rules embodied in regulations, for the purpose of maintaining the necessary degree of unity and homogeneity *in the service It is however essential that there should* be reserved to him (as is reserved by the Act) an ultimate power of laying down the manner in which the various functions are to be performed. The Minister s intention is that these ultimate powers should be exercised as infrequently as possible and that normally the ordinary processes of administration will suffice to ensure that the general policy of the service is observed (R C 48/)

Perhaps the clearest statement of policy of all was that contained in the memorandum submitted by the Ministry to the Select Committee on Estimates in 1950

> It has from the outset been the policy of the Minister to allow a wide *measure of independence in hospital* administration to the hospital authorities subject to necessary

---

* Based on a memorandum prepared for the Hospital Discussion Group by a small working party of hospital administrators. The members of the working party were A. H. BURFOOT B.A A.H.A., M C HARDIE M.A R P K MACMAHON M.A. J W MARSHALL, M.A., and J L. C SCARLETT M.A

financial control from the centre The main instruments of that control are

(a) Submission by each hospital authority of an annual estimate, with a revised estimate in the autumn
(b) Formulation of policy in its major features by the Department, which is communicated to the hospital authorities in circulars and memoranda,
(c) Regular periodical conferences with officers of the Ministry of the Chairmen of the Regional Hospital Boards and of the principal officers of Boards,
(d) National determination of salary and wage scales and conditions of employment, &c ,
(e) Monthly returns from the hospital authorities of their expenditure and income,
(f) Liaison through Regional Officers of the Ministry, who may attend the meetings of the hospital authorities and who receive their circulated papers,
(g) Central purchase by the Department of certain supplies,
(h) Current audit of the accounts of the hospital authorities by officers of the Ministry,
(i) Development of a system of hospital costing "

Had the Ministry adhered more closely to this policy it might well have avoided the present widespread criticism of over-centralisation in the hospital services But neither intention nor policy has been entirely fulfilled

Finance

Centralisation of some kind is as inevitable as it is desirable, and the extent of it envisaged in the early circulars cannot fairly be considered either excessive or oppressive

In subsequent years the financial circulars have generally continued to be basically reasonable, and the Minister's financial policy has usually been as flexible as could be expected under the circumstances, and within the framework dictated by the Parliamentary necessity for an annual vote of funds It is in fact the external circumstances that have been responsible for much of the centralisation that now exists funds for hospital building work have been controlled not so much by the needs of the hospital service as by the necessities of the national capital investment programme, policy on salaries and wages (which account for over 60% of hospital expenditure) has been affected by Cabinet decisions, as at the time of the devaluation crisis in 1949 and of the Chancellor of the Exchequer's statement on the stabilisation of personal incomes, and, since there is practically no theoretical limit to the amount of money that could be spent on the Health Service, the annual allocation of Exchequer funds has been determined by the national economic situation, which has called for great financial stringency.

All these factors have combined to increase the centralisation of financial control, and in addition it must be remembered that in the first two years of the service the cost of the hospital service was grossly underestimated, that there has as yet been no accurate method of assessing hospital costs and comparing the relative efficiency of different hospitals, and that all hospital authorities, from the Ministry downwards, are still in process of learning the facts—and particularly the financial facts—of a national hospital service

It is not surprising, then, that there has been greater centralisation than was originally intended But such centralisation may not always achieve either the greater efficiency or the greater economy which are its objectives While the attainment of these objectives must depend largely on improved hospital accounting and costing, two points are worthy of consideration now

(1) The need to give hospital authorities some incentive to effect economies and savings Real savings can be effected only at the hospital level, and it is there that the incentive is needed possibly by allowing savings on the annual budget to be used for the development of hospital plans or for the purchase of improved equipment, at an earlier date than would otherwise be the case

(2) The development of a modified system of block grants for building maintenance and capital expenditure, and a redefinition of these terms Such expenditure would be much more efficiently planned and carried out on a five year basis

In the financial field, therefore, it appears that the form of centralised control is generally reasonable in the light of all the circumstances It is centralised control in other than financial and related matters that causes much of the present discontent

The problem can be considered at two leve[illegible] isation at the Ministry and centralisation at the regi hospital boards

Centralisation at the Ministry

Much of the evidence on this can be taken from the Ministry of Health memoranda issued since 1948 T circulars go to regional hospital boards, hospital management committees, and boards of governors—so to only one or two of these authorities but generally all three simultaneously Until the end of 1952 the t number of circulars issued was

To regional boards	64
To hospital management committees	537
To boards of governors	38

This works out at approximately one circular every [illegible] days to every single hospital authority in the country

Almost every one of these circulars could be justif as being reasonable in its substance and many are in fact concerned with Whitley Council decisions of [illegible] all hospital authorities must obviously be informed Nevertheless, in spite of their general reasonableness and of the ease of filing and reference to them, the system cannot be regarded as satisfactory The recipient [illegible] smothered by the quantity of circulars, some of which not apply to his particular hospital or group, and are issued in the same form, whether mandatory advisory, important or unimportant The general e[illegible] of this is to decrease the attention paid to circulars the hospital authorities, and at the same time to en a dangerous feeling that everything will be covered a circular sometime or other, and this feeling inevitably diminish the sense of individual initiative responsibility that is an essential prerequisite successful management Furthermore, since these [illegible] lars are generally issued by the Ministry simultane to regional boards and management committees, responsibility of the regional boards becomes correspondingly diminished, and it may be difficult for t to fulfil in a true sense their acknowledged rôle of a[illegible] for the Minister and principal for the management committees

More positive advantages might well result from alternative method of distribution, which would [illegible] properly recognise the agency principle In outline the alternative would involve

1 Mandatory circulars to be issued to all hospital authori only when conveying decisions which affect all and on w no local discretion is permissible, such as decisions on of pay or conditions of employment agreed by the Whitley Councils, decisions on charges for appliances, pay t prescriptions, &c , and decisions arising from national pol on such matters as capital investment or Civil Defence

2 All other circulars conveying general guidance advice to be issued only to regional boards (or to boards governors where appropriate), who should be trusted to their own judgment and discretion on the best method implementing them in their respective regions, in co[illegible] with the hospital management committee concerned

This method would give the regional boards [illegible] responsibility, and would also allow greater scope intelligent discrimination in "putting over" the Minis ter's policies Most important of all, it would mark return to the original idea of the principal agent relationship between the Minister and the hospital authori pon which the whole administrative structure of the ospital service ultimately rests

The structure itself has often been held to blame for e faults of the hospital service but this criticism can ardly be considered valid, because the principles on hich the service was based have not been properly bserved It would therefore be premature to condemn e structure at this early stage of the health service d to advocate its replacement as some critics have one, by a revised local authority type of administration, by the creation of a National Hospital Board ith powers and responsibilities similar to those of the ational Coal Board Such extreme measures cannot justified until the present system has been given a ore thorough trial and the most important thing to at the moment is to put into practice the principles hind the present system

HE CIVIL SERVANT AND THE HOSPITAL ADMINISTRATOR

Administratively, the success or failure of the hospital rvice depends very largely upon the establishment of e highest possible degree of mutual confidence and spect between principal and agent at every level and this vital matter there is a great need for improvement

The first point that needs to be emphasised is the fference between the rôle and methods of the Civil ervant and those of the hospital administrator whether edical or lay The rôle of the Civil Servant in relation the Minister is comparable to that of the administrator his board or committee in that each is an adviser d an executive but in addition the hospital adminis rator is responsible for the day to day management of e hospitals under the control of his board or committee his means that in reaching any decision the adminis rator must give great weight to the human factors volved, taking into account his confidence in the staff ncerned and his assessment of their abilities and his ethods will naturally differ from those of the Civil ervant, who is concerned with the comparatively personal problems of the planning and development a nation wide health service rather than with the mediate practical problems of management

In view of this difference of function between Ministry d hospital authorities a difference of administrative ethods is both natural and desirable and given a reason ble measure of respect and understanding on either side hould not lead to difficulty or antagonism What ppears to cause both difficulty and antagonism at the resent time is the tendency of the Civil Servant to apply every level of the hospital service the methods of personal administration that are suitable for the entral functions of the Ministry but not for the day -day management of individual hospitals or hospital roups

Another possible source of misunderstanding is the ct that in the event of any administrative mishap or stake the Minister accepts public responsibility for e failings of his officers at the Ministry who rightly reserve their anonymity whereas if a board or com ittee is criticised not only is its good name publicly stake but also that of the administrator It is not ggested that this position should be altered but it is portant to recognise that there is this difference in ublic accountability

The situation is made more difficult by the fact that he Ministry has assumed responsibilities which it was ot originally intended that it should, and for which ivil Service methods are not properly suited. The need r extreme financial economy has—understandably but one the less regrettably—led the Minister to impose a ntrol over administrative detail, and this control has roused considerable antagonism

Though the financial situation is largely responsible, art of the explanation can be traced back to the theory put forward by Mr Bevan in the debate on the National Health Service Bill during the Committee stage (col 208) when he said

> I must ask hon. Members to assume that the wide body of knowledge at the disposal of the Ministry of Health, with the very many technical advisers available both voluntary and otherwise is much more likely to produce a good hospital design than a local management committee.

Although in this case the theory was applied only to hospital design, it has in fact been applied to many other aspects of the hospital service—and indeed of the whole national economy—and it can be briefly summarised in the now famous remark that ' The gentleman in Whitehall really does know best

Logically there is something to be said for the idea that the Ministry of Health should be the centre of knowledge able to draw upon the experience and wisdom of technical advisers and experts, who in turn, by virtue of their position at the heart of the nation wide organisation of all the health services are theoretically in a position to see all sides of every question and to provide all the best answers. In practice however this theory is open to several criticisms Firstly there is a danger that the advice of experts appointed and controlled by the Ministry will be heard and accepted to a greater degree than that of the voluntary part time advisers, who are generally chosen from practising members of the professions and organisations concerned with hospitals Secondly the Ministry experts are not necessarily the most competent persons in their field and are therefore not necessarily the persons to set the standards for the whole hospital service Thirdly the experts by reason of their work at the centre tend eventually if not rapidly to become out of touch with the day to-day realities of hospital work Fourthly when this theory is applied to the details of hospital work—as it has been applied by the Ministry—it means that the experts bring upon themselves an enormous load of work, which inevitably leads either to inordinate delays or to insufficiently considered decisions and which also throws a great strain upon the Ministry officials concerned, not only because of the pressure of work but also because the methods of the Civil Servant are hardly suited to this type of administrative work Fifthly, the application of this theory introduces a large element of standardisation and uniformity in the service though desirable to a limited extent on grounds of economy these attributes of centralisation can only too easily produce unwanted rigidity and inflexibility in an essentially humanitarian service which must always be changing and developing if it is to provide the best care for the patient. Finally—and this is an argument that applies not only to the National Health Service, but also to all forms of central authority —the continued application of this theory of centralisation has an insidious effect upon the spirit of local and individual initiative and responsibility The process is made all the more insidious and dangerous by the almost imperceptible way in which it grows and of the evident reasonableness which which it is invested. As has been said earlier a study of all the circulars that have been issued shows that individually nearly every one appears to be basically reasonable and apposite The objection to the detailed guidance given in these circulars lies not in their substance but rather in the fact that it is the central authority which is in this way usurping the proper functions of the regional and local authorities and their officers. The ultimate effect of this process is inevitably a lowering of the standards and qualities of those who will be attracted to serve either as members or as officers of the boards and committees this in turn will lead to a greater degree of centralisation under the direct control of the Minister and so the vicious circle will go on with increasingly unfortunate results for the patient

Few will deny that "The formulation of policy in its major features" is the proper function of the Ministry, but is it essential for the Ministry (as opposed to a regional board or management committee) to issue detailed guidance on such matters as supply of razor blades to patients, issue of sweets to children, provision of telephones for hospital staff, washing down of walls and paintwork, and detailed control of establishments? Complete standardisation on such matters, and on many others, makes for administrative convenience and tidiness at the expense of individual judgment, initiative, and responsibility Detailed control and advice on these aspects of hospital life could safely and more satisfactorily be left to the individual authorities or their officers This does not mean that the reports of the various statutory advisory bodies should not be circulated to all hospital authorities, but there is no need for these to be accompanied by explanatory memoranda from the Ministry

It is nevertheless clear that powers of central control must be reserved to the Ministry, since the Minister is responsible to Parliament, and hence by necessity must deal with

(1) The "formulation of policy in its major features" and the planning and coördination of policies affecting all branches of the health service

(2) The over-all allocation of the share of the national resources of money, materials and labour to the health service including the major decisions on capital development

(3) The determination of a national salaries and wages structure for the health service

(4) Negotiation, consultation, and direction on matters which are obviously national in application, such as Civil Defence arrangements, health service charges, and proportion of pay-bed accommodation

The acceptance of this pattern of Ministerial responsibility would of itself provide the answer to the question of the responsibility of the regional hospital boards, as put by the Select Committee

> "The Ministry either must decide to give greater scope to the Regional Hospital Boards than they at present enjoy, or alternatively they must move towards re organising the service on the basis that the functions of the Regional Hospital Boards are purely of a planning and advisory nature"

For a definition of the Ministry's responsibilities on these lines would increase considerably the scope of the regional boards There would be a twofold effect upon the administration of the hospital service In the first place the Ministry's officers would be freed from the work of detailed administrative control that they at present exercise, and would be able to concentrate not only on the actual formation of higher policy but also on the duty of seeing that that policy is in fact carried out In the second place, the increased scope and freedom from interference in detail would require of the boards an added sense of responsibility, and the relationship between Ministry and boards would have to be one of trust and confidence rather than of detailed control

The Regional Hospital Boards

Although it seems desirable in almost every way, this delegation of authority from the Ministry to regional boards could lead to the danger that there will be an excess of centralisation at the level of the regional boards

The "regional" approach to hospital development has long been considered the best method by those who have studied the question seriously, as can be seen by reference to the reports produced before 1946 by such authorities as the King Edward's Hospital Fund, Nuffield Provincial Hospitals Trust, and the Ministry of Health In each of these the need for an authority to plan and organise on a wider basis that that open to a local hospital authority has been recognised Nevertheless, the regional boards themselves have been criticised It has indeed been suggested that they should be abolished altogether, but an answer to this suggestion is that put forward by the Association of Hospital Management Committees

> "If the Regional Boards were not there the place would inevitably have to be filled by something else, which would presumably be the regional officers of the Ministry Regional Hospital Boards are essential for the planning of the hospital services, with consequential control of all major capital expenditure, *and for the allocation of senior* Medical Staff, and the distribution of available financial resources, so as to ensure the best comprehensive Health Service throughout the Region Regional Hospital Boards must also have some measure of effective control of Hospital Management Committees who act as their agents There is also the further important point that the Regional Hospital Boards are a safeguard against remote Government control, consisting as they do, like Hospital Management Committees, of voluntary workers with local knowledge"

The need for some measure of regional control is this as necessary as is the need for some central control, and the arguments against excessive centralisation are much the same in either case Now that five years have passed sufficient experience should have been gained to allow a better definition to be made, with the main object of preventing *any increase in centralisation* The regional board's functions should be to deal with those matters which from a practical point of view are best dealt with regionally in the interests of all concerned These functions, already referred to in the quotation above, can be summarised as follows

1 To plan the *hospital and specialist* services in their regions

2 To appoint the members of hospital management committees

3 To appoint senior medical and dental staff

4 To distribute the available financial resources to the hospitals

5 To control major capital expenditure

6 To maintain liaison with other health and hospital authorities—e g, county councils or boards of governors—where common policies require to be agreed *on a regional* basis

7 To act as an administrative centre for matters which are appropriate—e g, tuberculosis service, blood transfusion depots, contractual beds, and Civil Defence

8 To provide certain services for hospital management committees—e g, legal, engineering or architectural advice if required—and to help and advise hospital management committees when appropriate as part of their function of general supervision of the hospital services in the region

In other respects it should be the policy to give to the management committees as much freedom as possible, and to avoid interference in the details of day-to-day administration at present the boards are forced to interfere by the Ministry on occasions, as shown by the circular on Economy in Manpower (R H B (51) 13) Another possible limitation of the freedom of management committees lies in the fact that legally all their officers are employees of the regional hospital board The local management of hospitals, within the financial limits of the funds provided, is the function of the hospital management committees, who should be regarded as the trusted and responsible agents of the boards in carrying out these functions, just as the boards should be regarded as the trusted agents of the Minister This devolution of authority to the members and officers of boards and committees would give them a much *greater sense of* responsibility and usefulness, which would in turn ensure that really able people would still be attracted to serve in the hospital world

Although much of the criticism in this paper has been directed towards the Ministry, it would not be fair to blame all the failings upon the Minister and his officials for the boards and committees themselves are partly to blame Firstly, because, although in theory they are ponsible to the Minister (in the case of boards) or to Boards (in the case of management committees) ne authorities seem to have adopted an excessively ochial attitude which has led them to extract as ch money as they can from the Ministry and spend surplus rather than return it—a most unsatisfactory cedure, which is encouraged by the budgeting methods pted by the Ministry Secondly, because there has n exploitation of the political and emotional aspects he hospital service by some authorities in their dealings h the Ministry Thirdly because it is generally recog ed that the standard of hospital administration has been uniformly high throughout the country urthly because of the attitude of the boards and nmittees to the officials of the Ministry Many hospital horities felt deeply the loss of individual freedom essitated by the National Health Service Act and ered the service with considerable feelings of prejudice d resentment, which have found expression in resistance the Ministry s policy and regulations and in reluctance coöperate with the Minister s officials.

The relationships of the Ministry s auditors with the boards d committees provide an illustration of the general diffi ties that beset all the relationships between the Civil rvant and the hospital authorities. An independent audit a board s accounts is as essential as it is for any public com ny or corporation the fact that the Ministry s auditors o have a right to inquire into methods and practices that ly indirectly affect finance can obviously lead to mis derstandings and resentment unless tact is exercised on th sides, but this activity of the auditors is clearly necessary en one bears in mind that there are few aspects of hospital rk that do not involve finance and also that the auditors emselves cannot enforce any change of procedure but n only report From the auditor s point of view hospitals uld have been more coöperative from the hospitals point view it could be wished that the auditors would be more actical and less theoretical in their approach to any problem d it may be that with more experience they will develop wider view which at present is sometimes lacking The me comment could apply to all relationships between inistry and hospitals.

It is thus evident that there is room for improvement relationships and methods on both sides The lead can me only from the top and if the Minister shows real nfidence and trust in his agents, the hospital boards d committees will show that they are worthy of that ust. Failure on the part of the few would be best dealt ith by prompt and specific action rather than by dated and generalised guidance

Summary

1 There is nothing basically unworkable about the ructure of the hospital service as loosely defined in e National Health Service Act, nor is there any justifi tion as yet for any fundamental alteration to the Act

2. Generally speaking the underlying principles and tentions, as expressed by the Minister in the debates on e Bill, are unexceptionable and sound, although there a potential danger in the wide discretionary powers served to the Minister

3 A policy of administrative decentralisation subject over-all financial control is well suited to a national ospital service, and the statement of policy by the inistry to the Select Committee on Estimates in 1950 rovides a reasonable basis for the administration of the ospital service.

4 Although many aspects of the present financial ystem can be defended the introduction of a system ving hospital authorities some real incentive to effect vings the development of a modified system of block rants for building maintenance and capital expenditure he redefinition of these latter terms and the develop ment of hospital costing and accounting methods provide ssible opportunities for improvement

5 Centralisation has increased unreasonably in non financial matters, and there is now a definite tendency for the Minister to introduce detailed administrative control by circular thus undermining the agency principle of administration originally promised Ministry circulars should be restricted to matters which allow of no local discretion, others matters should be referred to boards for action when and where *appropriate*

6 The necessary difference between the methods and responsibilities of Civil Servant and hospital administrator can lead to misunderstandings and consequent loss of mutual confidence and respect. The Ministry should not add to these potential difficulties by introducing the detailed administrative control for which Civil Service methods are unsuitable

7 A reassessment of the rôle and functions of the Ministry is required in order to halt the tendency to over-centralisation and government by experts.' In such a reassessment the emphasis should be on the maximum possible decentralisation

8 A similar reassessment of the responsibilities of regional boards and management committees should be made with a similar emphasis upon the need to push responsibility out and down to the individual hospital authorities and their officers

9 Last and most important of all is the development of better understanding and working relationships between the Ministry and the hospital authorities. The Minister should lead the way and set the example in this change

ARTIFICIAL HIBERNATION

STUDIES IN FRANCE

A GREAT deal of clinical and experimental work on artificial hibernation " is being carried out in France a bibliography compiled as recently as August contained 165 references The subject was well reviewed at a recent congress in Geneva[1]

This method originated in the work of Laborit a naval surgeon who was attempting to find out whether anæsthesia could be enhanced by the use of drugs The hypnotic and sedative side-effects of Phenergan were well known and appeared to reinforce ordinary anæsthesia Laborit and his co workers carried out many experimental and clinical trials and developed techniques of improved anæsthesia with correspondingly improved surgical results At the same time 'Largactil (R.P 4560) a phenothiazine derivative, was produced by one of the large Continental drug houses This is not only a narcotic and a weak anti histamine but causes a pronounced fall in body temperature and metabolic rate It is to these two latter effects that Laborit attributes artificial hibernation *With the advent of largactil,* Laborit and his associates[2] showed, in exsanguinated dogs, that shock could be averted by hibernation induced by largactil

Clinical application quickly followed In the first instance this agent was used only in desperately ill patients; the rationale was that in severe illnesses a state of shock exists which is combated by hibernation The results were apparently good; and its use was then extended to prevent shock by reinforcing anæsthesia for major surgical procedures It is now being used in various different conditions ranging from normal mid wifery to the treatment of cerebral hæmorrhage in premature infants

---

[1] Medicine and Hygiene Geneva Oct 1, 1953.
[2] Jaulmes, C. Laborit H., Benitte A. *C R Acad Sci., Paris* 1953 234 37

It is in the field of surgery that artificial hibernation is thought in France to have its widest potential usefulness It enables the surgeon to carry out longer and more involved operations, for the risk of operative and postoperative shock is considerably reduced by hibernation In thoracic, cerebral, and cardiac surgery and in the treatment of shock from burns or severe trauma it has already proved of inestimable value

The wide use to which this measure is being put in France today is well illustrated by the recent annual meeting at the École de Puericulture in Paris, the papers included four on hibernation in pædiatrics Ill premature infants and children with various overwhelming infections, all gravely ill with an almost hopeless outlook of recovery, were treated by this method in addition to antibiotic therapy, a significant proportion recovered

This method is still regarded here with reserve, though there is understandable enthusiasm for its possibilities With further trial a more valid evaluation of its worth will be possible

Medicine and the Law

Death in Hospital

AT a recent inquest at Rotherham[1] upon the victim of a traffic accident, the jury, while satisfied by the medical evidence that no possible lack of treatment at the hospital had been a contributory cause of death, recommended that immediate measures should be taken in future cases of injury They returned a verdict of accidental death The coroner observed that it seemed that a conflict of personalities among members of the hospital staff had perhaps created difficulty in deciding the measures to be taken

The deceased was knocked down by a car at 11 P M and was taken to hospital where he died $1\frac{1}{2}$ hours after the accident Dr X, the resident surgical officer, described the patient's injuries He told the coroner that, as it was an orthopædic case, Dr Y, the orthopædic registrar, was sent for He later found that Dr Y had not visited the ward "Had it been my patient," said Dr X, "I should have set up a plasma drip straight away" Dr Z, who took the message to Dr Y, said a radiographer had been sent for, he had outlined the case to Dr Y who had told him that, as it was a head injury and a surgical problem, the patient should be put to bed with a splint to the injury and he would see the case in the morning Dr Y's evidence was a denial that he had accepted the patient so far as the witness knew, the patient was in the care of the surgical ward, he himself could have done nothing except order a splint and await the result of the radiographic examination

The pathologist told the coroner in effect that a plasma drip would not have saved the patient "I honestly feel that a drip could possibly help as a remote chance, but it might help to kill"

The hospital management committee approved a month later, the report of a special subcommittee which had investigated the circumstances The findings were that all possible treatment had been given immediately, that there was no evidence that the conduct of the case was affected by any suggested personal differences existing between members of the staff, that the rules for casualty officers in such contingencies were in all respects adequate to secure immediate treatment, and that they had on this occasion been duly followed

If the facts of the case support the drawing of a moral, they may remind hospital managements of the necessity of making sure that the respective responsibilities of their officers are understood without risk of uncertainty

The Widdicombe File

IV ALL IN THE DAY'S WORK

DEAR HAWKE,

As one who profited by your instruction when you were in the path dept at St Cuthbert's, I was delighted to find you within a specimen's throw, so to speak

As you see, I've ended up in general practice—not really as a frustrated specialist, but because I like a bit of variety and the paths of hospital work seem to get narrower and narrower I've been lucky in joining a partnership (four of us now) in which we all want to provide the patients with as complete and comprehensive a service as we can Hence it's been suggested that I take over a small side room (in the surgery) as a lab and get it going to the mutual benefit of one and all Could I prevail on you to give me some help in the form of initial advice ?

Obviously, I shall have to cut out both time-consuming tests and expensive equipment On the other hand we ought to be able to undertake a limited range of direct pathological tests, which may save the patient a journey, tell us quickly what we want to know, and incidentally reduce the pressure on hospital outpatient departments and laboratories I'm very keen to do this, because it's one of the ways in which general practice can be kept an interesting and satisfying job instead of being allowed to degenerate into a daily grind Osler said that the true doctor should aim at having three rooms in his house well stocked—the library, the laboratory, and the nursery—books, balances, and bairns This letter is to tell you of my plans for the second room, I will say nothing of the first, and the inhabitants of the third speak for themselves, as you will soon find out when (as I hope) you pay us a visit

* * *

The room we have for a lab is small, but it has a sink and running water The local carpenter (a dignified craftsman with a large rhinophyma and a healthy distrust of the Welfare State) is fitting a bench, and we are having a daylight type strip light and a lamp on the bench for use with the microscope The tests I propose to do are as follows

Firstly, urine testing I plan to use the salicylsulphonic acid test for albumin and a 'Glucotest' tablet for sugar, on the ground of convenience and to avoid splashing boiling urine on the bench I have an Esbach's tube for the quantitative estimation of albumin For bile pigments I shall have strong nitric acid, and for acetone, ammonium sulphate, ammonia, and sodium nitroprusside We have a microscope for examining uncentrifuged urine for cells and casts

Secondly blood tests Genuine anæmia must surely be quite common in general practice, chiefly iron-deficient but a few pernicious We already have a Medical Research Council grey wedge hæmoglobinometer, which I'm pretty sure will justify its cost by the speed and accuracy with which one can do a number of estimations I have a technician's tray holding a rack of test-tubes with rubber bungs and numbered labels, each holding 4 ml of 0·04 % ammonia, together with a needle, pipettes for slides, and distilled water and acetone for cleaning the pipettes With everything at hand I find it takes about 90 seconds to take blood into the tube and make a film; then after the surgery, the samples can be put through the hæmoglobinometer at the rate of more than one a minute, the films are stained with Leishman and examined with the oil-immersion lens I feel that I ought to be able to recognise the appearances of iron-deficiency anæmia or P A If I am not sure about a film or come across anything unusual I would like to send nl of blood in a mixed oxalate bottle with an unstained ear for whatever tests you think necessary I don't pose to do red and white cell counts or other more borate tests as they take too long and in my hands uld be so inaccurate as to be useless The sedimentation te must surely be very useful in practice and I have ne Westergren tubes and bottles containing 0·4 ml 3·8% sodium citrate to which I add 1·6 ml of blood n I right in thinking that the only difficult thing about is test is to remember to read the result after the be has stood for one hour?

Thirdly, it seems to me that the Gregersen slide test occult blood in the stools should be simple and luable where there is a possibility of gastro intestinal eration or growth I have a tube graduated to 2·5 and nl., and the drill is

> Pour in glacial acetic acid to the first mark and dilute th distilled water to the second Shake in a benzidine t powder and let it dissolve Then bring a drop of the ution into contact with a spot of emulsified fæces on a de A blue colour developing within thirty seconds means ult blood—whatever the patient may or may not have ten in the way of meat

Am I right Sir? It all seems fairly easy for the res can be collected off a finger stall after rectal amination, or the patient can be told to bring a small mple in a bottle If reliable this should be a very lpful screening test for cases with gastro intestinal mptoms One positive test would show the need for rther investigations and a consultant's opinion, while ree negative tests would, I imagine be pretty good dence against ulceration or growth It should help us see that cancer of the stomach and bowel are diagnosed thout delay, and it should also help us to keep out of spital some of the people with abdominal symptoms se to anxiety and unhappiness. (You can't I suppose commend any handy lab test for these?)

Finally I have the reagents necessary for a Gram's ain with the idea of examining vaginal and urethral scharges for monilia or gonococci I also intend to look r trichomonas in freshly collected wet specimens which ust be more certain as well as more convenient than nding the specimen to the laboratory

'I have half a dozen 10 ml. all glass syringes for taking ood and I'd like to know whether my sterilisation chnique strikes you as all right—viz

> After use the syringes are washed in a detergent ("Tide") d then rinsed thoroughly first in tap water and then in stilled water When dry they are lubricated with liquid raffin and done up in test tubes with needles attached. hoose an auspicious moment and take them to the missus, ho pops them in the oven one hour at 160 C and they are ne

at is my sterile syringe service and it does not really ke up much time

* * *

'These are all the tests I think it worth my trying to dertake they are all simple, need little equipment and ke no longer than it would to make an appointment and ite a letter to the appropriate specialist or laboratory lthough the range is very limited it seems to me to cover large part of the *practitioner's day to day needs* nything more elaborate I would like to send along to m if you are willing; this is likely to include throat abs specimens of pus urine sputum and fæces for cteriological culture and control of antibiotic therapy; mples of blood for sugar and urea blood-counts glutinations and Wassermann tests. May I come to ur lab and collect a selection of bottles, swabs and rms?

'Anyway I look forward very much to meeting you ain,

Yours sincerely
BILL BREWER.

Parliament

Speech from the Throne

REFERENCES to housing and public health figured prominently in the Queen's Speech at the opening of the new parliamentary session on Nov 3 Her Majesty said that her Ministers would continue to encourage the building of houses and schools and would also stimulate a vigorous resumption of slum clearance Legislation would be introduced to facilitate the repair and improvement of existing houses both by local authorities and by private owners Legislation would be proposed to revise consolidate and extend the law on the safety, health and welfare of miners and quarrymen, to provide benefit for certain further cases of disablement from industrial diseases, to amend and consolidate the law relating to food and drugs, and to restrict night working in the baking industry The Road Traffic Acts were being attentively examined with a view to introducing further legislation to improve road safety and promote the orderly use of the roads.

In seconding the Address in reply to the Speech from the Throne Miss EDITH PITT said it was recognised that the success of the housing drive now made it possible to intensify slum clearance and encourage the repair and modernisation of some of the older types of houses. Health was the most important social service, and the treatment and prevention of tuberculosis presented a special challenge and a special opportunity—namely to eradicate this scourge The immediate problem was the need for more beds more nurses and more surgical facilities. It would help to make the most effective use of existing hospital beds if some kind of hostel or intermediate accommodation could be provided for those who needed only limited supervision and perhaps some nursing A recent survey in the Midlands had shown that 15–20% of the beds occupied came within this group

Sir WINSTON CHURCHILL, the Prime Minister emphasised that while new houses were being built at the rate *of 300,000 a year as many were mouldering into ruin* and a far larger number were denied the modern conveniences 2 250 000 houses were over a hundred years old and another 2,000,000 were between sixty and a hundred years old

Mr HAROLD MACMILLAN Minister of Housing and Local Government, said that the time had now come to take up the second part of the housing programme People living in old houses had just as much right to have their conditions improved as those moving into new houses In 1939 it was estimated that 6% of the population were living in unfit or overcrowded houses and although there was much to be done in the way of improving old houses and clearing slums, the national stock of houses and flats was now very nearly equal to the number of separate families 2 million accommodation units had been provided since the end of the war during which some 250 000 houses were destroyed The answer to the question why the housing lists were still so large was twofold First of all higher standards of living had created a demand for a higher standard of housing Secondly there were now far more single people and old people and there were more young married couples most of them wanting a home of their own As to the slums the National Housing and Town Planning Council estimated that about 500 000 dwellings could be classed in this category; there might be even more He had already had informal talks with the local authorities which would be asked to put forward programmes for dealing with the slums

Mr ANEURIN BEVAN said that the Government had brought forward a scheme which had the maximum of political odium and would have the minimum of physical results Not only slum clearance and reconditioning but all rent-restricted houses must eventually become the responsibility of local authorities. Under this system the houses that would be first repaired would not be those which under the Government's formula became profitable for landlords to repair, but those that needed repair first Even if the Government's formula was effective in getting all the repairs carried out it would mean a diversion of resources from other operations

Future of Hospital Registrars

On the motion for the adjournment in the House of Commons on Nov 6, Mr HORACE KING drew attention to the employment problems of hospital registrars He recalled that when the National Health Service began many doctors took up posts as registrars in the belief that the consultant service was to be expanded In fact it had been expanded to a remarkable extent But it had been impossible to foresee how great the expansion would be, and in 1951 it was discovered that there were more registrars than the health service could absorb In the long run, he thought, everyone agreed that Mr Bevan had made a wise decision when he decided to cut the intake of registrars and to approximate the intake to the number of consultant posts likely to become vacant from year to year But Mr King was concerned with the 300-400 senior registrars who had already entered this apprenticeship and who now found it difficult to obtain posts of any kind

When the cut was made the then Minister of Health had said that registrars who failed to obtain consultant posts need not be alarmed because they could go either into the Colonial Service or into general practice But Mr King pointed out that though doctors were undoubtedly needed overseas these posts were more suitable for younger men The men he had in mind were now 35 to 40 years of age, mostly ex-Servicemen with family responsibilities, who ought to be settling down, not starting a career in a new world On the other hand, when a registrar's period of hospital service came to an abrupt end and he tried to get into general practice his position became really alarming Mr King knew of men with excellent academic qualifications who had not even got on to the short list of candidates for a vacant post

Vacancies, he understood, were filled in the first place by a joint committee consisting of members of the health executive and the local medical committee The former might be laymen the latter were entirely members of the medical profession This joint committee prepared a short list, sometimes interviewed the candidates, sometimes did not On this local joint committee local doctors could exercise the fullest influence over the laymen The short list then went to the Medical Practices Committee, a national body consisting entirely of doctors, which finally made the appointment If a wrong was being done by the health service to the registrars, it was being done by the members of the medical profession Polarity had grown up between the general practitioners and the consultant service He hoped that the gap would be bridged, it would be a pity if in the meantime the general practitioners were hurting these hospital registrars because of their emotional reactions to being kept out of consultant work in general hospitals He appealed through the Minister to the medical profession on behalf of this group of deserving and able men The solution of the problem lay largely in the hands of the profession, this dominated the Minister's committee which, independent of any control, filled partnership and assistant posts as they became vacant

Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Ministry of Health, agreed that more doctors had entered the senior-registrar grade than could be absorbed into consultant posts It had now been agreed with the profession that there should be an intake of approximately 270 new senior registrars each year They had met the inflation in the number of senior registrars by increasing the number of consultant posts, and by temporarily extending some of the senior-registrar posts to give those men a fair opportunity to obtain consultant posts

The number of senior registrars in the early years of training was now closely in line with the number agreed with the profession The number in the later stages of training was still in excess of the vacancies, and there was a limit to the vacancies which could be made for them But those in the senior-registrar group had had a greater opportunity to find specialist vacancies in the past five years than they had before, because of the increased number of vacancies, or than they were likely to have in the future The suggestion that consulta were staying on longer was not borne out by the fa The number of consultants who were 65 and over were still in the service in 1950 was 120, in 1951 and in 1952, 78

The largest problem was undoubtedly the classification of registrars It was never thought all those who took registrar posts could become sp The development of medical treatment and of the pital service generally had called for many more and there was a grave shortage of this grade in areas The remedies must include an increase in time and part-time registrars For the part registrar they must look to the general particularly those who had just started in practice were prepared to do part-time work while their practice The increased need for full time in the hospital service meant that to the registrar's appointment was a normal step in the part of his career before going into public health or to the Colonies Many of them would have to into medical posts outside the hospitals

As to the suggestion that there was di against registrars when they attempted to get general practice, Miss Hornsby-Smith thought too much emphasis had been put on the adv vacancy, which was usually for a single-handed prac often vacated by a practitioner of long-standing had a fairly substantial list It was not surprising preference was often given to the man who had general-practitioner experience But 60% of the for general practice were in partnerships. It was c for our doctors to practise in partnership and she this custom would not lessen Registrars must beyond the advertised vacancies and realise that larger field lay in other appointments For in in March and April this year, 154 new partners taken into partnership, 238 assistants became with their principals, but there were only 24 a vacancies A registrar's first steps in general pra would more advisably be taken in a partnership having obtained general-practice experience, he be a strong candidate for a single handed p It was usual and reasonable for the committees to men with general-practice experience for these vac and it was a little unreasonable for an ex registr expect to step straight into a large, advertised handed practice There was no evidence that d were discriminating in any way against ex regis many of whom had obtained posts

QUESTION TIME

Masks Against Fog

Mr SOMERVILLE HASTINGS asked the Minister of what researches had been made to determine how much sulphur oxides and other gaseous contents of fog were from inspired air by the use of a dry gauze mask Dr P STROSS asked a similar question —Mr IAIN MACLEOD There has been extensive research, both here and abroad protection from the toxic solid and gaseous contents of different conditions Respirators to achieve this have known for many years, they are of rather elaborate types, something like those used in the Forces. But problem of the "smog" is that of persons—and partic old persons—suffering from weaknesses of the lungs or as last winter showed, and further research is need determine what respirators could be safely worn by people for long periods This is going on actively amongst outpatients of a large hospital As to surgical gauze ma chiffon scarves, I am advised that they would be of littl no value in absorbing the toxic gases, although like any comparable form of improvised protection they would some of the solid particles in a fog

Byssinosis Benefits

In answer to a question, Mr R H TURTON, Mini Pensions and National Insurance, said that up to Oct 1953, the number of claims under the pneumoc and byssinosis benefit scheme in respect of byssinosis about 100 for disablement and 25 for death Awards 85 and 21 respectively

In England Now

Running Commentary by Peripatetic Correspondents

'THERE'S nothin' so queer as scent cept a woman! d Mr Jorrocks and the more I watch my blood unds manhunting the more I share his view, at least on the first half of the comparison

Having once dabbled in the mystics of E.N.T. I ought I understood the physiology of smelling When untryside offered long days of hunting foxes, hares, d otters familiarity with scent bred that cocksure ntempt which traditionally precedes a fall.

The day we started keeping bloodhounds marked the astening descent to true humility It soon became parent during training that the hounds were teaching far more than we could teach them and when the bble of our false pride was well and truly pricked we out to recapture the atavistic echo of a sensory echanism long surrendered by Man in his evolutionary urse of differentiation.

Bloodhounds detect colder scents than probably any her animal because over a thousand years of selective eding have been focused on their noses But do they ssess a wider spectrum for olfactory stimuli or have y merely a more delicate sensory appreciation? hink that they have both Certainly they can recognise ells beyond the olfactory range of man just as the s of dogs can register notes far above man's upper lt of hearing Even when a human being picks up pungent smell of a fox on a still autumn morning is probably not the scent which the foxhounds run d I have grovelled in vain on the ground to try and pture a whiff of the scent of man which a bloodhound ns so confidently So, too, they have an amazing licacy of appreciation of faint odours. Many hounds ve hunted lines several days cold, and I have even tched my old bitch dig the kit of victims of a mountain ident from the snow after 47 days; but perhaps persistence of scent is one of its vagaries

Although hounds must live in a world of smells, they ve a well-developed discrimination even to differen ting between individuals of one species Just as young thounds will change on to a fresh fox so young odhounds will change on to a fresh human quarry til training has impressed upon them that they must k to one scent There is also some scent memory chanism which carries the hounds over checks and pires them to cast for themselves and pick up the trail in without changing. This mental concentration imposes oticeable strain on hounds and they show fatigue far excess of the physical effort involved

When the snows are thick it is quite instructive to tch a bloodhound bury his nose into the quarry's tprints snuffle loudly, and then bound forward to eat the process On the other hand a fresh cross wind l cause the hound to run the line some ten to forty ds parallel with the quarry's path and in the still n of evening the drift of cool air down the fellside l lift the head of a bloodhound to mark a man even arter of a mile uphill

used to wonder whether a man's personal scent was ained after death or whether it was replaced by the erie cadaver smell with which we are all familiar ving watched my own hounds locating bodies I eve that the personal scent lingers long after death m such morbid contemplations it might be more reshing to reflect upon the second half of Mr Jorrocks's mparison though possibly more ungallant

* * *

It was a bad mistake for a young doctor in a new ctice: the whole village must now know that I have fused two easily distinguishable growths. While the tman and I were admiring each other's allotments ointed to his parsnips and remarked on the strength l vigour of his celery It was doubly unfortunate that was the postman, for the story was round the village h the morning delivery

For a time I didn't dare to show my face in my den; but grass and hedges will grow and eventually ad to emerge I started by cutting back the hawthorn ge. As often happens when one is engaged on routine repetitive work my thoughts began to wander and I found myself considering the perennial problem of the industrial medical officer—how to persuade the workmen to wear their protective clothing how to convince them that accidents will happen even to them, how to eradicate the juvenile fantasy that it is cissy to put on goggles, gloves, or aprons Just then my friend the postman came down the road "You want gloves for that job" he said 'Those thorns can give you a nasty hand'

* * *

On Friday morning I turn first to this column and after that to the Letters to the Editor There I am always prepared for a recurring irritation About a third of the letters begin I have read with interest or 'I am interested : and I can't think why Does not the correspondent realise that it is superfluous to announce his 'interest'? The mere fact of his putting pen to paper shows that. It might of course be appropriate to observe that he has read with amusement admiration enjoyment, approval, surprise consternation contempt, disgust, regret sorrow, dismay, or any one of a hundred expressions of his emotion But interest! His communication would be all the better for the omission of this presumably apologetic explanation of his request for the usual valuable space.

* * *

Some years ago I was rash enough to buy a book. I forget what it was—something to do with first-aid, probably, or the care and maintenance of the golden hamster Anyway I asked them to charge it, and from that moment dates my inferiority complex. They have got it into their heads that I am a good prospect, an easy touch and not a week passes but they send me a catalogue of *New and Forthcoming Scientific Books* Every fourth or fifth week I receive a catalogue (slightly foxed) of *Old and Rare Scientific Books*, and every two or three months—so bewildering is our English climate—there arrives the *Autumn List of Scientific Books*

It is these catalogues that depress me, particularly the mathematical section These chaps don't fiddle around with experiments They *know* It is impossible to read the brief chapter headings without a stirring of the emotions. The Hopf Invariant Fibre Spaces; the Hurewicz Theorems how they would reverberate in the mind of the reader! Or again Some Fundamental Properties of Noetherian Rings, Residue Rings and Rings of Quotients; A New List of P multiplied Laplace Transforms these are the very stuff of science, the life's blood of the future

When I have read through the catalogues I often go along to the animal house and look at all those rabbits and feel quite low in my mind. Last week I felt so badly about it I went out and bought another book.

* * *

I have always been fascinated by reports of treatment by hypnosis, but Sheila, my wife is a confirmed sceptic.

Both of us have a phobia of spiders. I never touch the things if I can avoid it but luckily Philip our four-year-old son likes spiders (particularly the big ones) and will keep them clasped firmly in his fist until persuaded to put them in the garden

I suppose it was because Philip showed such disregard for them that I decided it was time to overcome Sheila's fears. One night, just as we were going to sleep, I told her in my most compelling tones using the most modern abreactive technique that she could see large and horrible spiders everywhere, great enormous monsters all over the room, but never again would she be frightened by these lovable and handsome arachnids. I was still saying this when slumber overtook me

The next night we saw a huge spider I went straight to it, picked it up played with it in my hands and threw it out of the window I looked round with the light of victory in my eyes and saw that Sheila had fainted

* * *

I have never entertained any strong views on geriatrics or my geriatric colleagues but now all that has changed I overheard a nurse trying to explain to a confused 80 year-old that she was safe in hospital. In hospital? the old lady croaked incredulously The nurse nodded in triumph 'Oh! is that all? Thank goodness for that. I thought I was in hell'

Letters to the Editor

ETHICAL STANDARDS IN CLINICAL RESEARCH

SIR,—I am very glad that Dr Fisher has called attention last week (p 993) to the increasingly common failure to observe one of the primary rules of medical ethics

The privileged position which doctors hold in society depends entirely on the trust which people have in the purity of their motives This is stated explicitly in the international code adopted by the World Medical Association in 1949 "Under no circumstances is a doctor permitted to do anything which would weaken the physical or mental resistance of a human being except from strictly therapeutic or prophylactic indications imposed in the interests of the patient" There is no justification here for risking an injury to an individual for the possible benefit to other people, as enunciated by Dr Holt as his guiding principle Such a rule would open the door wide to perversions of practice, even such as were inflicted by Nazi doctors on concentration-camp prisoners The magnitude and crudity of their "experiments" must not be allowed to blunt sensitivity to breaches of the medical ethic made on a smaller scale and with greater plausibility Of this nature are experiments performed upon condemned criminals, with or without the victim's consent, upon conscientious objectors to military service, upon persons with chronic mental illness or deficiency or incurable disease of any kind, and all procedures, whether therapeutic in intent or not, which are not designed with the sole intention of improving the lot of the individual upon whom they are performed Only one exception can be allowed—i e, when the experimental subject is an adult whose judgment is not impaired and who freely gives his consent No child must ever be the subject of such an experiment

I could quote many examples, published without comment or attempted justification in the medical press of English-speaking countries, of the failure to observe this rule Here are three, all quite recent

(1) Potentially harmful doses of ageno given to children in an orphanage, in order to see whether such doses were toxic

(2) The use of patients with incurable cerebral tumours as experimental subjects for finding out whether intrathecal aureomycin was injurious the experiments involved multiple lumbar punctures

(3) Attempts to reproduce dangerous syncopal attacks in a child in order to obtain graphic records

It is clear that the assumption by doctors of scientific methods and techniques calls for critical examination of the uses to which these methods are put The scientific material of the clinical research worker is human life Some discussion of the issues involved took place in a symposium at the Chicago Medical School in 1952[1]

I should like to see a resumption of the practice by which all doctors upon qualification were required to make a declaration of adherence to the medical ethic There is need for a revised, more simple form of the Hippocratic oath, relevant to the circumstances of the 20th century For some time the ethics subcommittee of the Medical Association for Prevention of War has been occupied with such a revision, and I give, for the sake of discussion, the tentative and interim results of this attempt

At the time of being admitted to the medical profession, I swear to regard my duty as a doctor as overriding all other obligations, in particular I will not allow considerations of race or nationality, nor my own personal profit, to interfere with my performanc that duty, namely

(1) To promote, with all the means at my comma civilised standards of life and health throug the world

(2) To direct all my work to the preservation of and the relief of suffering, and under no circ stances whatever to use my medical know to harm any person, nor take part in any ex ment involving risk of injury, without myself of the understanding and freely g consent of an adult subject, nor without consu my colleagues upon the value and necessity such an experiment

(3) To coöperate in every way possible with doc and health-workers in all countries both in of peace and in time of war to work at all for the preservation of peace

(4) To communicate freely to all doctors an coveries which I believe myself to have concerning the nature, cure, or preventio disease

(5) Never to abuse the position of privilege in my profession has placed me, to respect confidences of patients but not to allow su to endanger the health or lives of others

I will be ready, if need be, to sacrifice my health, or life, rather than be unfaithful to this oath

Bickley Kent DUNCAN LE

INCISION FOR ACUTE APPENDICITIS

SIR,—The report by Mr Ewing and Mr W (Oct 24) of one case of acute appendicitis is conv proof that this humble malady has not passed unn by the Postgraduate Medical School, but some d may justifiably remain as to whether the complica described would have been averted by a muscle-spli incision

They advise this incision in "all cases in which appendicitis is diagnosed," and add that the param incision should not be made a cloak for slovenly diag Is it not time that our teaching schools cease encourage the hypocrisy implied by "a con diagnosis of appendicitis"? Space precludes a descr of the 21 different abdominal catastrophes which I personally mistaken for acute appendicitis, but case report may serve to emphasise the stresses to a slovenly diagnostician may be exposed

A lady of 52 was admitted with a ten-day history of abdominal pain, she had a tender mass in the right ili a temperature of 101 6°F, and a white cell count of per c mm She did not long survive an incision which to shortest possible route into a leaking aneurysm of abdominal aorta

The criss crossing gridiron incision cannot be d satisfactorily, it frequently becomes infected, and gives very inadequate access to the pelvis and no at all to the rest of the abdomen It remains th incision in advanced pregnancy, and for cases in w tenderness is maximal in the flank It is satisfactor young men with mild symptoms

Battle's incision is very rarely followed by he because divarication of the recti, which weakens midline and paramedian wounds, crowds the m into the lateral part of the rectus sheath

The unrivalled exposure afforded by the param incision makes it, on balance, the most satisf "standard" approach If it is made well below umbilicus (in young women an obvious hollow marks spot), quite a short incision gives excellent acce pelvis where a hidden collection of pus can easi overlooked When an abscess is present in the right fossa, the rest of the abdomen can be packed off b the exploring finger releases a gush of pus A la llows in a small percentage of cases but the repair lvised by Cattell has robbed the operation of much of s difficulty

The poor cosmetic result of the paramedian incision is rtly concealed when the patient is examined on a couch the erect position an ugly transverse fold appears at e upper limit of the scar For this reason I have taken using the *Pfannenstiel* or *bikini" incision for* xploring the lower abdomen in girls whose face and gure may play a part in their fortune It gives very od access, is immune from hernia and is much ppreciated

Barnet General Hospital. V J DOWNIE

SIR,—If I say that the plea of Mr Ewing and r Monro for the use of the gridiron incision in pendicitis is to me what Mr Punch calls ' another impse of the obvious, I am not unmindful that many rgeons still make large paramedian holes and that the minder is salutary Many think that one cannot al with the appendix through a gridiron incision in ung children and even in babies, whereas the procedure not nearly as difficult as it in theory might appear have pointed out elsewhere[1] the advantage of this cision in dealing with long standing recurrent abdominal pain in children where the diagnosis is not firm it where parents are kept in continual suspense lest e next attack may be a fulminating appendicitis. By e time it is decided that intervention is necessary any sion in any other part of the abdomen will almost rtainly have manifested itself and through a gridiron cision one can see and remove the appendix examine the esentery *for adenitis and withdraw enough small bowel* exclude a Meckel s diverticulum These are the three kely organic causes of such recurrent pain when the dney has been excluded

The morbid result described by Ewing and Monro llowing a paramedian incision reminds me that someone ice said that no-one who had had a paramedian incision er played on the centre court at Wimbledon It may an overstatement but the sequelæ to large laparo mies especially in the presence of sepsis, make me ink that any exception is likely to be a rarity

On Mr Shemilt s dictum (Oct. 31) that the abdomen ould never be drained in appendicitis I will confine yself to parliamentary language and only register ief as he also in time will certainly if he persists with ch practice in children It is the drain that is left in o long that does harm

London W 1 CHARLES DONALD

SIR,—Mr Shemilt s letter moves me to support a plea for Battle s maligned incision It has served e well for forty years I do not recommend it for ening an abscess or for very fat patients, and I prefer oblique muscle-cutting incision for the high lying trocæcal appendix

With Battle s incision the nerves are clearly seen and ould not be cut Their distribution seldom conforms the diagrams in anatomy books Caution must be ed in extending the incision upwards but, after ntrolling the deep epigastric vessels it can be carried wn to give excellent access to the pelvis Hernia is re after Battle s incision and my impression is that it is ore often seen after McBurney s

Colt and Morrison[2] in an inquiry into the relationship tween the death rate after operation for acute appendi itis and the incision used found that much the west mortality occurs with the Battle incision Their ticle is worth studying

THERAPY OF DIARRHŒA IN CHOLERA

SIR,—The diarrhœa and vomiting of cholera lead rapidly to a great loss of body fluid and electrolytes and ultimately to progressive shock which is often irreversible and fatal During the last few decades workers on cholera have been trying every available remedy to check this diarrhœa, but without any appreciable success The sulpha drugs[1-3] and the antibiotics chloramphenicol[4 5] terramycin,[6-8] and aureomycin[9 10] have little or no effect in checking the diarrhœa or in reducing the mortality rate of cholera, although the antibiotics can render the stools bacteriologically negative Consequently the present tendency in cholera therapy is to disregard the diarrhœa and to concentrate on the replacement of fluid and electrolytes.[9 11]

During the severe epidemic of 1953 in Calcutta the cholera patients in my ward were given by mouth the crude juice from the leaf of a common plant of Bengal called pathorchur " (*Coleus aromaticus*) a short green plant about 2 ft high with thick crenate leaves giving off a camphor like odour (see figure) The juice from the leaf is a greenish fluid with a pleasant taste and smell and without any deleterious effect on any physiological system The dosage consisted of the following hourly doses: 1st dose 4 teaspoonfuls 2nd and 3rd doses 2 teaspoonfuls each If the diarrhœa continued after eight hours on the first day the doses were repeated in the evening On subsequent days the above doses were repeated unless there was constipation. Every 6th case in order of admission was tested as a control. The 40 controls were not given any leaf juice but the routine treatment of shock and other complications were just the same as in the treated cases In addition, the control cases received four doses daily of a routine suspension containing kaolin (gr 30) and bismuth carbonate (gr 20) in each dose The following results were obtained

(1) Of 200 treated cases the diarrhœa was checked within twenty four hours in 40% within forty-eight hours in 74%. and within seventy two hours in 92 5% Of 40 controls the diarrhœa was spontaneously checked within twenty four hours in 5% within forty-eight hours in 12 5%, and within seventy two hours in 30%

(2) Stool cultures showed a peculiarity—i e. rough colonies of the vibrio appeared comparatively early in the second culture after twenty four hours leaf juice therapy The proportion of rough colonies to smooth continued to increase in the successive cultures the smooth colonies being scanty

HEMENDRA NATH CHATTERJEE

DRIED BONES

SIR,—I hesitate to intrude on your columns with so small a matter, but surely Dr Davies and Dr Harvey (Oct 24) are maligning the Far East in fathering upon it their anthrax-infected bones (even though they were shipped from somewhere East of Suez) East is East, Near East is the Levant, Middle East Babylonia, and the Far East Malaysia and the China Seas These bones came from India and Pakistan, which are no sort of East on this reckoning One of the minor snags of the partition is that it has left us with no convenient name for the subcontinent, but to misuse the term Far East is no answer to the problem

Postgraduate Medical School of

BERNARD LENNOX

ASPHYXIA IN THE NEWBORN

SIR,—Professor Pask (Oct 31) quite properly draws attention to the defects in the explanation and diagram in my letter of Oct 17, and I am sorry that he feels he has been misquoted The details of the apparatus could be only briefly described in a letter, so perhaps I may add some further explanation

The endotracheal tube used most often is a McGill size 00 The needles are those supplied by the Canadian Red Cross and are somewhat larger than the needle in the standard giving set Rebreathing in the anæsthetic sense—namely, to conserve an anæsthetic agent—is not required The infant does not rebreathe to any great extent, for the supply of oxygen is more than adequate Sometimes the fingers of the glove have been taped off and the glove attached to a branch piece of suitable diameter, and then rebreathing was really taking place However, most often the setting of the oxygen supply is such as to inflate the glove partly This works well as an indicator of spontaneous respiration, as well as being all that is necessary for gentle inflation It should be remembered that an infant face mask is manufactured and widely used It fits the standard Boyle's machine and in the resuscitation of infants it is commonly used with the adult rebreathing bag

My diagram showed a tube leading to an oxygen supply but the oxygen is not connected directly two release needles intervene and a reducing valve supplies oxygen at a low pressure A water manometer is not used, for I think that there is a real risk that the first (and most important) spontaneous inspiration might result in the aspiration of water The endotracheal tube is never a tight fit in the infant trachea and allows further leakage Obviously, great care must be taken to avoid undue pressure

Just as no anæsthetic agent is safer than the person who employs it, so no emergency ventilation method is foolproof Neonatal asphyxia is a desperate emergency and forthright methods are justified There is certainly a risk of overinflation, as Professor Pask emphasises, but it depends very largely on the diligence and care of the operator At all events, complete anoxia is a graver risk

It is unfortunately true that the securing of an airway by an accurately placed endotracheal tube may not be sufficient Positive pressure ventilation is a vital and immediate necessity in some cases of neonatal apnœa, and with the widespread use of pethidine, apnœa du to narcosis is possibly on the increase

Post mortem examinations are carried out after al neonatal deaths, and the pathologists have been particularly requested to report in detail any respiratory injury No such injury has been found On the oth hand, lungs have been described as completely atelectati when adequate inflation had been used

The intravenous needles are a more substantial safeguard than may be immediately apparent In 194 some medical officers of fighter squadrons were asked to submit reports on an oxygen economiser then in u I used a Spitfire Mk Vb kindly loaned by No 71 Squadr at Martlesham A too generous setting of the oxyge cylinder—which in those days was out of the reach o the pilot behind his armour-plating—provided me wi personal experience of overinflation I used intraven needles to provide a blow off, and know that it is a sound and practical device I gather from the accou of Lieut Commander Lithgow's recent troubles in Nort Africa that oxygen-valves still give annoyance sometim

J NOEL JACKSON

CERVICAL SPONDYLOSIS SIMULATING MOTOR-NEURONE DISEASE

SIR,—Dr Morris's letter (Oct 31) on the diagnosis of motor neurone disease seems to imply that a brisk jaw-jerk is the absolute criterion of this condition, and th a normal jaw-jerk is incompatible with a diagnosis of motor-neurone disease I am sure, however, that Dr Morris will agree that in "progressive muscular atrophy" no alteration will be found in the jaw jerk until a la stage in the development of the process, and indeed the reflex may never be abnormal Even in the "amyotrophic lateral sclerotic" form of motor neurone dis briskness of the jaw jerk may follow briskness of ot reflexes only after an appreciable interval

To complete the factual record, however, may I that in our cases of cervical spondylosis the jaw jerk not increased

L A LIVERSEDGE

RISKS OF TONSILLECTOMY

SIR,—Mr McKenzie's article last week stirs memo a quarter of a century old As house surgeon in a London children's hospital I was responsible for t twice weekly reception of 12 children, aged from 10 years, and for their care during the three days their stay Anæsthesia was by ethyl chloride (2 in a bag) *tonsillectomy* was by blunt guillotine u used as a holder whilst the forefinger of the appro hand was swept round the end of the erect guillo and invariably found the capsular plane I was ca during the night, as occasion demanded, to c hæmorrhage by pressing directly into the tonsillar with a prepared swab the size of a walnut and so in spirits of turpentine During my six months residence no vessel had to be ligatured and no died of hæmorrhage or was given a blood transfus I do not attribute this to the turpentine, but to *fact that the vessels were torn* by the dissecting finger

With regard to pain following tonsillectomy, I r the removal of the tonsils of a girl of 18 One t was held in the blunt guillotine and removed by sweep the forefinger behind the guillotine, and the other t was removed by dissection she had pain in dissected fossa and none at all on the guillotined The reason is that the pharyngeal muscles are sul to long continued and repeated damage on the dis side, whereas a blunt guillotine, slowly closed, t the capsular plane with little trauma, the finger n disrupting the various vessels which bind the t to the pharyngeal wall

---

[12] Chatterjee, H N *Lancet* 1952 ii 90

How can one be sure that the blunt blade is engaging capsular cleavage? I was taught that when the de is in the right plane a concavity appears on anterior surface of the anterior pillar during the w action of closing the tip of the index finger of disengaged hand presses on the anterior pillar ite gently and keeps the tonsil posterior to the blade

ongtown Cumberland.   ROBERT RUTHERFORD

MILLI-EQUIVALENTS

SIR,—Dr Ennis's letter last week is discouraging to ose who advocate the m eq per litre terminology because its simplicity in a certain context—that of the "struc ral" electrolytes of body fluid, such as Na K Cl and CO_2 These substances are of importance chiefly in lation to one another in maintaining acid base and motic equilibrium within body fluid It is therefore gical to express their concentration in a terminology hich not only allows rapid comparison of one electrolyte ith another but also is simply related to the osmotic fect exerted by their sum. The advantages of the .eq per litre terminology have led to its general option in scientific work in this field the same merits ould commend it for general clinical use, but the draw ks mentioned by Dr Ennis certainly must be nsidered

1 The same article may express some blood constituents in .eq. per litre and others—including acid and basic radicles— a direct weight/volume terminology; this tends to con sion in understanding and in dispensing

In answer to this, no one suggests that the m eq per re terminology should be applied universally but only those electrolytes whose relationship to one another d to the osmolarity of body fluid is specially important ithin this field clarity is promoted and not lost, and it is sirable that *replacement solutions* should also be scribed in this nomenclature especially as mixed ctrolyte solutions such as Na K chloride and lactate lutions, are now being used The practical manage nt of electrolyte problems is then made easier not ore difficult

2 "The actual estimates of such substances by a laboratory *in terms of mg. per 100 ml*

This depends on the laboratory The methods of imation are in fact based on chemical equivalence or physical properties of the elements estimated and it quite as easy to use m eq per litre standards as any hers.

Most clinicians think in terms of mg per 100 ml., and w the normal blood levels so expressed.

This may be so but most people who become interested electrolyte problems or have interest forced on them responsibility find it worth while to make the small rt of self-education needed in order to reap the antage of ready comparison of different electrolyte centrations.

Our present knowledge of the part played in health disease by the electrolytes which Dr Ennis cites gests that their relationship to one another and to y water is of overriding importance rather than their ividual concentrations. The m eq per litre termin y aids this appreciation, and its application to clinical blems for it gives us our results in the units observed the electrolytes themselves in their interactions with another In the interests of our patients, we should re ourselves the struggle with incommensurate units ich is implicit in a weight/volume terminology in this ticular field.

Department of Medicine
niversity of Manchester   D A K BLACK.

SIR,—We should be grateful to Dr Ennis for wing attention to the question of marking solutions of ctrolytes for replacement therapy in m eq per litre instead of in g per litre Much of the value of using m eq per litre in reporting blood values is lost when transfusion solutions are not similarly marked The use of m.eq makes it simple to find how much of a solution is required to correct any given deficit.

Dr Ennis's argument that m eq per litre should not be used because some clinicians are accustomed to a different system, and (by implication) are unwilling to introduce any improvement, is unfair to them On such a basis we ought still to measure concentrations of replacement solutions in grains scruples, and drachms per fluid ounce, since these terms were more familiar to our ancestors than the metric ones Admittedly the retention of two systems of measurement introduces risk of error the logical action is to abandon the use of g per litre for measuring ionic substances in transfusion solutions.

Dr Ennis is wrong in stating that ionic substances are measured in the laboratory in terms of mg per 100 ml No chemist ever thinks in such terms when dealing with acids and bases the use of equivalents being much more convenient If clinical pathologists and clinicians would *make the effort, once for all, to change to similar terms* they would wonder why they ever used g per litre

Biochemistry Department,
Royal Infirmary Glasgow   J C EATON

THE INSULIN MYTH

SIR—As the one who introduced insulin therapy into this country almost twenty years ago I should like to comment on Dr Bourne's very sound article last week We must thank him for drawing attention to the fact that the "insulin-situation" makes a good deal of difference (this even holds good for E C T) and has in itself been responsible for many insulin recoveries reported Also for putting forward that prognostic and *diagnostic criteria have altered in the course of time so as* to obscure direct comparison of contemporary results with those of the pre-insulin era. I foreshadowed this[1] when remarking after a visit to Vienna that the prognosis of schizophrenia in that city at any rate appeared to be unworsening in proportion to the number of insulin recoveries reported from Poetzl's clinic alluding then to the *frigid reception that Sakel's method* was *receiving* from his local colleagues. I considered such welcome to bode well for the method's future—a view since amply confirmed by the subsequent fate of both convulsion treatment and leucotomy

I wish I could agree with Dr Bourne, though that insulin offers the schizophrenic no more benefit than does E.C.T we all should be spared a good deal of nervous energy if this were so That E C T does more for the chronic case than insulin is well known. In the more or less acute case, however, the position is reversed It is clinical experience that counts here despite all figures adduced to the contrary The uninterrupted recovery under insulin now in its twelfth year of even a single case of "hopeless" schizophrenia of two years' duration after the fruitless application of 39 E.C.T.s (by the same physician) should be enough to convince anyone that insulin is the superior treatment here[2] In particular, I have found the spontaneous insulin convulsion (which unfortunately cannot be produced at will) far more potent therapeutically than any form or number of induced convulsions, whether given on top of hypoglycæmia or otherwise

Isleworth Middlesex.   H PULLAR-STRECKER.

SIR,—Despite Dr Bourne's vigorous attack many psychiatrists will continue to use insulin-coma treatment in selected cases of schizophrenia until a *better method becomes available for they are fortified* by occasional successes. Dr Bourne will surely not deny that there are at least a few patients who remain seriously disturbed for weeks or months, despite electro-convulsion therapy and despite a good deal of attention from nurses and doctors, *until* insulin coma treatment is started If the improvement then occurs in an expected time relationship to the start of treatment, it is legitimate to conclude that the treatment *causes* the improvement

---

[1] Münch med. Wschr 1936 p 649
[2] Pullar-Strecker H *Med Pr* 1944 211 319

This is the most elementary and generally applicable criterion on which to assess the value of a treatment It is surprising that Dr Bourne should have neglected it, for, although it contains a judgment of probability, it is in many respects a better criterion, when applied to each case in turn, than are the remission rates in relatively large and heterogeneous series of cases upon which Dr Bourne relies He should perhaps have taken warning from Dr Eysenck's strange experience, for a similar study of remission rates in psychoneurosis led Dr Eysenck to conclude that psychotherapy was ineffective [1]

Insulin coma treatment does relatively little damage That it has caused remission in a significant number of cases when other methods have failed justifies its use, although it has often disappointed Its immediate effects are worth while, even should it be shown—as it has not yet been—that it is ineffective in the long run

RECURRENT PAROTITIS

SIR,—Seven years ago I described 13 instances of this disease [2] My experience is almost identical with that noted in your annotation (Sept 26)

Rambam Government Hospital
Haifa Israel

WALTER FALK

DIAGNOSIS OF HYPERPARATHYROIDISM

SIR,—Reviewing my book, *Clinical Endocrinology*, in your issue of Oct 31, you say

> " for the diagnosis of hyperparathyroidism the aspirant will need more explicit information than is here provided surely we are not going to turn these problems over to another specialist, the chemical pathologist ? "

With regard to the first half of this sentence, an account of the disturbances of calcium and phosphorus metabolism in hyperparathyroidism has been given in detail and I should have thought could be understood by the intelligent reader, for whom the book was written The second half of your statement is truly remarkable, since hyperparathyroidism cannot be diagnosed without the services of the chemical pathologist Would you be so good as to inform us how you would arrive at the diagnosis without such assistance ?

St Bartholomew's Hospital
London E C 1

A W SPENCE

*** Dr Spence says on p 238 of his book, under the heading *diagnosis*, that " in hyperparathyroidism there is always a negative balance of calcium " This is where his aspirant might be led into error Bony changes may be absent in some severe cases of hyperparathyroidism, as Dr Spence reminds us on p 236 , this suggests that some patients maintain their stores of calcium well In fact, Dr Spence's references include an instance where the measured balance of calcium was indeed strongly positive as long as the intake of calcium was liberal The diagnosis of hyperparathyroidism may require, among other things, estimation of the urinary excretion of calcium while the intake of calcium is low , and the normal findings might also have been given But the intelligent reader can of course find, under the heading *metabolic disturbances* on p 237, that " the urinary excretion of both [calcium and phosphorus] is increased even when the intake of calcium and phosphorus is low " He mig not, however, realise that this was a condition for t test

The physician knows what radiographs to ask for an can usually interpret the findings, In the same wa when he is a clinical endocrinologist he can conduct own investigations, though he may be ignorant of chemical techniques , and he can interpret the labor results This is clearly also Dr Spence's view, since gives detailed instructions for conducting, for example the Kepler test Of course these tests cannot be without the services of a laboratory, nor indeed was suggested Some of the best work in clinical endo logy is being done by chemical pathologists, opinion, when available, is valued, but with few except they do not look after the patient —ED L

ISOLATION OF PSYCHIATRIC HOSPITALS

SIR,—In your annotation of Oct 3 (p 716) you the isolation of psychiatric hospitals and the need for association—embracing all psychiatric hospitals in country—that would provide a means for regula change of ideas

It may interest your readers that in Surrey an Inte hospital Psychiatric Association was founded just two years ago which locally fulfils this function hospitals forming the association are B Belmont, Cane Hill, Horton, Long Grove, The Netherne, St Ebba's, West Park, and the C Laboratory

The association holds regular clinical mee organised by each member hospital in rotation, at whi cases from the hospital are presented and papers read members of its staff The success of the meetings in first two years has brought forth a desire for a furt strengthening of clinical links between the hospi Recently intramural clinical conferences have thrown open to the staffs of all the member hospita the association General practitioners from the area the staff of neighbouring general hospitals attend association's meetings

We feel that there is an advantage in keeping association of this kind within the bounds of not large an area

West Park Hospital

JOSEPH ZELMANOWITS
Hon. secretary, Surrey Inter-hosp
Psychiatric Association.

GOUT

SIR,—As advocate of " interval " salicylate the in the treatment of gout,[1] I was naturally interested Dr Marson's paper [2] on the continuous salicylate tr ment of the disease to which your leading artic Oct 31 refers

As interval therapy now is under criticism, may I that it was suggested at a time when salicylate the took second place to the more toxic drug, cinchop because given in this way sodium salicylate cause better uric acid excretion without toxic effects It admittedly a compromise and not a complete answ the problem of the therapy of chronic gout, nor a rently is continuous salicylate therapy, which still al fluctuations in the serum uric acid level and occas attacks of acute gout, and is not always practic because of salicylism While I shall certainly try Marson's method, I was disappointed to find apparently dismissing the interval therapy on the re of only one case, thrice tested for three days out of with salicylates, which showed moderate and symp less rises in serum uric acid in the therapy inter The method has, after all, been tried and found val

experienced workers[3,4] If given for four days in ven, as I also originally suggested the upward fluc ations in the serum uric-acid level are likely to be orter and smaller, while the chances of salicylism main slight

In a longer account of my investigations on the bject,[5] I also noted the importance of a good fluid take during therapy for a patient on salicylate with high intake of bland fluid—e.g., 2400 ml daily—would ss about twice as much uric acid as during the same erapy with a low fluid intake (1200 ml) I was dis pointed to find little emphasis on the influence of fluid take on uric acid elimination during the salicylate erapy of chronic gout either in Dr Marson s paper or your leading article

Edgware General Hospital
Middlesex.

G H JENNINGS

DOSAGE OF ANÆSTHETICS

SIR,—Recent correspondence in your columns reminds that I have been using intravenous barbiturates the induction of anæsthesia for over twenty years—ree-quarters of that period in the tropics

I have observed that the temperature of the solutions the factor which appears to determine the rapidity d duration of their action

Before we had air-conditioned hospitals I noticed in e hot weather that the onset of the action of hexo rbitone (Evipan ') was more rapid than in the cold ason and in consequence less was required over a given riod.

More recently working in an air-conditioned hospital Arabia, where my patients were Americans, Arabs edouin and town dwellers) Britons Indians Iraquis alians and Red Indians I found I had to make no owance for race—merely the usual care to assess e patient s physical condition.

It would be interesting to know whether other servers have had the same experience

MEDICAL MEMBERSHIP OF HOSPITAL BOARDS

SIR,—The Institute of Public Administration held a nference in London on Oct 28–30 They discussed the alth service According to your report of the conference, John Grant said that doctors employed in a hospital ould not be appointed to the board of that hospital *This remark* your report continues *brought more plause than any other at the session* I italicise this mark lest its significance be lost. From it we can see ich way the wind is blowing The functionaries wish employ doctors in their hospitals but they do not wish em to sit at their boards to give counsel

Having reminded you of this report I feel like leaving u and your readers to chew it over without further mment, but I cannot resist a few questions Is it no nger true that patients come to hospitals to seek the vice and help of doctors ? Can you recall any major vance or reform of clinical policy within a hospital ich has been brought about without medical advice ? ve our British hospitals so bad a record over the past years that we must discard the method by which their verning bodies have received advice ?

I am all for reform where and when it is necessary but e applause of the conference of the Institute of Public ministration denotes something more than a desire r reform.

Newcastle upon Tyne

Public Health

Estimate of Future Births

THE Registrar-General s final estimate for live births in England and Wales during the December quarter is 155 000, and his provisional estimate for the March quarter 1951, is 170,000 giving an estimated total of 325 000 babies in the six months There were 158 029 live births registered in the December quarter of last year and 171 705 in the March quarter of this year—a total of 329 734 This year s number of live births registered in the 160 Great Towns up to Oct 31 was 332,083 compared with 328 062 in the same period a year ago

Sterilisation of Feeding-bottles

The Medical Research Council has completed an investigation[1] designed to assess the relative value of boiling or hypochlorite treatment for the sterilisation of infant feeding bottles and teats The laboratory experiments showed clearly that sterility of both bottles and teats could be regularly achieved either by boiling or by immersion in a hypochlorite solution, provided each method was correctly used Each method is simple but requires careful attention to detail; the complete submersion of the teat is a point often overlooked

B C G Vaccination of School children

The Minister of Health has informed local health authorities in England and Wales that he is prepared to approve schemes for giving B C G vaccination to children before they leave school; and the Department of Health for Scotland announces similar plans. Since 1949 when official permission for its use in this country was first given B C G vaccination has been offered to nurses and medical staff in hospitals and (at the discretion of chest physicians) to the close [illegible] of patients with tuberculosis. Local health [illegible] will themselves decide whether they wish [illegible] make the vaccination of school-children. Wh[illegible] be done it will be offered in coöperation with the education authority to children of thirteen [illegible] The consent of parents will always be [illegible] first. In a circular[2] setting out the details [illegible] scheme the Minister suggests that in [illegible] with the teaching staff it should be [illegible] suitable talks and discussions to eliminate [illegible] and misunderstanding that may arise among [illegible] as to the meaning of the injections and loca[illegible] reactions. The Minister has also sent to medical officers of health a memorandum discussing [illegible] of B C G vaccination

Notes and News

RIPENESS IS ALL

Oxford congregation has raised the retirement age of all members of the university teaching and administrative staff to 67 This is a first positive gesture towards the longer working life which we are all now invited to attempt[1] Cambridge[2] (says our Oxford correspondent) is the customary half pace behind Prof R B Braithwaite, at a meeting of the university senate on Nov 3, said that no educational advantage would be secured by following the "bad example" of Oxford, though he agreed with the Cambridge University council that wider provision should be made for using the services of retired officers He was supporting the opinion of the Master of Jesus, who maintained that not only would it be bad for the university to keep lecturers longer at their posts but also it would increase the violence of competition among younger men Mr Glyn Daniel, PH D, of St John's was one of a minority in favour of raising the retiring age to 67, the advantage of retaining brilliant teachers, he said, far outweighed the risk of prolonging the service of a few inadequate ones

Certainly, as Sir Zachary Cope pointed out at a recent conference,[3] nobody knows when a man is going to age, least of all the man himself Nevertheless the air at our great universities is known to have a peculiar preservative effect on good intellects (rather like that of the desert sands on mummies) If there is any place in the world, other than Oxford, where it should be safe to extend the working life for a couple of years, that place is surely Cambridge A compromise, however, might be wisest When a man retires at 65 the university might be given the option of inviting him to stay on from year to year, if he is willing, for as long as he seems to be contributing to the best interests of the university

ANÆSTHESIA IN CHILDREN

In his presidential address to the section of anæsthetics of the Manchester Medical Society, on Oct 29, Dr H. E Pooler discussed the administration of anæsthesia to children He described a psychiatric inquiry which had been made at Chesterfield Royal Hospital to assess the effect of tonsillectomy on a group The routine included careful preoperative preparation of the children by the anæsthetist, who explained to them why they were there and what was going to happen to them A syrup containing atropine and chloral hydrate was given by mouth before the operation Anæsthesia was induced by intravenous thiopentone followed by nitrous oxide, oxygen, and trichlorethylene The tonsils were then removed by the guillotine method. Dr Pooler suggested that the analgesic effect of trilene was carried over into the recovery period, so that the pain from the throat was subdued until the child had recovered from the effects of the thiopentone, thus minimising the postoperative restlessness commonly noted after premedication with barbiturates A psychiatric examination of 116 of these children showed that 3 4% had emotional sequelæ during the first three weeks after discharge from hospital

EDUCATION IN NUTRITION

Addressing the Food Education Society in London on Nov 4, Dr John Yudkin, professor of physiology at Queen Elizabeth College, remarked that food evoked irrational and violent emotions "There is hardly anyone who, however ignorant, however biased, is not quite certain that his own views are absolutely and completely valid, and that those who hold opposing or even somewhat different views are at the best misguided, at the worst irresponsible and malicious" Professor Yudkin touched on three common nutritional fallacies One was that purified or refined foods were necessarily inferior to the more "natural" foods if it was necessarily better to eat whole foods such as the whole wheat, because that was how it grew, why not be logical and insist on eating bananas whole too, with their skins? The second fallacy was that of "percentage composition"—that is, that the only important thing about a food was what proportion of nutrients it contained, irrespective of the amount of the food eaten. The third important fallacy was that of the panacea "I am one of those who believe it is practicable, even in our own life time, to ensure that every one of family of mankind should get the amount and the food which will satisfy his physiological needs" But th who put their faith in, and advocated, any single cours action towards this end were putting off the day when th necessary vast, multiple, and interrelated attack would made on this most urgent problem Turning to the new Lond University degree of B SC (nutrition), courses for which ha just begun at Queen Elizabeth College, Professor Yu expressed the belief that "we can produce real nutrition —not merely chemists or doctors or agriculturalists who h a leaning towards the nutritional aspects of their own specia And if we can do this, there will at last be a chance that wider education in food and nutrition—to school-chil domestic science teachers, doctors, nurses and, eventu the public as a whole—will one day be undertaken by th who have themselves studied nutrition as an integ scientific discipline and not by those who have receiv from third and fourth hand"

CONFERENCE OF ARMY PATHOLOGISTS

On the first day of this annual conference, which was in London on Oct 22 and 23, technical demonstrat arranged by the professor of pathology, were given at Royal Army Medical College, and an administrative mee was held in the War Office On the second day the follo civilian guest lecturers spoke Dr G D Lumb (Effect Radiation on the Cellular Structure of Tumours), L P Garrod (Function of the Bacteriologist in Connect with Routine Bacterial Chemotherapy), Prof A C. Fr (Gastro-intestinal Dysfunction in Man), Dr P L Mol (Hæmolytic Diseases of the Newborn), and Dr E Kath Williams (Hæmatological Control of Personnel Exposed Ionising Radiation)

FOUNDATIONS FOR A CLEARING-HOUSE

Dr N Howard Jones,[1] director of the division of edit and reference services of W H O, describes its task "documentation" as ranging from editorial selection publication (which implies ability to appraise the value of paper, with the help of expert referees) to bibliog analysis designed to make published work available to interested reader (which implies knowledge of journals, the use of indexes, bibliographies, and abstracting serv Since the work is international, the staff of the division in a team of full time translators, for though papers may the division in any known language, they are presented W H O publications in two working languages—English French

The publications of this division of W.H O include no their periodicals—the *Bulletin of the World Health Orga* the *Chronicle of the World Health Organisation*, and *International Digest of Health Legislation*—but also the *Technical Report Series* and *Monograph Series*, the *Records of the W H O*, and the supplements to the Bu Their library, now six years old, contains 30,000 volum various languages mainly on public health subjects receives 1500 current journals It gives library servi request to any of the member countries, as well as W H O headquarters' staff It seems that in this divisi may have the beginnings of that international bureau— central clearing house for scientific information—which many have foreseen as a necessity

IMPERIAL CANCER RESEARCH FUND

The Fund's new laboratories at 48, Lincoln's Inn Fie a few doors from the Royal College of Surgeons of Engl were opened on Nov 10 In 1951 the council of the F decided to support special investigations on outstan problems in the pathology of human cancer The work closely connected with the surgical treatment of canc it has been carried out for the past two years in the departm of pathology of the Royal College of Surgeons But accommodation soon proved inadequate for the gro needs of the newly recruited research staff, and the F asked the college for permission to rent its house in Linc Inn Fields and to equip it as a clinicopathological labora And the work will now have a place of its own in the splend equipped premises at no 48

The new laboratories were formally opened by Prof. H. Dean, F R.C.P, chairman of the council of the Fund, oke warmly of the help given to the venture by the Royal llege of Surgeons. The research work at Lincoln's Inn will r under the supervision of Prof Geoffrey Hadfield F.R.C.P e Fund will encourage the interchange of staff between coln's Inn and its existing laboratories at Mill Hill which main under the direction of Dr James Craigie F.R.S

Mr J J Mason Brown will deliver the Dr John Burns ture in the hall of the faculty 242 St Vincent Street on dnesday Nov 18 at 5 P.M. He is to speak on the Surgical atment of Anomalies of the Alimentary Tract in the wborn.

sociation of Surgeons of Great Britain and Ireland

Next year the association's annual meeting is to be held Leeds on May 13 14 and 15 The subjects to be discussed lude hiatus hernia ulcerative colitis exophthalmos and odenal diverticula

berden Society

Sir Russell Brain F.R.C.P will deliver the Heberden ation on Friday Dec 4 at 3 30 P.M at the Royal College Surgeons, Lincoln's Inn Fields, W C 2 He is to speak on ondylosis: The Known and the Unknown

itish Council for Rehabilitation

On Wednesday Nov 25 the council is holding a one-day ference in association with the department of social dicine of the University of Sheffield at the university medi library starting at 10 A.M The subject will be Can abilities be Overcome?

ited Hospitals Festival Choir

This choir conducted by Colin Ratcliffe is to give two certs at the Royal Albert Hall during 1954 The first, art's *Requiem*, with the Philharmonia Orchestra, will be Jan. 20 and the second probably Verdi's *Requiem*, with London Symphony Orchestra, during the summer hearsals are held every Thursday between 6 P.M and P.M at the Church of the Most Holy Trinity Brompton mbership is open to anyone who works in a hospital, and plications will also be considered from anyone who has done in the past There are vacancies for all voices. Further rticulars may be had from the secretary Flat I 93 Lexham rdens W 8

Royal Society

The Copley medal has been awarded to Prof A J Kluyver FOR MEM R.S., for his contributions to the science of microbiology

Royal Institute of Public Health and Hygiene

Sir Henry Dale O.M F.R.S is to deliver the Harben lectures at the institute 28 Portland Place London W 1, at 5 P.M on Monday Tuesday and Wednesday Dec 7 8 and 9 His subject will be Changes and Prospects in Medicinal Treatment

Alfred Adler Medical Society

At a meeting to be held at 11 Chandos Street London, W 1 on Thursday Nov 12 at 8 P.M Dr T F Cotton will speak on the Psychological Element in Cardiac Disease

Robert Roesler de Villiers Award

On Oct 20 this award was conferred on Dr Ludwik Gross chief of research at the Veterans Administration Hospital Bronx New York, for his work on leukæmia.

Society of Public Analysts

At the next meeting of the society to be held on Wednesday Dec 2 at Burlington House London W 1 at 7 P.M Prof C H Gray will give a lecture on Recent Advances in Medical Chemistry

World Congress of Catholic Doctors

The main subject chosen for discussion at this congress, which is to be held in Dublin from June 30 to July 4 is Demography Further particulars may be had from the secretariat of the congress at Veritas House 7 Lower Abbey Street Dublin

London Jewish Hospital Medical Society

At a meeting of this society to be held at 8 30 P.M on Thursday Nov 20 at 11 Chandos Street, W 1 Sir John Parkinson will speak on Syncope

International Gerontology Congress

The 3rd Congress of the International Association of Gerontology is to be held in London on July 10–23 1954 The chairman of the British organising committee is Prof R E Tunbridge and the British organising secretary is Mrs. A Humpage Tavistock House South Tavistock Square London W C 1

Society for Cultural Relations with U S.S R

Dr Ilina chairman of the executive council of the Medical Workers Union in the U.S.S R., and Dr Kazantseva director of the Institute of Pædiatrics of the Soviet Academy of Medical Sciences, are visiting this country; and this society has arranged for them to address a meeting intended for doctors, on Monday Nov 30 at 8 P.M at the house of the society 14 Kensington Square London W 8 They are to speak on pædiatrics in the U.S S R

Provision for Old Age

The committee which, under the chairmanship of Sir Thomas Phillips, is reviewing the economic and financial problems arising from the changing age-structure of the population (but not with specific levels of provision for the individual pensioner) would welcome evidence from individuals, institutions, and organisations. Evidence in the form of written memoranda should be submitted to the joint secretaries of the committee Treasury Chambers, Great George Street London S W 1 not later than March 31

British Cardiac Society

The autumn meeting of this society was held in London on Oct. 30 under the chairmanship of Sir John Parkinson Short communications arranged by Dr Samuel Oram the secretary included papers on sodium chloride and cardiac muscle; pulmonary distensibility and respiratory work in mitral stenosis; cardiac output during exercise measured by the Fick method; pulmonary venous drainage into the right heart via a persistent left superior vena cava entering the left innominate vein; and the ballistogram in coronary artery disease

Diary of the Week

NOV 15 TO 21

Monday, 16th

Postgraduate Medical School of London, Ducane Road W 12
4 P.M Prof F J Nattrass Difficulty in Diagnosis of Epilepsy

Royal Eye Hospital, St George's Circus, S E 1
5 30 P M Miss J M Dollar Ophthalmic Nursing and Post operative Treatment.

Institute of Cardiology, National Heart Hospital Westmoreland Street, W 1
9 30 A.M Sir John Parkinson Pain in the Chest

Hunterian Society
8 30 P M (Apothecaries' Hall, Black Friars Lane E C 4) Proposers Mr A Dickson Wright Dr R. R. Bomford Opposers Sir Malcolm Hilbery, Q C, Dr H Joules That Tobacco is a Blessing

Tuesday, 17th

British Postgraduate Medical Federation
5 30 P M (London School of Hygiene and Tropical Medicine, Keppel Street, W C 1) Prof W T Astbury F R.S *Proteins and other Biological Macromolecules*

Society of Apothecaries of London, Black Friars Lane, Queen Victoria Street E C 4
4 P M *Dr Peter Bishop Disorders of Sex*
5 15 P.M Dr W S C Copeman Chronic Rheumatic Diseases—*a Revaluation of Remedies*

Institute of Dermatology, St John's Hospital Lisle Street, W C 2
5 30 P.M Dr E J Moynahan Connective Tissue

West End Hospital for Nervous Diseases, 40 Marylebone Lane, W 1
5 30 P M Dr D Gordon Neuroradiological demonstration

Manchester Medical Society
4 30 P M (Medical School, University of Manchester) Sir Zachary Cope Birth of Modern Medicine

Wednesday, 18th

Postgraduate Medical School of London
2 P M Prof F G Young, F.R.S Endocrine Control of Carbohydrate Metabolism (First of two lectures)

Royal Society of Medicine 1, Wimpole Street W 1
8 15 P M *Section of General Practice* Dr John Fry Prof J G Scadding Dr Peter Kerley Common Lung Infections in General Practice

Royal Eye Hospital
5 30 P.M Mr J F P Deller Optics of Direct and Indirect Ophthalmoscopy

Royal Institute of Public Health and Hygiene, 28, Portland Place W 1
3 30 P.M Dr G B Mitchell Heggs *Dermatology in Industry*

Institute of Dermatology
5 30 P M Dr J O Oliver Bacteriology of Skin Diseases

Institute of Urology 10, Henrietta Street, W C 2
5 P M Mr D I Williams Retention of Urine in Childhood

Eugenics Society
5 30 P M (Burlington House, Piccadilly, W 1) Mr G Aird Whyte, Dr C P Blacker Possible Future Activities of the Eugenics Society

Thursday, 19th

Royal College of Physicians Pall Mall East, S W 1
5 P M Mr B Ifor Evans D LIT Science and Literature (Lloyd Roberts lecture)

Royal College of Surgeons, Lincoln's Inn Fields W C 2
3 45 P M Dr B E Heard Sites of Common Malignant Tumours (Erasmus Wilson demonstration.)

College of General Practitioners
5 45 P M (Society of Apothecaries, 14 Black Friars Lane, E C 4) Dr Stephen Hadfield Medical Ethics and the *Pitfalls of General Practice*

British Postgraduate Medical Federation
5 30 P.M. (London School of Hygiene and Tropical Medicine) Prof G W Harris F R S Stress and Thyroid Activity

Postgraduate Medical School of London
11 A.M. Professor Young Endocrine Control of Carbohydrate Metabolism (Second of two lectures)

Royal Army Medical College Millbank S W 1
5 P M Sir Stanford Cade Modern Conception of Treatment of Cancer

OF THE TREASURY MEDICAL SERVICE

his report is one of a series on the epidemiology of nary disease Study of coronary heart-disease[10] ests that there has been a true increase of it, and this is not due simply to an increase of coronary roma. The atheroma it seems, is the basic condition e heart-disease but other conditions are necessary the complex of atheroma, thrombosis, and the city of the heart to deal with these in relation to the ands made upon it, all need to be studied

rveys have been made from the Social Medicine earch Unit to gain some knowledge of coronary heart-ase as a problem in public health and in the hope ncovering social factors which may be favourable or vourable to its occurrence Observations on a group edical practitioners[12] indicated that such epidemio al study can be carried out with relatively small bers, and that it may be rewarding The present rt extends this study to other workers and describes findings among them Readers are referred to the ious papers where the possibilities and limitations his type of investigation are considered, and points heory and method are discussed in some detail

CORONARY HEART DISEASE IN DIFFERENT OCCUPATIONS

London Transport

he occurrence of coronary heart-disease in certain ps of weekly paid employees of London Transport cutive during 1949 and 1950 was studied by special ngement between the unit and the Chief Medical er and Staff Administration Officer of London sport Executive The experience of drivers and uctors of the Central (red) buses, the drivers and uctors of the trams and trolleybuses, and the motor and guards on the Underground railways was rved. About 31 000 men aged 35 to 64 were lded. These groups of staff were chosen because the bers in each grade were large and the groups were ogeneous as regards occupation

investigations of this type two sets of facts are red

Facts about all the episodes of coronary heart-disease were recognised during the period under review and t the workers concerned

) Facts about the populations to which these workers ged.

his information was obtained in the manner described w

Part of the general study of industrial morbidity being by the London Transport Executive[13] all sickness nces of any duration for these 31 000 employees are ded in a Central Record of Staff Statistics maintained by Staff Administration Officer Medical diagnoses are ned from general practitioners and hospital certificates, from the London Transport medical officers who examine before they return to work if their absence exceeds ty-eight days. In addition cases of heart-disease with absences of any duration are so examined. All diagnoses are coded by the International three figure code.[9] Details of all deaths and of all retirements due to ill health are also recorded and the medical causes are similarly coded Copies of the death certificates were available, as were the diagnoses of the London Transport medical officers for ill health retirements. Routine checks are imposed in the Central Record of Staff Statistics to ensure accuracy of data

By special arrangement for the present inquiry all absences, ill health retirements, and deaths, the diagnoses of which were assigned to any code number from 420 to 434 (inclusive) were reported to the medical department for detailed scrutiny and cases of coronary heart-disease, presumptively atherosclerotic, and doubtful cases for consideration were then notified to the unit. (It is of course to be appreciated that all clinical presentations of the disease whether occurring on or off duty were included.)

From the Central Record of Staff Statistics population counts in appropriate age-groups for each occupational group were available at the beginning and end of each year the investigation covered

RESULTS

Incidence and Early Mortality

Men may retire from work because of coronary heart-disease so information from industrial sources on

TABLE I—FIRST CLINICAL EPISODES (INCIDENCE) OF CORONARY HEART DISEASE IN WEEKLY PAID STAFF (MEN AGED 35–64 INCLUSIVE) OF LONDON TRANSPORT EXECUTIVE, 1949–50

Ages (years)	(1) Angina pectoris		Coronary thrombosis				Total incidence	
			(2) Coronary occlusion—myocardial infarction		(3) Immediate mortality

60–64	6	*1·2*	19	*3·8*	9	*1·8*	34	*6·9*
Total no of cases	22		63		34		119	
Standardised rate at ages 35–64 incl		*0·4*		*1·2*		*0·7*		*2·3*

First clinical episode = clinical onset of disease = the first recognised and recorded attack of coronary (ischæmic) heart-disease. This was taken to be the same as the first absence from work ascribed to coronary heart-disease All sickness absences of any duration were recorded and all deaths are known. The experience of the men during 1949–50 was observed concurrently and related to their personal records with London Transport Executive and predecessor organisations. Only episodes which began in 1949 and 1950 were included

The type of first clinical presentation is taken from the final diagnosis for the first absence from work with London Transport Executive which was ascribed to coronary heart-disease. There were three main types (1) angina pectoris or of effort causing sickness absence for more than 3 days (2) "coronary thrombosis" —coronary occlusion—myocardial (cardiac) infarction causing sickness absence for more than 3 days (3) Immediate mortality in which are included sudden deaths from coronary heart-disease deaths occurring on duty or during the first 3 days of the first recorded absence from work for coronary disease Cases of "coronary insufficiency" &c., are included with "coronary thrombosis" in (2).

Rate of first clinical episode—Rates in this report are usually average annual rates per 1000 The rate of first clinical episode, or attack, may be termed the "incidence" Since the incidence of individual types will be considered the total rate is better described as the total incidence and is the sum of the rates of (1) (2), and (3) above

The *rates* are standardised for age to permit comparison of the experience of the various groups of workers. The base is the male civilian population of England and Wales in mid 1949

Throughout these tables the numbers of cases are in roman type *rates are in italics* No *rates* are calculated for less than 3 cases.

X

episodes of it later than the *first* is liable to be incomplete We are therefore dealing at present only with the *first absence from work* because of coronary heart-disease, this first absence being regarded as the first clinical episode Table I and fig 1 set out the "incidence"—that is the rate of occurrence of first clinical episodes in the men who were studied The disease is uncommon till 45 years of age, as the last columns of the table show, and from then the incidence rises steadily to 6 9 per 1000 per year at 60–64 years of age

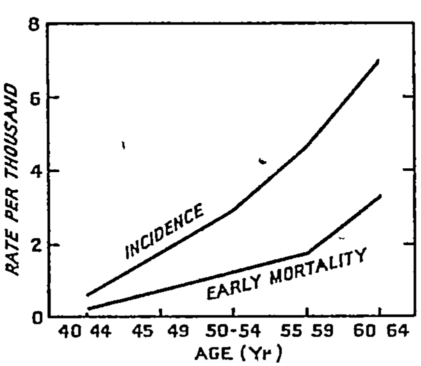

Fig 1—First clinical episodes (incidence) of coronary heart-disease, together with mortality in the first three months, in weekly paid male staff of London Transport Executive in 1949-50

There were three main ways in which the disease first presented itself clinically

1 As *angina pectoris,* representing almost one fifth of all the cases

2 As an attack of "*coronary thrombosis*"—coronary occlusion—myocardial (cardiac) infarction that was not rapidly fatal about one half

3 As "coronary thrombosis" causing death in the first three days of the first clinical episode (here called "*immediate mortality*") between a quarter and a third of the total

Angina of effort, as expected, is rarely diagnosed under 50 years of age, on the other hand, there is no particular tendency for the rapidly fatal cases to occur at younger ages The highest incidence of angina is in men in their late 50s

Fig 1 sets out also the deaths from coronary heart-disease that occurred among these men during the first three months of their clinical disease This "early mortality," as it will be called, rises to 3 2 per 1000 per year at 60–64 years of age Far more deaths occurred "immediately," in the first three days of the clinical disease (34 deaths, table I), than in the rest of the first three months (a further 15 deaths), a finding that agrees with that of the medical practitioners previously studied [12] The standardised rates are 0 7 for "immediate mortality" and 1 0 for the total "early mortality" (49 deaths)

Early Prognosis

Table I shows that over a quarter of all diagnosed cases were fatal in the first three days (34 of 119), this "case-fatality" is fairly stable in each age group In all, about 40% of the first clinical episodes of the were fatal during the first three months (49 of The size of this proportion may surprise those experience is limited to hospital medicine, but it be realised that many of these cases would not be in hospitals unless they were B(rought) I(n) D(ead).

The early prognosis, of course, varies with the manner in which the disease first itself, angina pectoris being the most benign form the point of view of fatality Only 1 of the 22 men presenting with angina died in the first three of the clinical disease, compared with 48 of the (63 + 34, table I) who presented as cases of " thrombosis"—myocardial infarction The ad of those who first present with angina of effort is clear for the three months observed. Other ev shows that this advantage continues for some least It seems that when coronary heart-disease presents clinically as angina of effort the prognosis same as in men who have survived the dangerous weeks of a first attack of "coronary thrombosis myocardial infarction

THE EXPERIENCE OF DRIVERS AND CONDUCTO

Our main object was to seek for relations betwee kind of work men do (understood throughout this in the sense of paid employment) and the incidence them of coronary heart-disease The inquiry therefore designed to show up differences in the of different occupational groups Two years' data obtained for the workers on central buses, trams trolleybuses, and preliminary examination of the (table II) suggested that coronary heart-disease be differently in the drivers and in the conductors brief, angina pectoris was relatively commoner among conductors, rapidly fatal "coronary thrombosis" the drivers 13% of the first episodes among the d took the form of angina—or were so diagno compared with 39% in the conductors Contrari the "immediate" deaths accounted for 31% drivers (25 "immediate" deaths in 80 cases) as 19% in the conductors

In table III the *annual rates of incidence* are cal for ten year age brackets, and *standardised rates* (the population structure of England and Wales basis) are also presented the more readily to comparison between groups of different age compo It will be seen that the total incidence is higher drivers (2 7 compared with 1 9) and there is a sugg that the disease appears at a younger age in More remarkable, the immediate mortality is over as high in the drivers On the other hand, the in of angina is twice as great in the conductors (0·8 per against 0 4) These trends form a pattern wh seen at each ten-year age group, the sole exc being that the one man with angina under 45

TABLE II—TYPE OF FIRST CLINICAL PRESENTATION OF CORONARY HEART-DISEASE IN DIFFERENT OCCUPATIONS AGED 35–64 INCLUSIVE) OF LONDON TRANSPORT EXECUTIVE, 1949–50

Definitions as in table I.
Cases as in table II

* †† $0{\cdot}001 < P < 0{\cdot}01$ (testing the difference between the drivers and conductors in the distribution of the number of cases among the three types of presentation).

ver (As a matter of fact with this exception the tern was found in each of the six five year groups in 35–64) The present type of inquiry is not suitable considering the niceties of morbidity diagnosis. should however be noted that the diagnosis of ngina pectoris is likely to be a self-correcting one, l if rest pain appeared during the first recognised ess from coronary disease the diagnosis stood a d chance of being amended at one of the several tinies of each case that took place during the inquiry a routine measure the final and most serious diagnosis any episode was used in drawing up the tables, and re was ample opportunity to change the diagnosis he light of experience

able IV redistributes the data Column 3 is the total dence again Column 2 gives the mortality during first three months, and it shows that the higher tality among the drivers in the first three days of disease already noticed in table *III* (*0 9 compared* h 0·4) continues for the rest of the first three months, total early mortality rates being 1 3 and 0 6 The y case-fatality among the drivers is almost 50% of 80) compared with 30% in the conductors (9 of leaving the rate of survivors, column 1 the same in h groups.

oncluding then and from the more interesting point iew the conductors had less coronary heart-disease n the drivers, and the disease seemed to be appearing them at a later age What disease the conductors was less severe: they had a smaller early case lity as well as a lower incidence and therefore they a substantially lower early mortality rate On other hand, the conductors had so much of their more ign type of disease in the form (or diagnosis) of ina pectoris that they had absolutely as well as tively a higher incidence of angina than the drivers

DISCUSSION

Four questions arise Is this kind of analysis worth ing at all? Is it likely that the differences which emerge mean anything? Do they suggest any answers likely to be relevant to the ætiology of coronary heart disease? And do they indicate any further questions?

Reliability of Observations

The method of investigation involved primarily two sets of physicians—the men's own general practitioners, and the medical officers of London Transport Executive In addition, there is documented "confirmation" by a specialist, or a hospital or in a few cases only, by an electrocardiogram in over 90% of the non fatal cases this suggests that there was a reasonable standard of diagnosis Because of the methods of collection of data in London Transport all diagnosed cases are likely to be included The main point however is that this is an epidemiological study of the experience of different occupational *groups* There is no reason whatever to suppose that the standard of diagnosis, whether good or merely adequate, or the completeness of ascertainment, will differ in the groups being studied The population consists of men from the same part of the country, served by the same health and welfare services and living in broadly similar social circumstances during the same period of time Conditions of sickness absence and sickness benefit are similar throughout It seems reasonable and worth while therefore to compare the experience of various groups within London Transport

Their Significance"

The main finding is that the conductors have a pattern of incidence of coronary heart disease different from that of the drivers Is this a chance phenomenon? Statistical tests suggest that it is unlikely It is also worth recollecting that although numbers of cases are too small for many rates to be calculated, the distribution of the various types of first presentation of coronary heart disease differs in the conductors of *central buses* from that of the drivers of central buses (table II) likewise the distribution of cases in the *tram and trolleybus* conductors differs

TABLE IV—EARLY OUTCOME OF FIRST CLINICAL EPISODES OF CORONARY HEART DISEASE IN DRIVERS AND MALE CONDUCTORS (AGED 35–64 INCLUSIVE) OF CENTRAL BUSES, TRAMS AND TROLLEYBUSES OF LONDON TRANSPORT EXECUTIVE, 1949–50

Definitions as in tables I and IV

The postal workers were observed for 1949–50 the Civil Servants (executes and clerks) for 1949 Only established men were included

The "populations" were calculated from special counts as on April 1, 1949, and April 1, 1950

from that in their drivers, moreover, the experience of the two groups of conductors is similar, as is that of the two groups of drivers

Their Interest

What we are looking for, mainly, are useful hypotheses on the causes of coronary heart disease The present observations suggest that in the experience of these conductors and drivers there are real differences which are not due to faulty data or small numbers Here then is a "way in" to the exploration of possible causes Three explanations that might lie behind the differences in incidence and mortality at once come to mind

1 That they are due to differences in the *constitution* and early experience of the conductors and drivers, another expression of which is that the men select for themselves these very different jobs

2 That while there may be *mental strains* in both driving and conducting, these may be of different kinds and the difference may be a factor in the higher incidence and mortality among the drivers

3 That the greater *physical activity* of "conducting" (on these double decker vehicles) is a cause of the lower incidence and mortality in the conductors

It is easy to imagine *all* of these influences contributing to the difference of experience observed (and there may be many more) It is interesting, however, that, so far as the one year's experience goes, the Underground railwaymen (table II) had a pattern of disease similar to that of the road-vehicle drivers The most obvious way in which these railway workers resemble the drivers and differ from the conductors is in the degree of physical activity involved on the job This last proposition—that the physical effort in the conductors' work may be a protective factor, safeguarding them in middle age from some of the worst manifestations of coronary heart disease suffered by less active workers—attracts us most, because it offers special opportunities for study We therefore decided to focus on it for a start, and to ignore the other factors in the constitution of the men and in their history that must certainly also be involved We were further persuaded to do so by a parallel investigation which was made in the Post Office and Civil Service, the results of which became available soon after those of the transport workers

Postal Workers and Civil Servants

During 1949–50 the Treasury Medical Service also ascertaining cases of coronary heart-disease reporting them to the unit Their procedure was follows

Men aged 35–59 years in particular were studied (b of the frequent retirement after 60) and the inquiry limited to "established" personnel, the "population" which was specially enumerated from the Central Staff P by the Organisation and Methods Division of the T Male postal workers in the following grades were incl

Postmen.
Postmen higher grade
Postal and telegraph officers
Supervisors
Telephonists

In addition, established men in the executive and grades of most of the Ministries served by the T Medical Service (i e, most of what is usually termed t Service) were observed The postal workers are in the trar General's social class III, the executive officers in and the clerical grades in both II and III

All sickness absences ascribed to coronary heart- related conditions, or to conditions which were

χ^2 = 16 27 0 001 < P < 0 01 testing the difference between the t groups of workers in the distribution of the number of among the three types of incidence abels" for coronary heart-disease were collected by special rrangement at headquarters in Whitehall and the General ost Office. Treasury Medical Staff scrutinised and checked he diagnoses by correspondence with hospitals and with men's private practitioners and where possible by personal bservation In two-thirds of the cases there was also record f confirmation of diagnosis by a specialist or a hospital pecial arrangements were made with establishment officers or the reporting of all deaths, in particular those occurring ithout preceding sickness absence and copies of all death ertificates were examined The relevant cases and deaths rom coronary heart-disease, presumably related to atheroma, s well as doubtful cases, were then notified by the reasury Medical Service to the unit

able v amalgamates the available data. There were 37 "first episodes" of coronary heart-disease in a 'population' of about 110 000 men most of whom were tudied for two years, making approximately 180 000 man years of observation The incidence of angina rises o 1 2 per 1000 at 55–59 years of age, of early mortality i.e., of those dying in the first three months) to 2·0 he total incidence to 4 9 per 1000 About a quarter f the cases presented as angina, about 40% died in the rst three months of the clinical disease

Tabulation of this data was not begun until analysis f the figures from London Transport was advanced, nd we were therefore most interested to see whether he *experience of the transport workers was repeated* ostmen alone of the seven grades have a physically ctive job though this is not particularly strenuous, hether *judged by the degree of physical activity* mostly walking with a variable amount of stair climbing ycling and light carrying) or its duration (perhaps a hird of the postmen s duties are in the preparation and orting of mail and parcels and this proportion was reater before the Postman Higher Grade was introuced in 1946)( ) There is the further complication hat all postmen higher grade have been postmen, as ave many of the supervisors However there is no oubt that the physical exertion at work of the postman greater than that of any of the other grades included nd there are three truly sedentary grades for comparison -telephonists, executives and clerks. The three parts f table vi thus represent three descending degrees of hysical activity at work the postmen are the most ctive the telephonists, executives and clerks are edentary; the other three postal grades are *less active* han the postmen and, as they are on their feet much or ost of the time, can be considered intermediate in espect of physical activity between the postmen and the edentary group

The results (table vi) show that the total incidence of oronary heart-disease is *lower in the postmen* than in he sedentary grades. Their case fatality is also lower— third in the postmen (57 of 171) compared with almost half in the telephonists, executives, and clerks (70 of 43) Again, therefore as with the transport workers, he early mortality of the physically active group (0 6) substantially less than that of the physically inactive 1 2 per 1000) On the other hand the incidence of ngina is higher in the postmen than in the sedentary orkers (0·7 against 0 5) These differences between he postmen and the sedentary group obtain for each the three constituent sedentary grades individually each of the three mortality is higher than among the ostmen and the incidence of angina is lower and here is a fairly consistent pattern in each age group The postal grades which are 'intermediate' in respect of physical activity show total incidence and early mortality rates that lie, on the whole, between those of the postmen and the sedentary grades.

The experience of the postal workers and Civil Servants may therefore be said to resemble that of the transport workers the physically active group (the postmen) have rather less coronary heart disease, and what disease they do have is less severe There is a greater tendency for the non fatal cases among the physically active group to take the form of angina pectoris (or to be labelled thus) so that once again as in the London Transport survey the incidence of angina in the active men is higher than in the physically less active men The frequency of the diagnosis of angina is particularly interesting for this survey was on a countrywide basis and involved large numbers of practitioners.

Possible psychological explanations again readily come to mind for these variations in coronary experience, though it is difficult to think of mental stress *common* to clerks, executives, and telephonists, yet absent from the others However that may be, we felt that the main interest of these findings in postal workers and Civil Servants lies in the support they provide for the idea suggested by the observation of the transport workers—that physical activity at work is important in relation to the coronary heart-disease of middle aged men

The following account of whooping-cough in young children is derived from five years study of infective respiratory disease in a thousand socially representative families with infants and young children in Newcastle upon Tyne

The justification for a fresh description of such a common disease lies in the difficulty of its early recognition especially in the first week of the illness when infectivity is high and the need to isolate the infected child from other susceptible children is urgent The difficulty is not openly recognised and will be increased greatly in the future by the modifying effects of widespread preventive vaccination

The diagnosis of whooping-cough still rests in most instances on clinical judgment Pernasal swabbing is unlikely to become an acceptable procedure in domestic practice and even in the expert inquiry by the Medical Research Council (1951) bacteriological proof was achieved in only 58% of the cases diagnosed as whooping cough. For these reasons we first describe whooping-cough emphasising those features which should arouse the earliest suspicion of its presence we next describe its behaviour in 388 children in 1947–52 and finally we consider the validity of our definition and the level of diagnostic accuracy which can be expected from a clinical assessment of whooping-cough

---

a) Later in this paper "postmen and sorters are classed for the years 1930–32 as light workers, in comparison with coalminers, for instance and various labourers and craftsmen In the present context the emphasis is on the *relatively* greater physical activity in the work of postmen, compared with the other grades in the Post Office and Civil Service and in particular with truly sedentary workers such as clerks.

Clinical Picture

In most children the first symptom of whooping-cough is a cough For the first few days this is short and "tickly," causing no distress to the child and arousing no suspicion in the minds of the parents The apparent innocence of the early cough is supported by the presence in many children of a nasal discharge, and it is simply regarded as the start of a "cold." In almost half the cases, however, there is no nasal discharge at all. The nasal discharge, once developed, remains watery or mucoid, and tends to wane as the child enters the second week of whooping-cough, whereas the cough, which has grown imperceptibly more pronounced, changes it now comes in bursts or paroxysms In "bronchitis" the child feels the need to cough and takes a breath in anticipation, whereas in whooping-cough he is taken unawares, his chest tightens, and the air is expelled in a sharp rapid stutter

As the second week moves on into the third, the cough increases in speed and rises in pitch, and the paroxysms grow longer and more intense During the paroxysm each inspiration is preceded by a rapid succession of expiratory hacks The child goes red or even blue in the face, the eyes water, saliva and mucus drool from the mouth, and the repeated spasms may end in a strident whoop To complete the distress, many of these episodes are associated with the vomiting of ropy mucus or recent food In a few children the burst of coughing is either replaced or followed by violent and persisting sneezing The spasms often appear to be more severe, and are sometimes more frequent, during the night During the day they are often initiated by excitement or anger, feeding or activity The congestion of the face may be so intense as to cause conjunctival hæmorrhage and epistaxis

In spite of the severity of the cough the general disturbance of the child's health is surprisingly small Although sometimes there is a sharp loss in weight and occasionally frightening emaciation, most of the children simply become indifferent to food and lose a little weight for a week or so at the height of the disease

The dramatic nature of the cough is in striking contrast to the lack of physical signs in the chest In the first two weeks signs are often completely absent, and even at the height of the disease may be limited to a few basal rhonchi In a minority there is a striking bronchitis, and where there is lobular or segmental collapse of the lung, râles will also be present Wheezing is notably absent at all stages of whooping-cough even in asthmatic children Though the bowels may open at the height of a paroxysm, diarrhœa is rare, even in infants, and then it is usually associated with diarrhœal illness in the family or intercurrent infection in the affected child

Gradually, between the fourth and eighth weeks, the coughing spasms grow less, vomiting ceases, and the cough loses its violence and then reluctantly takes its leave However, for weeks or even months after the illness, the cough associated with fresh respiratory infection may closely resemble whooping-cough, although there is no true return of the disease

This, in essence, is the traditional picture We have described it afresh because we have found that the pattern is constant and can be recognised in almost every case There is, however, a wide variation in the tempo of whooping cough and in the intensity of the symptoms, even within the same family We find that the severity is most efficiently assessed not by a count of the daily paroxysms alone but by close attention to the whole clinical picture Where the spasms are few, vomiting occasional, whooping absent, and the constitutional disturbance slight we regard the child as mildly affected, where the paroxysms are many and violent, with frequent vomiting and whooping and loss of appetite, weight, and zest we regard the child as severely affected The group between these two extremes we consider of "moderate" severity Yet, in spite of these variations in degree, the distinctive pattern and movement of the illness can be recognised in the mild as in the severe

Diagnosis

The clinical constancy of whooping cough will permit a clinical diagnosis to be reached in most cases. If we remember to ask, a history of contact is forthcoming in about half the children, and any cough occurring in an exposed susceptible child from ten to sixteen days after exposure should be regarded as whooping-cough until the natural history of the ensuing illness proves the assumption to be wrong

The main problem in diagnosis lies in the separation of early whooping cough before the characteristic cough has developed and whooping-cough which remains mild throughout, from the varied assortment of colds and coughs which are so common in childhood

The condition most likely to be mistaken for whooping cough is the severe cold with an irritating postnasal discharge The discharge in a severe cold is not thin and watery but generally thick and purulent, often with nasal obstruction, sniffing, and snoring The cough, too, is more noisy than early whooping cough, and comes on particularly at night after first going to bed and on rising in the morning It is a booming or barking cough, and though it may last for several weeks it does not change its character or progressively increase its speed and intensity

The next problem in diagnosis is to distinguish whooping-cough from that group of diseases covered by the broad label of "bronchitis" In our experience bronchitis presents in three main ways as an extension of the severe cold which we call "coryzal bronchitis" as a sharp respiratory illness, an "acute bronchitis" with constitutional upset and widespread rhonchi in the chest, and as respiratory illness dominated by wheezing which we call "wheezy bronchitis" The last category will naturally include children who have asthma, but most wheezy bronchitis is probably infective

With careful attention to the cough, the physical signs in the chest, and the progress of the disease in the first ten days, the separation of these three conditions from whooping-cough is not difficult When a severe cold goes on to a coryzal bronchitis, the cough often becomes loose or rattling but does not increase in speed and is not associated with choking or with vomiting The chest will be full of rhonchi, in contrast to the pulmonary silence so characteristic of the early days of whooping cough

Acute bronchitis is quite a different illness, with a sudden onset and a rapid tempo A watery nasal discharge may precede the cough but rarely for more than twenty-four hours With this mild rhinitis there is sometimes a sore throat, and the voice may be hoarse The cough is generally hard and barking In the infant and younger child wheezing is not uncommon, and this in itself is sufficient to exclude whooping-cough Although vomiting at the onset of acute respiratory illness is common continued vomiting is unusual—a fact which is true for almost all respiratory diseases apart from whooping cough

The disturbance of general health in acute bronchitis develops rapidly and is at its height towards the end of the first week The whole illness is generally over within two or three weeks

Since wheezing is so unusual in whooping-cough, the distinction between it and wheezy bronchitis presents little difficulty

As the characteristic cough of whooping-cough develops, the idea of a foreign body in the bronchi or of primary lung tuberculosis may arise These mportant conditions however are rarely mistaken for whooping-cough and their special features will not be lescribed here.

A distinction between pertussis and parapertussis is mpossible without bacteriological help Though parapertussis can present as a mild whooping-cough, it may produce no more than a modest cold and cough or bronchitis lasting less than a month However it forms a small and unimportant part of the total picture of whooping-cough and need be considered only when second clinical attacks of whooping-cough occur in the same child.

Epidemiology and Character of Whooping cough in Newcastle upon Tyne

Amid the bewildering variety of respiratory diseases we have accepted as whooping-cough any illness in which the child developed a rapid spasmodic choking cough generally associated at some stage with vomiting and less often with whooping and lasting for a month or more. Since symptomless carriers are almost unknown this clinical definition can be completed for the small atypical minority by accepting in addition any respiratory illness in which *Hæmophilus pertussis* can be isolated from either the respiratory tract or its discharges

On the basis of this definition 388 (43%) of 906 children studied from birth until either their 5th birthday or their death had whooping-cough, and 97 (11%) had whooping-cough before they were a year old Whooping cough is most dangerous, though not always severe, in infancy The 6 children with pneumonia and the 3 with fatal whooping-cough were all infants and there were no deaths after the first year The main features of whooping cough in infancy were as follows :

		No of cases (%)
Cough		100
Vomiting		74
Whooping	55	93
Choking alone	38	
Nasal discharge		49
Anorexia		45
Loss of rest		43
Diarrhoea		
Pneumonia		6
Death		3

There were additional features affecting the group as whole which will now be mentioned because they bear directly on the recognition of whooping-cough Fig 1 shows that unlike measles, whooping-cough was continuously present throughout the five years without epidemic peaks. For the doctors of Newcastle there were no close seasons, and they could expect to meet whooping cough at any time Again, there was no exemption for the young infant The first affected child was only 14 days old, and 5% of the whole group had started whooping cough before they were 6 months old Fig 2 shows the steady progress of whooping-cough through these 906 children year by year

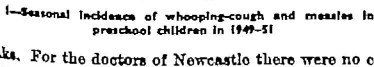

Fig 1—Seasonal incidence of whooping-cough and measles in 906 preschool children in 1949–51

Again the source of the whooping-cough was known or strongly suspected in more than half the children and inquiry for a history of contact is a valuable and, we suspect, often neglected procedure

When contact took place within the family circle, infectivity was high, 8 out of every 10 of the survey children who were susceptible contracting whooping cough In 18 families the whooping cough also spread to one or other of the parents, producing a mild or moderate attack, and 3 mothers appeared to be the first affected members of the household

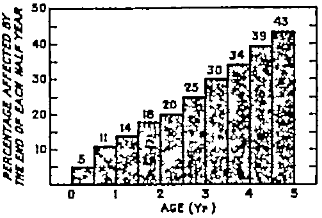

Fig 2—Progression of whooping-cough through 906 preschool children in 1947–52.

Discussion

We have described whooping cough as we have seen it in 388 young children and their families The clinical concept of whooping cough that grew out of our total experience of respiratory illness in the 906 families and led to our accepting these 388 and rejecting others has already been defined

We must now consider the reliability of our definition —how far we have included children who really had colds or bronchitis and how far we have excluded atypical examples of genuine whooping-cough. The level of diagnostic accuracy which can be expected in a clinical survey of this kind is so important that we shall set down the reasons why we regard our definition of whooping cough as essentially reliable

In 278 (72%) of the affected children there was confirmatory evidence from known contacts or from secondary cases developing within the family

Again, among the 388 children only 4 had a second attack during the five years Let us suppose that in a substantial proportion of our accepted cases the diagnosis was false and they had some clinically similar respiratory disease which gave no immunity If we take the extreme view that none were correctly diagnosed, the number of children with one, two or more attacks would approximately follow a predictable distribution In our total group of children the number of colds experienced in the first year of life did follow this type of distribution very closely ; and if this applied to the children with whooping-cough we should have expected not 4 but 98 second attacks, together with 17 third or later attacks

We have naturally considered the children with double attacks with great care If we assume that these were due to infection by *H parapertussis* the minimal incidence of that disease in our total picture of whooping cough was 1% which is almost the figure found in the Medical Research Council's (1951) investigation As regards the lower limit of true incidence, therefore we feel confident that we have not overestimated the figure

But we are still faced with the possibility that whooping-cough is not a consistent disease, and that by definition we have been seeing only the centre of a clinical spectrum and missed a wide marginal band of atypical cases. Our reluctance to attempt intensive bacteriological investigation over a wide range of respiratory disease does not allow us to give a bacteriological answer to this important question. Some help on this point however was given in the course of the Medical Research Council's (1951) inquiry Dr W C Cockburn (personal communication) and his colleagues found that, in 836 children who developed clinical whooping-cough, *H pertussis* was recovered from the nasopharynx in 58%, whereas in 380 children who were exposed to whooping-cough and developed a non paroxysmal cough from 7 to 42 days afterwards the organism was recovered from some 5% Since this was a group of children in which we would expect to find the atypical cases of pertussis, the marginal fringe throughout the general child population must be very small 388 (43% of our total group) had therefore experienced a disease which we feel sure was whooping-cough by their fifth birthday

Comparisons with the notifications of whooping-cough in Newcastle over the same period are interesting From 1947 to 1951 there were 3624 notifications in an estimated average population of 24,500 children aged less than 5 years This means a notified incidence in the preschool child of 15%, or a third the observed incidence in our representative group There are several possible reasons for this discrepancy only three quarters of our children with whooping-cough saw their family doctor, the doctor, having recognised the disease, does not always notify it, and in some cases the doctor does not recognise the whooping cough and calls the case one of bronchitis We have no exact information of the relative importance of these three factors, but we feel sure that failure of recognition is not the least important

Summary

The present character of whooping-cough in a representative group of families with young children is described

In five years 388 (43%) of 906 preschool children developed whooping cough

Family infectivity was high, and whooping cough followed in 8 out of every 10 susceptible children exposed within the family circle

Although the tempo and severity vary considerably, a constant pattern of illness is present in the great majority of cases, and whooping cough can be strongly suspected in many of these in the first ten days

In this article we are speaking as members of a group of doctors, health visitors, and secretaries engaged in the study of illness in young children This inquiry is directed by Sir James Spence, Dr F J W Miller, and Dr Stanley Walton, the medical officer of health We wish to thank all who shared in this work.

Counter irritation is perhaps the oldest of all methods used for relieving pain The physiological mechanisms responsible for this action have never been satisfactorily defined, but they are discussed in many of the standard works on pharmacology (Poulsson 1938, Goodman and Gilman 1941, Douthwaite 1952, Wilson and Schild 1952) Most workers make a distinction between rubefacients, which cause cutaneous vasodilatation by an axon reflex, and counter irritants proper, which stimulate the sensory nerve endings and produce burning pain. It is well known, however, that the effects depend largely on the concentration of the medicaments · a strong preparation of a rubefacient can cause considerable irritation, and powerful counter-irritants are rarely free from some vasodilator action Irritation often develops within a few minutes, whereas vasodilatation may become conspicuous only after $^1/_2$–1 hour In recent years synthesis of several esters of nicotinic acid has m available a new group of drugs which cause vasodilatat when applied to the skin Their effects probably depe on rapid absorption and a direct action on the blo vessels of the skin These are now in common use counter irritants, either alone or in combination w other substances such as menthol, camphor, and capsi

We report here a simple experimental method assessing the effects of rubefacients and counter irrita especially for determining the efficacy of the esters nicotinic acid in the relief of pain

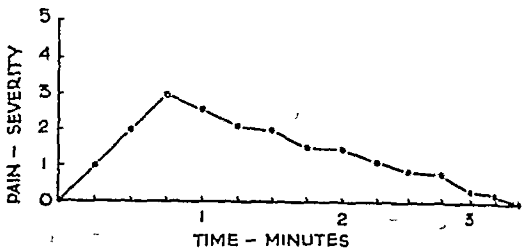

Fig 1—Production of pain with intramuscular saline solution in J. G. (composite graph made from 28 graphs)

Production of Pain

We produced pain of predictable severity and durat by injecting one another intramuscularly with hyperto saline solution The technique has been used by oth

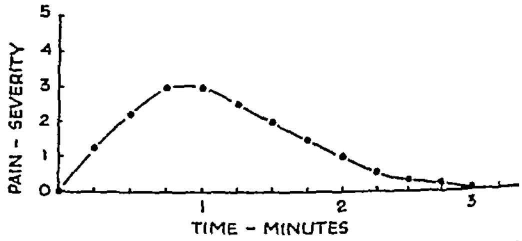

Fig 2—Production of pain with intramuscular saline solution in S (composite graph made from 30 graphs)

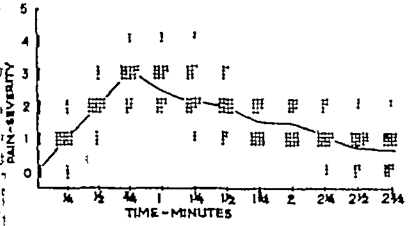
especially Lewis (1938) and Kellgren (1949), who re nised its advantages in experimental work becau leads to "a continuous pain which resembles more clo the pain of disease than does the momentary produced by exploration with needles" The techn is therefore different from that of previous workers have studied ischaemic muscle pain (Hower and K 1948) The site selected for the injections was the mu belly of the brachioradialis $2^1/_2$–3 in below the exte epicondyle of the humerus This produced aching p which was most intense at the site of injection but so times radiated down the extensor aspect of the fore as far as the wrist The aching increased in severity the first minute and then diminished progressively had usually disappeared after about three minu While the severity of the pain was being recor movement of the arm was avoided

The earlier tests were made with 6% saline It thought, however, that the pain caused by this con tration might be too severe to be relieved by coun irritants used therapeutically Accordingly experim were made to determine the minimal effective concen tion—i e, the one which would cause pain which relatively mild but nevertheless adequate for recor and constant enough in intensity and duration critical concentration was discovered at 2 75% fo dose of 0 2 ml Solutions only slightly weaker (2 caused negligible discomfort The pain response recorded every 15 seconds An arbitrary system numerals—1, 2, 3, 4—was used to represent increa



g. 3—Production of pain with intramuscular saline solution in J G M (scatter diagram)

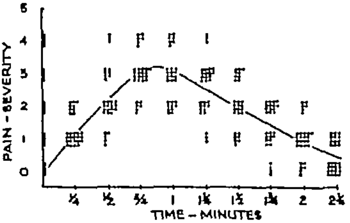


Fig 4—Production of pain with intramuscular saline solution in S.A. (scatter diagram)

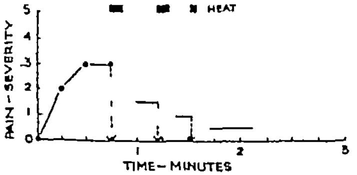
verity These numbers have no absolute significance hey provide a useful method for recording a substantial hange—increase or decrease—in a pain characterised y fairly rapid onset and relatively slow deferrvescence sing hypertonic saline as described above an observer oon learns to recognise a pain response which is close o the mean and others which deviate from this But the easurement of pain is necessarily a procedure in which o-one can share; hence it cannot be assumed that the bitrary assessments of pain are transferable from one bserver to another—even under the standard conditions f this experiment The similarity of the control curves f the two observers in the present investigation is herefore a matter of little importance The pattern of hese records (figs 1–4) was sufficiently consistent for ach observer In this investigation upwards of 200 njections of hypertonic saline were given On 4 occasions ne of us (S A) experienced no pain following the njection. It is difficult to account for this exceptional ccurrence, but it may have been due to the placing of he saline solution in an insensitive zone of muscle or—hough this is less likely—in a small vein When another njection was given a few minutes after these failures,' ching pain of the usual intensity was felt in the forearm

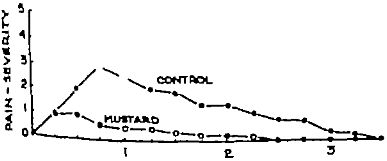


g. 5—Radiant heat as counter-irritant (J G M 16 tests S. A. 13 tests no failures)

Physical Counter Irritants

As a preliminary to studying the effects of chemical ritants applied to the skin in ointments, an attempt was ade to produce counter irritation with radiant heat nd with continuous galvanism.

Radiant Heat.—As a control test saline solution 2 75%) was injected into the brachioradialis muscle of one arm and the resulting pain was recorded. After 10–15 minutes a similar injection was made into the other arm and immediately the forearm—especially the extensor surface—was held close to an electric radiator so that fairly severe burning pain was felt in the skin The result was that the aching pain from the intramuscular injection of saline was completely abolished. The number of tests made was 29 and the same result was invariably obtained (fig 5) It was also found that if the injection of saline solution was made into one forearm and the other arm was simultaneously exposed to strong radiant heat the severity of the aching pain was greatly relieved but not entirely abolished.



g. 7—Volatile oil of mustard as counter-irritant in J G M (composite graphs from 21 consecutive tests and 28 controls)

Continuous Galvanism.—The procedure here was similar to that adopted to test the effect of radiant heat. The indifferent electrode was placed on one arm An injection of 2 75% saline solution was then made into the other brachioradialis muscle and the exploring electrode immediately placed over the belly of the muscle. When the aching pain had developed, galvanic stimulation was rapidly increased to 30 mA This produced in the skin severe irritation burning in quality and only just tolerable, which completely replaced the aching sensation arising from the saline solution (fig 6)

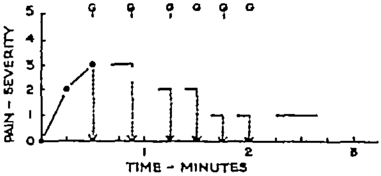


Fig 6—Galvanism as counter-irritant (J G M 17 tests S. A. 5 tests)

Chemical Counter Irritants

The two further series of tests recorded below were made to determine the value of a skin irritant (volatile oil of mustard) and a vasodilator (an ester of nicotinic acid) in relieving muscle pain induced by saline solution

Mustard—The preparation used was 3% volatile oil

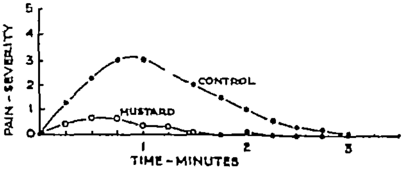

Fig 8—Volatile oil of mustard as counter-irritant in S. A. (composite graphs from 21 consecutive tests and 30 controls)

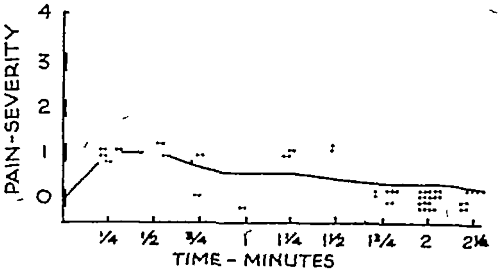

Fig 9—Volatile oil of mustard as counter-irritant in J G M (scatter diagram)

of mustard in simple ointment (*B.P*) A preliminary control test was made by injecting saline solution into one arm as described above, and the intensity and duration of the pain were recorded as previously described The other arm was then prepared by liberal application of the mustard ointment from the wrist to about 2 in above the level of the elbow-joint After about 20 minutes the skin irritation was intense, and was judged to be about as severe as any normal person would be prepared to tolerate Vasodilatation developed slowly at the site of application, but the flushing of the skin was much less intense than that produced by the nicotinates applied locally (see below) At this stage an injection of 2 75% saline was made in the usual way Each observer carried out this procedure on 21 occasions, and the results are shown in figs 7–10 It will be seen that, in the presence of skin pain induced by oil of mustard, much lower levels of deep pain were experienced following intramuscular injections of hypertonic saline

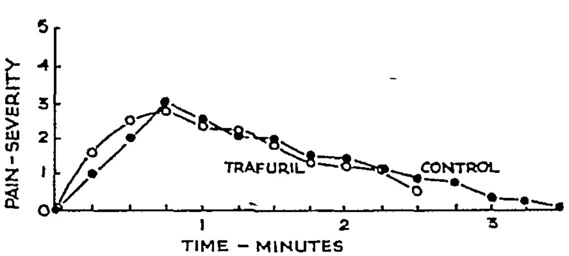

Fig 11—Trafuril as counter-irritant in J G M (composite graphs from 21 consecutive tests and 28 controls)

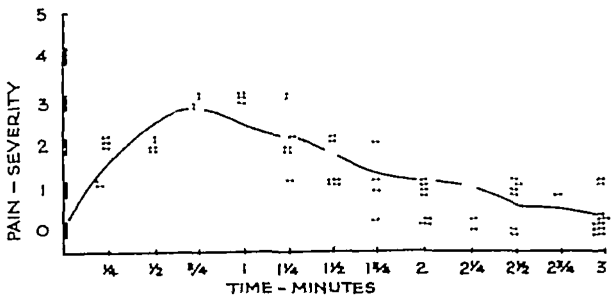

Fig 13—Trafuril as counter irritant in J G M (scatter diagram)

Ester of Nicotinic Acid—When 5% tetrahydrofurfuryl nicotinic acid ('Trafuril') is applied to the skin of the forearm, vasodilatation begins after about 5 minutes and becomes intense in about 20 minutes The flushing of the skin is accompanied by a feeling of warmth and occasionally slight pricking

The same procedure used in testing the effect of volatile oil of mustard was adopted to assess the pain relieving action of trafuril The results are shown in figs 11–14 It is clear that, despite intense vasodilatation in the overlying skin, the severity of saline induced muscle pain was not materially affected.

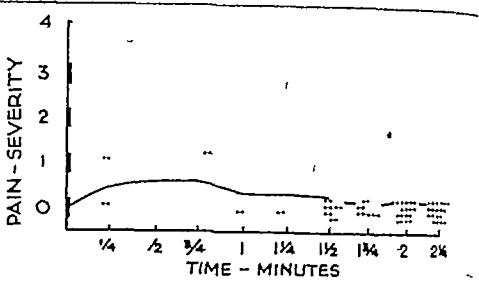

Fig 10—Volatile oil of mustard as counter-irritant in S. A. (sc diagram)

Summary

Hypertonic saline solution injected intramuscul produces deep aching pain Under standard condit the intensity and duration of this pain are const enough to provide a method for assessing the value counter irritants

The phenomenon of counter irritation can be conve ently demonstrated by means of radiant heat or by galva stimulation strong enough to produce severe skin pain

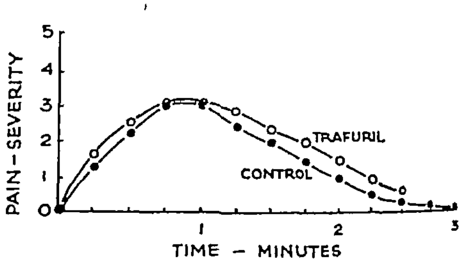

Fig 12—Trafuril as counter-irritant in S A (composite graphs fro consecutive tests and 30 controls)

Volatile oil of mustard (3% in simple ointment), wh causes moderately severe irritation when applied to skin, is very effective in relieving saline induced p Esters of nicotinic acid, in concentrations sufficient cause intense flushing of the skin, are relatively ineffecti

It is concluded that, under these experimental co tions, the relief of deep seated pain by counter irrita depends on the *production* of skin pain of adequ intensity, and that cutaneous vasodilatation is un portant

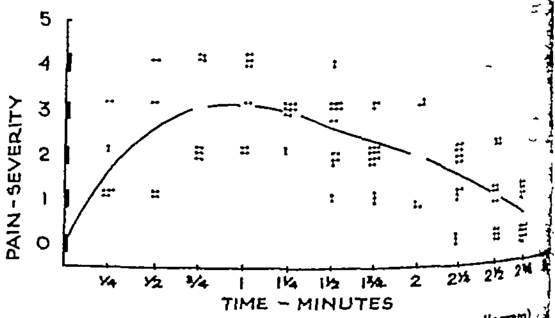

Fig 14—Trafuril as counter-irritant in S A. (scatter diagram)

We wish to thank Miss M Blue, of the physiother department, and Mr D W Blackwood, senior pharma for their assistance, and Mr R Callander for the diagram

CONTROL OF VOMITING IN CHOLERA
AND ORAL REPLACEMENT OF FLUID

HEMENDRA NATH CHATTERJEE
M.D. M.S. B.A.

SENIOR VISITING PHYSICIAN, CHOLERA WARD
CHITTARANJAN HOSPITAL, CALCUTTA

VOMITING is a major alimentary symptom in cholera second only to diarrhœa in this respect It may be present either from the onset of the illness or may start later when the patient is recovering from dehydration after intravenous transfusions Vomiting was present in 40% of our cases of the 1953 epidemic (437 out of 1093 cases)

The usual remnants of the stomach contents come out at first but subsequently the vomitus is entirely watery The act of vomiting is distressful and noisy and quickly leads to exhaustion and shock

AVOMINE THERAPY

In 59 cases of cholera in the latter part of the 1952 epidemic and in 127 cases during the 1953 epidemic I treated vomiting with tablets containing 'Avomine' 25 mg (14 mg of promethazine base and 11 mg of 8-chlorotheophylline in chemical combination) During the same period 907 cases of cholera were treated without avomine, making a total of 1093

In the mild cases vomiting was often checked with a single tablet. When, however it continued further tablets were given The largest number of tablets found necessary was six in twenty four hours in 1 case The patients to whom it was given were a selected group whose condition was relatively satisfactory but it is noteworthy that there was not a single case among them in which vomiting was not ultimately controlled with avomine. Nor have I observed any toxic or untoward effects with the doses mentioned

The vomiting and the distress it causes are described by Sir Leonard Rogers (1921) thus

> the vomiting of much watery fluid when but little has been swallowed is one of the pathognomonic features of cholera. When very copious it does much to exhaust the patient and may be an important factor in producing collapse On account of the terrible thirst the patient calls repeatedly for water only to reject it almost at once together with any medicine which may have been given. Nothing however is more cruel than to withhold water from those in the throes of cholera

The doctor who sees a cholera patient is often confronted with a dilemma. If he allows water even in small quantities the patient will usually throw it up immediately and the dehydration and shock will increase, thus setting up a vicious circle. If on the other hand the doctor withholds water from a patient with extreme thirst—a distressing thing to do—the dehydration and shock may again be increased. After the administration of avomine however there has been no necessity of withholding water which could be given in any quantity desired.

NUMBER OF AVOMINE TABLETS WHICH RELIEVED VOMITING IN 100 CASES

No. of tablets needed to stop vomiting completely	1	2	3	4	5	6
No. of cases	41	30	18	7	3	1

The numbers of tablets required to relieve vomiting in 100 carefully observed cases of cholera accompanied by vomiting are given in the accompanying table These cases were observed between April 5 1953 and June 25 1953, the seasonal peak of the cholera epidemic

All these patients had agglutinable cholera vibrios in their stools on culture The stool specimens were collected in each case in a sterile test-tube after a boiled no 10 catheter had been passed into the rectum The cultures were made usually within fifteen minutes of collection, on the following three different culture media on separate plates: MacConkey taurocholate agar and D.R.C (Panja and Ghosh 1943)

REHYDRATION

The control of vomiting with avomine makes it possible to relieve the cholera patient's extreme thirst to replace water and electrolytes by mouth and to prevent the loss of body fluid in the vomitus Avomine, however does not check choleraic diarrhœa, and for this purpose I use the juice of the raw leaf of *Coleus aromaticus* an Indian plant (Chatterjee 1953)

When vomiting and diarrhœa have been substantially controlled with these two agents we have found it possible, in the mild cases, to restore the lost fluids and electrolytes by mouth alone, enabling these patients to tide over the condition to convalescence We classified as mild those cases with blood sp gr 1·062 or less and a good pulse there were 33 such cases. In moderately severe cases with blood sp gr 1·062–1·064 administration of fluid by mouth and per rectum was necessary: there were 153 such cases. The fluid used in my ward for both routes was composed as follows:

Sodium chloride 4 g
Glucose, 25 g
Water ad 1000 ml.

After a free flow of urine had been established potassium chloride 2 g was added to each litre of fluid

DISCUSSION

Of 1093 patients 33 with mild cholera were tided over to convalescence by the administration of fluid by mouth alone and 153 patients with moderately severe cholera were cured by the administration of fluid by mouth and per rectum making a total of 186 cases (17% of all the patients treated) in which intravenous or parenteral administration of fluid was unnecessary All 186 patients were discharged clinically cured

A substantial majority of cholera patients are brought to the hospital with advanced dehydration and shock requiring intravenous transfusion therapy But it is possible that if full use were made of avomine to prevent vomiting many of these cases could be saved from drifting into this advanced stage of dehydration and shock The proportion treated without intravenous therapy might well be higher than 17% In our series, as has been explained, avomine was given only to the 186 cases (17% of the total) who seemed likely to benefit

SUMMARY

Vomiting in cholera leads to dehydration and shock

In 59 cases in the 1952 epidemic and in 127 cases in the 1953 epidemic vomiting was treated with avomine Of these 186 cases 33 were mild and 153 moderately severe All these patients recovered

Avomine does not stop the diarrhœa For this purpose the leaf juice of an Indian plant, *Coleus aromaticus* was used.

The combination of these two remedies enabled patients with mild or moderately severe cholera (blood sp gr up to 1·064) to achieve convalescence without intravenous or parenteral transfusions

I offer my heartfelt gratitude to the memory of the late Dr Shyama Prosad Mookherjee who was very keenly interested in our work and I wish also to thank Dr Debi Kumar Bose and Dr Priya Ranjan Chakravarty of the laboratory section and Dr Robi Shaha, of the clinical section of the cholera ward, for their coöperation Messrs. May & Baker supplied the avomine and partly financed this research

DUPUYTREN'S CONTRACTURE

A RADIOTHERAPEUTIC APPROACH

R FINNEY

M B Lond , F R C S.E , D M R T

ASSISTANT RADIOTHERAPIST, ST THOMAS'S HOSPITAL, LONDON ,
FORMERLY REGISTRAR, LIVERPOOL RADIUM INSTITUTE

Dupuytren's contracture, if left untreated, slowly progresses with an increasing flexion deformity of one or more fingers and accompanying increasing functional disability During the last fifty years many different methods of treatment have been employed, including injections of lysins, electrotherapy, physiotherapy, and psychotherapy, which have all been in vogue from time to time More recently treatment with vitamin E has been introduced, but with somewhat equivocal results, and the treatment of choice has remained primarily by surgery

Treatment by ionising radiations has received but little following, and only the Radiumhemmet in Stockholm (Skoog 1948), and Slanina (1948) in Germany, report on its use in any considerable number of cases

Histopathological Changes

Although Dupuytren's contracture remains of unknown ætiology, much work has been done on the histopathological changes which accompany it, especially by Meyerding et al (1941) and by Skoog (1948)

From earliest times the changes in the palmar fascia have been held responsible for the characteristics of Dupuytren's contracture Workers have emphasised that fibrosis and contracture cause the chief manifestations by contracture of the palmar fascia In a detailed study of this subject, however, Meyerding et al (1941) have shown that changes take place not only in the palmar aponeurosis but also in the " extrafascial " tissues, and that the changes in the skin and subcutaneous tissues are as important as those in the palmar fascia

EXTRAFASCIAL CHANGES

The earliest evidence of histological changes is a lymphocytic infiltration combined with an increase in the number of capillaries This begins in the interstitial connective tissue and gradually spreads to all the tissues in the palm This infiltration precedes fibrosis, fat is absorbed or destroyed, and new connective tissue is formed Then, in advanced cases, subcutaneous adipose tissue and sweat glands become rare or absent, and dense parallel strands of fibrous tissue lie beneath the reticular layer of the dermis Hence the skin becomes thickened, puckered, and bound down to the underlying tissues The accompanying photomicrographs illustrate this " inflammatory reaction " in an untreated case, showing the typical perivascular cuffing, lymphocytic infiltration, and aggregations of fibroblasts (figs 1 and 2)

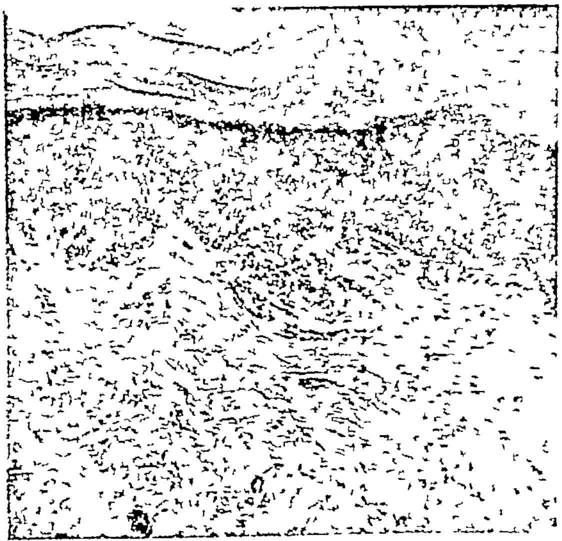

Fig 1—Stage I: nodule in palmar skin of untreated case showing epidermal thickening, with increased vascularity in subepidermal layers aggregations of fibroblasts and perivascular cuffing with lymphocytes and plasma cells (×80)

PALMAR FASCIAL CHANGES

These are entirely different from the extrafascial changes Lymphocytic infiltration, increase in capillaries, and perivascular cuffing are almost entirely lacking. The characteristic change is a proliferation of the fibroblasts in the nodules of the contracture In the earlier immature stages the fibroblasts tend to grow in masses closely packed together A cycle of events then takes place in which there is deposition of collagen fibres, contraction of the collagen, and compression of the fibroblasts, producing an avascular scar tissue and contracture of the fascia

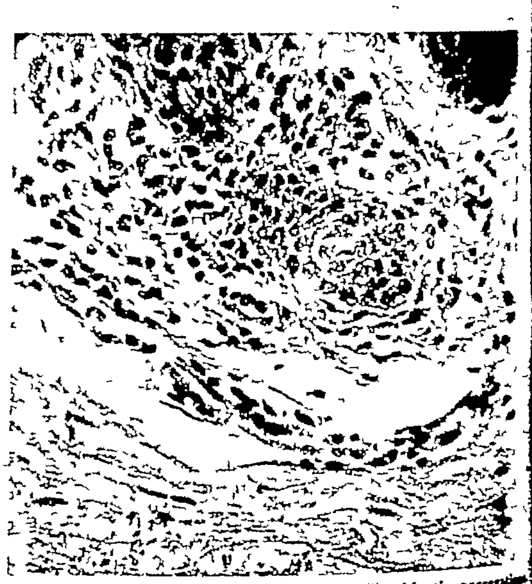

Fig 2—Same section as in fig 1, showing fibroblastic aggregation and lymphocytic infiltration in greater detail (×200).

Skoog (1948) criticises the suggestion that the extrafascial changes are an " inflammatory reaction " and considers that the aponeurosis is the structure where the initial changes occur Furthermore, these changes may become so excessive as to spread beyond the limits of the palmar fascia " in a manner reminiscent of a tumour " This spread progresses diffusely to all parts of the aponeurosis, with the result that changes also take place at the attachment of the aponeurosis to the skin Skoog does agree, however, that in the development of the nodules in the aponeurosis the new formations of connective tissue issue from the perivascular tissue of the adjacent vessels These vessels become dilated, increased in number, and are surrounded by perivascular sheaths of fibroblasts, leucocytes, and round cells, especially in the more mature areas where the round cells predominate

The hypothesis of Meyerding et al (1941) that the skin changes follow an " inflammatory reaction " seems to satisfy the clinical findings of skin thickening, puckering, and nodularity over a wide area of the palm rather than only at the site of skin attachment as postulated by Skoog Moreover, it is well known that skin nodularity and thickening may be found before fascial changes become apparent clinically

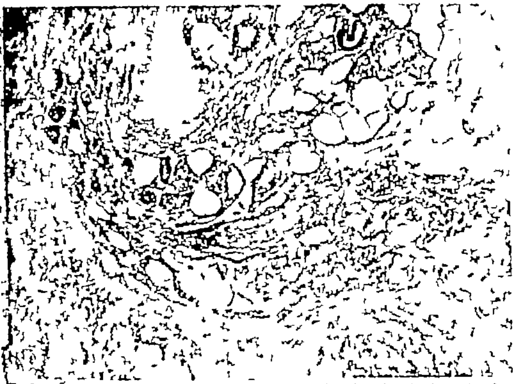

Fig. 3—Stage 3: nodule in palmar skin four months after irradiation showing absence of fibroblastic aggregations and lymphocytic infiltration and no evidence of fat-absorption (×80)

The changes described above can be compared to the changes in scars which become keloid. Glücksmann (1951) has shown that an orderly sequence of events takes place, which he also describes as an "inflammatory reaction." This consists in round-cell infiltration of the subcutaneous tissues, considerable perivascular reaction, and fibrosis—a picture identical with the extrafascial histopathological changes seen in Dupuytren's contracture.

Surgical Treatment

The operation most widely practised today is that based on the lines advocated by Kanavel et al. (1929) consisting of a radical removal of the entire palmar aponeurosis and removal of the affected skin, with skin grafting where necessary. This appears to be satisfactory judged by the early functional results published by various surgeons. However, the recurrence rate following radical surgery is far from negligible.

Reference	*No. of cases*	*Recurrence (%)*
anavel et al. (1929)	39	35
orens (1917–18)	30	33
eyerding et al. (1941)	63	17
avis (1932)	—	30
oss and Annan (1951)	11	10

In view of the histopathological findings described above it is not surprising that the recurrence rate reaches such a high figure, as changes can still proceed in the extrafascial tissues even after the palmar aponeurosis has been excised.

Radiation Treatment

The rationale of treating a condition in which the main emphasis has been on contracture following fibrosis is not at first apparent, but again it is as well to recall the histopathological changes and the close comparison with the similar changes in keloid scar formation. Radiotherapy has been long used in the treatment of keloid and hypertrophic scars, both alone and in conjunction with surgery. According to Levitt (1951) the effect of radiation on the processes leading to the development of the scar appears to be that the round-cell infiltration is reduced or suppressed, probably by direct action. Epidermal fibrosis and proliferation are thus inhibited.

Further, the effect of irradiation on the fibroblasts, as borne out by in-vivo histology and in-vitro experiments, shows that their mitotic cycle can be readily interrupted. The death of the cell will therefore cause a break in the cycle of events so that no further collagen and therefore no further scar tissue will be laid down.

As a result, therefore, of irradiating the whole palm it should be possible theoretically to interrupt the cycle of events producing further contracture. This appears to be borne out both by the accompanying photomicrographs (fig. 3) from cases treated by radiotherapy and by the over-all results.

Staging

In the present series of cases the clinical condition was "staged" according to a modification of the lines advocated by Shaw (1951) as follows:

Stage 1 includes (*a*) hands with a nodule in the palmar fascia not yet including the skin and causing no contracture of the fingers, or (*b*) nodules present in the skin with no apparent changes in the palmar fascia.

Stage 2 comprises a nodule in the fascia involving the skin but not causing finger flexion deformity.

Stage 3 comprises a nodule in the palm invading skin plus flexion contracture of one or more fingers.

Stage 4 includes all stage-3 cases in which the secondary changes have occurred in the tendons or joints of one or more fingers.

Technique

Gamma radiation alone was used in the present series. As the pathological changes may extend throughout the whole of the aponeurotic area the tendency has been to irradiate the whole of this volume of tissue comprising the palmar fascia and adjacent tissues. Two techniques have been used according to the stage of the condition.

In stages 1 and 2, before contracture has

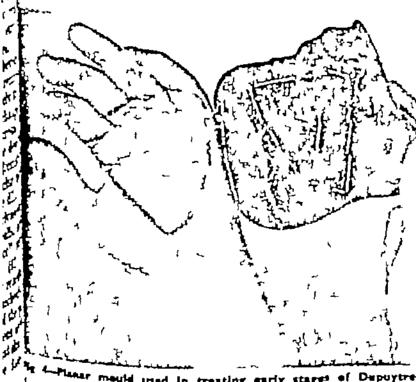

Fig. 4—Planar mould used in treating early stages of Dupuytren's contracture showing area irradiated

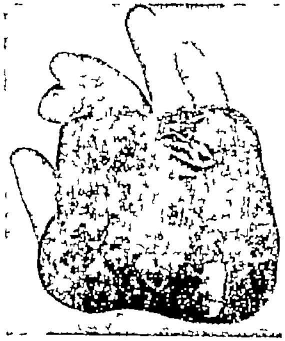

Fig. 5—Planar mould in position for treatment.

occurred, a planar mould is made of Black Tray compound, and the area to be irradiated is mapped out on the mould A treating distance of 1 0 or 1·5 cm is used The mould is illustrated in figs 4 and 5

In stages 3 and 4, when contracture has occurred and a planar mould can no longer be applied, a grip cylinder is made—again of Black Tray compound of a radius of 1 0 or 1 5 cm This is illustrated in fig 6 The total dose of 3000 r to the skin is given in fractional doses of eight hours a day for eight days

Results

The results in 25 cases treated by radium mould technique are given in the accompanying table

In no case did the patient have difficulty in wearing or in retaining the appliance Apart from some skin dryness and occasional slight erythema, no skin reaction was observed in any of the cases thus treated

Subjective improvement—including softening of the nodules, lessening of paræsthesia, and increase in finger movement—were evident within the first four weeks after treatment Objective improvement, gauged by increase in movement, began on an average within 1 7 months and became maximal by 6 0 months There was no improvement after twelve months had elapsed from the time of treatment

The period of follow up was two to ten years Of the 25 cases 75% were improved and 25% remained static Of those cases which improved 25% fully recovered, 25% partially recovered, and 25% were only slightly improved, but in no case was the condition made worse or did the contracture increase after the treatment had been given

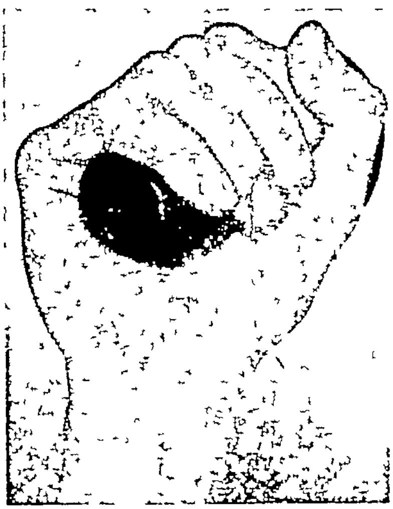

Fig 6—Cylinder or grip mould used when contracture has already taken place.

Those cases in which full recovery occurred belonged to stage 1 or 2, i e , before fibrosis or scar tissue had been laid down

Those cases in which no change, or only moderate improvement, took place belonged to stage 3, when scar tissue had already been laid down and which would only respond to a limited degree, depending on the amount of avascular scar tissue present

These results are confirmed by the findings of Stockholm Radiumhemmet, where, in treating 149 cases, it was found that, although improvement varied considerably, *in all cases the processes were arrested*

The logical approach to the treatment of Dupuytren's contracture appears therefore to be by radiotherapy used either alone or as a preoperative measure If a combined attack be decided on, the functional improvement is allowed to continue until the greatest effect has resulted After this, if functional disability remains, this may be corrected by surgical means Postoperative recurrence will thus be reduced to a minimum

Summary

The results of treating 25 cases of Dupuytren's contracture with radium are reviewed

RESULTS OF TREATING 25 CASES OF DUPUYTREN'S CONTRACTURE BY RADIUM MOULD TECHNIQUE

Average time of greatest improvement 6 0 mos.

+ + +	full functional recovery
+ +	functional improvement but short of return to normality
+	limited improvement only
—	no change

The treatment of Dupuytren's contracture by irradiation can be as successful as radical surgery in curing the condition, especially in the earlier stages of the disease. In the later stages improvement is less evident, but in 25 cases in the present series the progress of the disease was arrested

Recurrence following adequate irradiation of the palm appears to be rare, if it occurs at all

Improvement in contracture is maximal within twelve months following the initial treatment

There therefore seems to be a place for a combination of preoperative irradiation followed by radical surgery in these cases, along the lines used in the treatment of keloid scars In these cases complete excision of the aponeurosis can be undertaken without fear of recurrence

The present cases were all treated at the Liverpool Radium Institute, and I am grateful to the medical director Dr J Fulton, and Dr M A C Cowell for their help and encouragement I should also like to express my thanks to Miss D of the statistical department, and Mr W Braden and Mr M Tillp, of the photographic department

From the Renaissance onward developments in medicine illustrate the extreme difficulty that man has always had when accumulations of facts, the raw data of science, so overload the intellect that logic goes flabby from overwork in systematizing knowledge Imagination is shackled, perhaps by fatigue or by not having the time needed for meditative gestation In any event, we have seen the stringency of the austere rationalism of the Middle Ages and the old urbanity of Greek rationalism fade out before the immense and monolithic aggregations of contemporary fact How truthful were the words of Artemus Ward—'The researches of so many eminent scientific men have thrown so much darkness upon the subject that if they continue their researches we shall soon know nothing' "—Dr W BENNETT BEAN, *Arch intern Med* 1953, 92, 153

PROLONGED APNŒA FOLLOWING INJECTION OF SUCCINYLDICHOLINE

EARCH ASSISTANT ST BARTHOLOMEW'S HOSPITAL, LONDON

SEVERAL cases of prolonged apnœa following injection (the ultra-short-acting relaxant succinyldicholine loride have now been published At first this was tributed to possible synergism with thiopentone arron 1952), acidæmia (Harper 1952) respiratory pression due to premedication and thiopentone com ned with hyperventilation (Richards and Youngman 52 Barron 1952) and overdosage with succinyldicholine oldes 1952) The breakdown of succinyldicholine by iolinesterases was demonstrated by Bovet-Nitti (1949) d Bourne, Collier, and Somers (1952) and Evans, Gray hmann, and Silk (1952) found significantly lowered rum pseudocholinesterase levels in patients who recov ed unusually slowly from succinyldicholine Evans al. (1952) also showed that the duration of apnœa llowing the administration of succinyldicholine was proximately inversely proportional to the serum eudocholinesterase level. Bourne et al. (1952) and vans et al (1952) therefore suggested that succinyldi oline should not be given in liver disease severe æmia, or severe malnutrition or after poisoning by mpounds such as insecticides or weed killers, where e serum pseudocholinesterase level might be expected be low Reid and Neill (1952a) recorded two cases apnœa lasting 75 minutes in which the sum olinesterase level was not significantly lowered but ter they found in other cases that the pseudocholin terase levels were considerably depressed (Reid and ill 1952b)

Hall, Lehmann and Silk (1953) who studied the effect succinyldicholine in dogs, suggested that succinyldi oline formed a stable combination with true cholin terase but an unstable one with pseudocholinesterase he combination of pseudocholinesterase was unstable cause the combination led to the hydrolysis of suc nyldicholine; this made more pseudocholinesterase ailable to receive *succinyldicholine*, which was trans rred from its stable combination with the true cholin terase. Evans et al. (1953) demonstrated that the ministration of pseudocholinesterase in purified form ortened the duration of action of succinyldicholine in an, and that it was able to terminate pre-existing nœa There is thus no doubt that the pseudocholin terase level plays the most important part in determin g the duration of apnœa. However it is as well to member that other mechanisms—e.g., central depres on and changes in electrolyte balance and in excitability nerves and muscles—may produce long-continued nœa after succinyldicholine, even if the pseudo olinesterase level is normal. It must have been such ses which had their effect reversed by the administra on of calcium (Mayrhofer 1952) and nikethamide Barron 1952) and play a part in the prolonged effect casionally seen after decamethonium a drug in whose imination pseudocholinesterase has no part.

It is clearly of practical importance to be able to retell which patients are likely to have an abnormally w pseudocholinesterase level. The significance of liver amage undernourishment or cachexia, and previous contact with cholinesterase inhibitors, has already been considered. Several cases have been reported however in which none of these factors seem to apply; the patients appear to be in good health yet they show prolonged reaction to succinyldicholine and a correspondingly low pseudocholinesterase level. Bourne (1953) describes such a patient who on two successive occasions showed prolonged reactions and had an abnormally low pseudocholinesterase level whereas other liver function tests gave entirely normal results. Bourne also refers to a case reported by Davies (1952) in which a healthy militiaman had a pseudocholinesterase level below measurable limits: "Care was taken with this individual to exclude the possibility of his having been in contact with any anti-cholinesterase substance."

In view of these findings the following case may be of interest

Case record

A man, aged 20 was admitted with ten hours history of pain in the left loin He was a Cypriot and his lack of knowledge of English made accurate history taking difficult.

On examination he was apyrexial but flushed, with a white *moist tongue, and tenderness and guarding in the left loin* His heart and lungs were normal, and rectal examination revealed no abnormality Left-sided pyelitis was diagnosed provisionally because the urine looked cloudy and thick A blood-count showed Hb 15·7 g per 100 ml. and white cells 10 000 per c.mm (neutrophils 84%, eosinophils 1%, lymphocytes 14%, monocytes 1%) Mid-stream urine contained some red blood-cells

Treatment — Sulphatriad therapy was begun Intravenous pyelography six days after admission showed poor detail of the calyces on the left side It was therefore decided to cytoscope and examine the patient under anæsthesia.

Premedication was with Omnopon gr $^1/_6$ and atropine gr $^1/_{150}$

Operation —Anæsthesia was induced on the operating table with thiopentone 350 mg (sleep dose) followed by succinyldicholine-chloride dihydrate ('Scoline') 50 mg through the same needle An oral airway was inserted as soon as the jaw was relaxed, and the patient was insufflated with nitrous oxide and oxygen 5 2 litres, no carbon-dioxide absorber being used Cystoscopy and rectal examination were done under satisfactory conditions in about 5 minutes.

As there was no sign of returning respiration at the conclusion of the operation, the patient was taken into the anæsthetic room. There insufflation with pure oxygen (without absorber) was continued for a further 35 minutes, with occasional pauses to see if spontaneous respiration was returning At the end of this period respirations returned, feebly at first and gradually improving during a further ten minutes. The eyelash reflex was now present, but the patient tolerated his airway His condition was deemed satisfactory for return to the ward. On return to his bed he moved a little and tried to remove his airway This was done for him and he nodded his head when asked whether he was all right; he spoke in a slight whisper During the period of insufflation with oxygen his pulse and colour remained satisfactory There was no sign of consciousness. When he was questioned an hour later he said he had regained consciousness during insufflation in the anæsthetic room. He remembered hearing the anæsthetist talking over him but could not understand all that was said He wanted to say that he could not breathe but he could neither move nor speak. He felt air hunger when ventilation was suspended *occasionally He remembered being wheeled back to the* ward and being put into bed

Subsequent Examination and Interrogation.—The patient, a fit muscular young man said that he had been healthy all his life He had never had occasion to see a doctor before his admission to hospital. He had not had previous attacks of jaundice or malaria, and he had no history suggesting amœbic dysentery His present occupation was that of waiter; before leaving Cyprus he worked as a farmer So far as could be ascertained he had not been in contact with any anticholinesterase chemicals.

His blood pressure was 140/85 mm. Hg No physical abnormality was found on re-examination. The pseudocholinesterase *level* was 18 units (normal 51–125) Other liver function tests gave normal results.

As failures of liver function without obvious causes are sometimes due to inherited errors of metabolism, it was decided to investigate the patient's relatives A brother living in this country was quite fit, weighed 157 lb, and had had no illness but appendicitis His pseudocholinesterase level was 8 units, other tests for liver function gave normal results Two siblings, living in Cyprus, were said to be congenitally deaf and dumb

Discussion

There was no indication in the patient's or in his brother's general condition suggesting any debility which might predispose to a lowered pseudocholinesterase level That the increased sensitivity to succinyldicholine was due to this cause is demonstrated by the fact that the patient recovered consciousness during insufflation with oxygen—i e, thiopentone had been metabolised or redistributed. The premedication was unusually light, acapnia was a most unlikely cause, for an absorber was not in use (Bourne 1953) It was impossible to distinguish this patient, when conscious and paralysed, from a fully anæsthetised patient This fact shows the necessity of supplementing oxygen with nitrous oxide during insufflation, as suggested by Bourne

Although the presence of a low pseudocholinesterase level in siblings does not prove that the condition is familial, it is noteworthy that there are other apparently genetic abnormalities in the family

The two brothers were Cypriots, and of three other people in whom we (H L and E S) found an unexplained low pseudocholinesterase level, two were of Mediterranean stock, one being an Italian and the other a Jew Unfortunately it was not possible in either case to examine the blood of relatives

In view of these findings we feel that further cases of sensitivity to succinyldicholine should be published, and if a low pseudocholinesterase level is found which cannot be explained by disease, malnutrition, or poisoning, their families should be investigated for a hereditary or racial basis of abnormally low pseudocholinesterase level

Summary

Apnœa lasting 40 minutes followed the administration of 50 mg of succinyldicholine chloride to an adult Cypriot There was an unexplained low pseudocholinesterase level (18 units)

A brother of this patient also had an unexplained low pseudocholinesterase level (8 units) The possible significance of this finding is discussed

" The Chadwick battle for mains and drains is read of with surprised amusement by those few who study his life but there is still much hard work ahead for those who believe that money spent on the prevention of disease will pay a far higher dividend than money spent on the cure of a disease already established It is a sobering thought that a week's fog in London can cause more deaths than were attributable to cholera in the great epidemic of 1854 The administrative mind finds it difficult, however, to see far beyond a hospital with all its elaborate mystique of diagnosis and treatment The object of medicine must be to reduce the number of hospital beds needed in the country for the sick, not to increase them Not only is this the right humane outlook but it is also sound practical economics "—*Times Literary Supplement*, Oct 6, 1953 p 1

TORULOSIS*

A CASE MIMICKING HODGKIN'S DISEASE AN RODENT ULCER AND A PRESUMED CASE OF PULMONARY TORULOSIS WITH ACUTE DISSEMINATION

W St C Symmers
M D Belf, M.R C.P

PROFESSOR OF MORBID ANATOMY, CHARING CROSS HOSP MEDICAL SCHOOL, LONDON, LATE SENIOR LECTURER PATHOLOGY, UNIVERSITY OF BIRMINGHAM

Fungus infections other than those of the skin mucosæ are seldom recognised in Britain, where the d seated mycoses, except actinomycosis, are often thou of as exotic curiosities unlikely to be met with in practi But there is evidence that they are not as rare here has been believed, and growing awareness of the po bility of their occurrence may encourage their recogniti Thus 8 cases of torulosis, recognised in this count have been recorded (Smith and Crawford 1930, Greenfi et al 1938, Blair 1943, Magarey and Denton 19 Daniel et al 1949, Galton and Whittick 1950, Tay 1953) and the diagnosis of histoplasmosis† has be made in Britain on at least 11 occasions, with mycologi proof in 5 cases (Derry et al 1942, Robb Smith 19 [the case mentioned by Duncan 1945, 1946–47], Lock et al 1953, Symmers 1953) and with less certainty the cases of Arblaster (1950), Crofton (1950), Lamei (1951), and Hutchison (1952)

Since 1946 I have seen 6 cases of torulosis, 2 of his plasmosis, and 1 each of pulmonary blastomyco sporotrichosis, mycetoma, pulmonary aspergillosis, meningocerebral mucormycosis In the same per I have seen only 2 cases of actinomycosis The organ were recognised in the tissues in each case and cultured in all but 4 cases, in which they were identi as cryptococcus, blastomyces, aspergillus, and mucor their histological appearances The patient with my toma was an Arab immigrant from Aden the oth were Europeans normally resident in these islan although all except the patients with sporotrichosis mucormycosis and 2 of those with torulosis had be abroad 4 of the cases of torulosis were straightforwa examples of cryptococcal meningo encephalitis, 2 other cases were unusual and are described here.

Cox and Tolhurst (1946) have given a full account torulosis, of which more than 200 acceptable cases h been published during the fifty-nine years since B (1894, 1895) and Buschke (1895) reported the first cert case (mycologically proved by Benham 1935), o such published observations as are specially pertinent the following cases need be referred to here

The First Patient

CASE RECORD

A mechanic, born in 1920, noticed painless lumps in left side of his neck in July, 1947 His health had excellent until then, apart from mild attacks of ma during military service in Burma and Ceylon from 194 1945 By November, 1947, enlarged lymph nodes palpable in each side of his neck and in the left axilla. Ra graphy of the chest showed enlarged hilar lymph ill-defined opacities in the middle zone of the right lung thought to be tuberculous No tubercle bacilli were in his sputum Biopsy of two nodes from the left n December 1947 was said to show Hodgkin's disease (see below) The patient's general condition was so good that he refused all treatment. He was next seen in March 1949 complaining of tiredness and productive cough during the preceding few months Enlarged lymph nodes, up to 3 cm. in diameter were present in the neck armpits, and right groin and the edge of the spleen was palpable 3 cm below the costal margin radiography of the chest did not show any change Blood: 4 310 000 red cells per c.mm Hb 9·4 g per 100 ml; leucocytes 5900 per c.mm (neutrophils 82%, eosinophils 1%, lymphocytes 7% monocytes 10%); platelets 73 000 per c.mm. On April 5 1949 he was admitted to the Queen Elizabeth Hospital Birmingham for deep X-ray therapy

---

* In conformity with the recommendations of the Medical Committee of the Medical Research Council (M.R.C. randum no 23 1949) the name torulosis is used in this to denote the disease caused by *Cryptococcus* , (Sanfelice) Vuillemin.

† Locket et al. (1953) refer to a patient with histoplasmosis in South Africa, who died shortly after arriving in this Atkinson (1953) confirms that this was the case by Cunningham and Garrod (1950) and recorded by and Brandt (1951)

First Admission

From April 8 to April 22 a total dose of 1000 r each was given to right and left cervical fields both axillæ and anterior and posterior thoracic fields, and of 600 r each to anterior and posterior splenic and right inguinal fields Throughout his stay in hospital the patient had irregularly intermittent pyrexia up to 103·0°F (39·8°C); malaria parasites were not found He was discharged home on May 8 The response to therapy seemed to be disappointing because his general condition had improved little although the spleen and superficial lymph nodes were no longer palpably enlarged. Radiography of the chest showed no change

Progress

By May 27 1949 there was unexpectedly great improvement; the patient felt perfectly well and had had no fever since leaving hospital On Jan 6 1950 he coughed up a little bright blood radiography showed extensive opacities in the right lung and deviation of the mediastinum to the right. In March 1950 two small painless ulcers appeared on the face, one in front of the right ear at the site of an abrasion while shaving and one on the nose where he had accidentally scratched himself with a finger nail These lesions were thought to be typical rodent ulcers and on April 14 the preauricular one was excised histological examination showed that it was a cryptococcal granuloma The patient was readmitted to the Queen Elizabeth Hospital on May 6

Second Admission

The ulcer (1·0 × 0·8 cm.) on the nose (fig 1) had a slightly moist yellowish red base and a low rolled pearly edge surrounded by an ill-defined cyanotic corona 0·25 cm wide There was now a similar lesion, 0·8 cm. in diameter on the left side of the chin, which had also followed a razor-cut The scar following excision of the preauricular ulcer was healthy No other skin lesions were found. There was no lymphadenopathy and the spleen and liver were not palpable; the lower half of each lung was dull to percussion, and there were râles at the right base the other systems were normal

Investigations

Cryptococcus neoformans was isolated from the ulcers sputum, and urine; the urine was otherwise normal and the feces were normal Tubercle bacilli were not found in the sputum or elsewhere at any time during his illness. Intradermal tests with histoplasmin were negative Serum Wassermann and Kahn tests negative Lumbar puncture: clear colourless cerebrospinal fluid (C.S.F.) under a pressure of 120 mm. C.S.F. no block protein 20 mg per 100 ml (no excess of globulin) reducing substances 58 mg per 100 ml., and chloride (as NaCl) 700 mg C.S.F. blood and sternal marrow cultures in routine media and on Sabouraud's and beerwort media remained sterile after twenty eight days. Erythrocyte sedimentation rate 19 mm in one hour (Wintrobe) Blood: red cells 4 700 000 per c.mm Hb 11 g per 100 ml; leucocytes 11 800 per c.mm. (neutrophils 87%, eosinophils 1% lymphocytes 8% monocytes 4%) and platelets 319 000 per c.mm. The number of white cells gradually decreased by June 5 to 5000 per c.mm. (neutrophils 71%, eosinophils 3% lymphocytes 22% monocytes 4%) Sternal marrow: no diagnostic abnormality Blood-chemistry: urea 37 mg. per 100 ml., albumin 4·0 g per 100 ml globulin 2·6 g per 100 ml.; free cholesterol 64 mg per 100 ml., ester-cholesterol 70 mg; alkaline phosphatase 27·0 units (Jenner and Kay) van den Bergh reactions negative thymol turbidity test 0·5 units (Maclagan); cephalin-cholesterol flocculation test 1 + colloidal gold curve 12210 Electrocardiograms normal. Chest radiography: mediastinum displaced farther to the right, and "woolly" opacities in the right middle and lower zones and left upper and middle zones No radiological abnormality of the skeleton.

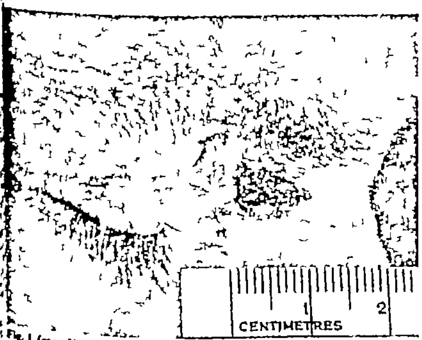

Fig. 1 (case 1)—Ulcerated cryptococcal granuloma of skin (May 1950)

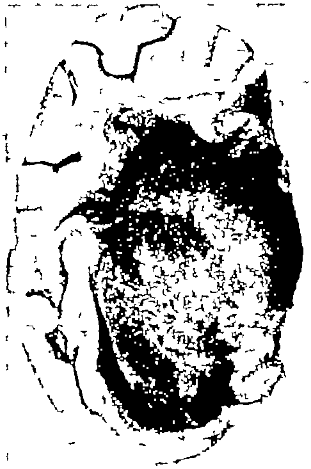

Fig 2 (case 1)—Hæmorrhagic cryptococcal granuloma of brain (gap between the lesion and surrounding tissue is an artefact) (Actual size.)

Treatment

Courses of intramuscular penicillin (500 000 units six hourly total 36 000 000 units) and of sulphadiazine (1·0 g six hourly by mouth, total 50 g) were given over eighteen and twelve days respectively from May 26 On June 8 a course of potassium iodide by mouth was started; the dose was increased from 0·3 g twice daily to 2·0 g three times a day by June 17 at which level it was continued without apparent side-effects until the end of the illness Throughout this stay in hospital the patient had intermittent fever up to 100°F (37·8°C); he had no respiratory symptoms apart from slight cough. His condition did not change and he was discharged on June 18

Progress

On July 21 he had been afebrile since leaving hospital; his skin lesions remained unaltered. On Aug 25 he was back at work and feeling very well although a little breathless on exertion On Oct. 6 he was admitted to hospital elsewhere because of malaise tiredness, and anorexia during the preceding week; the clinical findings were unchanged he had slight fever; a blood-count showed 5 100 000 red cells per c.mm. Hb 12·7 g per 100 ml., and leucocytes 5000 per c.mm His condition improved with rest and he returned home on Oct 16 feeling well but complaining of occasional slight headache for the first time On Oct 20 he had a fit while at work. On Nov 2 he had another fit and until his death in coma at home on Nov 10 major epileptiform convulsions occurred with increasing frequency in spite of treatment with phenobarbitone.

POST MORTEM FINDINGS

Necropsy (Dr W H. J Baker)

The posterior half of the right cerebral hemisphere contained a hæmorrhagic mass (9 × 6 × 5 cm.) which shelled

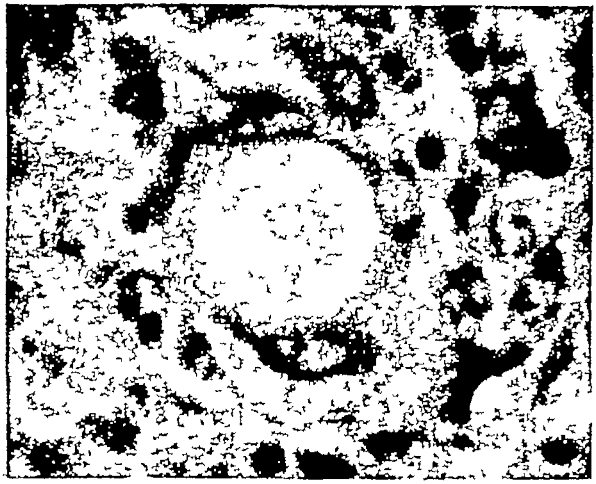

Fig 3 (case 1)—Lymph node biopsy (December, 1947) showing cryptococcus, with typical broad capsule in multinucleated giant cell (Hæmatoxylin and eosin × 950)

out easily (fig 2), the meninges appeared normal There was a small empyema over the lower lobe of the left lung, old adhesions obliterated the rest of the pleural cavities The lungs (each 900 g) showed dense fibrosis of the lower lobes and of the basal and hilar parts of the other lobes, the bronchi were crowded and dilated The upper lobes and the periphery of the lower lobes contained groups of smooth lined cysts (0 1–1 0 cm in diameter) Irregular firm grey nodules (0 2–2 0 cm in diameter) were scattered through the lungs The liver (2020 g) was moderately enlarged, a few white nodules, up to 0 5 cm in diameter, were scattered through it The lymph nodes in the neck, axillæ, and abdomen were firm and moderately large The spleen (500 g) was large, soft, and engorged. The other organs were normal *C neoformans* was isolated in cultures only from the ulcer on the chin, the lungs, spleen, cerebral mass, and C.S F were heavily contaminated with saprophytic bacteria

Histology

All the specimens were fixed in formol saline (4% formaldehyde)

Lymph node biopsy (December, 1947)—Review of the sections showed nothing to support the original diagnosis of Hodgkin's disease the appearances were those of chronic lymphadenitis. No organisms were found in the original sections, examination of 100 new serial sections revealed three typical cryptococci (fig 3)

Cutaneous lesions (fig 4)—The appearances in all three ulcers were identical The ulcerated area was surrounded by hyperkeratotic acanthotic epidermis, there was no evidence of neoplasia The dermis and fascia deep to the margin and base of the ulcer were packed with cryptococci. At first sight most of the organisms appeared to be free in the tissue spaces, under higher magnification traces of histiocytes were seen round many of them. Well preserved foreign body giant cells were numerous at the periphery of the lesions and contained yeasts, singly or in groups. There were a few polymorphs near the ulcerated surface and small clusters of eosinophils and mast cells elsewhere. There was no fibrosis

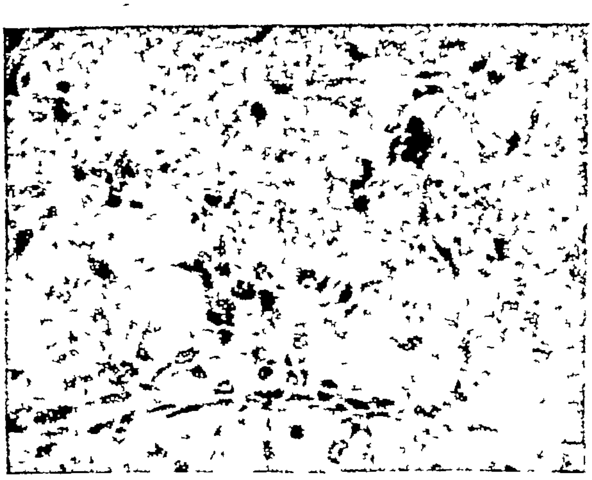

Fig 4 (case 1)—Biopsy of nasal ulcer (May, 1950) showing large numbers of cryptococci in dermis. (Hæmatoxylin and eosin × 400)

Visceral lesions—The pleuræ were fibrotic, no organisms were found in the exudate lining the empyema cavity There was dense hyaline fibrosis of much of the lung tissue, lymphocytic aggregates were numerous in the fibrotic areas, and large, pale, or hyperchromatic cells, some of which resembled the "mirror-image" variety of binucleated reticulum cells were present among the lymphocytes, multinucleated cells and myeloid cells were not found This picture (fig 5) which was seen also in lymph nodes, some portal tracts, and parts of the kidneys, had some resemblance to sclerosing Hodgkin's disease, an occasional cryptococcus was found in the Hodgkinoid tissue, usually in one of the large mononuclear cells The pulmonary cysts were surrounded by hyaline fibrous tissue and lined by simple flat or cubical epithelium, a few of them communicated with the bronchial tree and contained pus Extensive suppurative bronchiectasis and bronchiolectasis were present, gram positive cocci and occasional cryptococci were found in the bronchial exudate and in foci of bronchopneumonia

No evidence of tuberculosis and no acid fast organisms were found in any organ

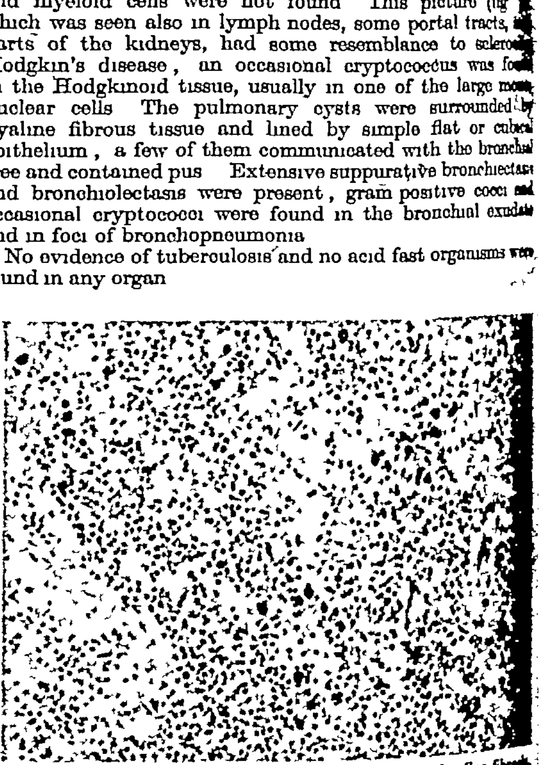

Fig 5 (case 1)—Hodgkinoid tissue (lung), showing hyaline fibrosis, large hyperchromatic cells, and predominance of lymphocytes. (Hæmatoxylin and eosin. × 150)

The nodules in the liver were partly necrotic and consisted of collections of hyperchromatic spindle shaped or polyhedral cells, with larger cells resembling atypical reticulum cells (fig 6), mitotic figures were numerous, no organisms were found in these foci, which had more resemblance to pleomorphic reticulosarcoma than to the Hodgkinoid lesions elsewhere There was an intercellular network of fine argyrophil fibres, least developed where the sarcoma-like tissue infiltrated and destroyed the surrounding tissues. Some cervical, mediastinal, and axillary lymph-nodes contained collections of cryptococci, the appearances being similar to those in the skin lesions, other changes in the nodes ranged from simple reactive hyperplasia and sinus catarrh to sclerosing Hodgkinoid lesions The spleen was engorged The cerebral mass was an accumulation of large pale mononuclear cells similar to those in the Hodgkinoid lesions in the lungs, single cryptococci were found in some of the cells Many vessels in the mass showed recent thrombosis and there was extensive hæmorrhage A narrow zone of brain tissue round the mass was heavily infiltrated by similar cells, the infiltrate extended in the perivascular spaces to the adjacent meninges There was no fibrosis or gliosis

Mycology (Dr H M. Smallwood)

C neoformans was repeatedly isolated from the ulcers and from the sputum and urine Its broad capsule was demonstrated well in nigrosin preparations, budding was observed. It grew well on the common agar media under aerobic cond

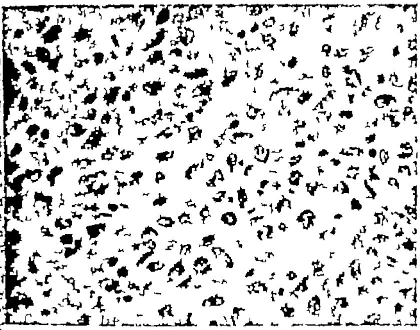

Fig 4 (case 1)—Reticulosarcoma-like tissue (liver) showing several mitotic figures. (Hæmatoxylin and eosin. × 400.)

lous at 37°C and at room temperature. The colonies were mooth and ordinarily white or cream coloured, though old ultures on Sabouraud's maltose-agar medium became tan oloured. No mycelium was produced in cultures kept for p to a year but pseudohyphæ were observed in the peri oneal exudate of experimentally infected mice. Acid, but not as, was formed from glucose, maltose, and saccharose ctose was not fermented. litmus-milk was turned alkaline latin was liquefied in four to six weeks. Intraperitoneal noculation of mice and guineapigs caused a lethal disseminated afection in which the kidneys and brain were conspicuously ffected. The morphological, cultural, and pathogenic haracteristics of the organism identified it as *C neoformans* (Sanfelice) Vuillemin. Sensitivity tests on solid media showed hat it was resistant to penicillin (10 000 units per ml); to strepto mycin, chloramphenicol, and aureomycin (100 µg per ml in ach case); and to sulphathiazole, sulphadiazine, and sulpha midine (10 mg per 100 ml in each case); it was resistant lso to 1 mg of gentian violet per 100 ml, but sensitive to 0 mg per 100 ml.

DISCUSSION

Diagnosis

The diagnosis of torulosis was proved by isolation of he organism. The discovery of morphologically typical rganisms in the lymph node biopsy makes it reasonably ertain that infection with *C neoformans* was of at least hree years standing. The natural duration of torulosis s not known; the duration of most of the published ases was estimated from the time of onset of neurological manifestations, which usually presage death within hree or four months (Cox and Tolhurst 1946). Few ases with longer survival have been reported; the ongest recorded durations are seven years and eight months (case 4 of Reeves et al 1941, Hammack cited by Voyles and Beck 1946) and seven years and three months case 4 of Voyles and Beck 1946); both these patients were still alive, although not cured, when last reported.

Clinically manifest torulosis is not invariably fatal, but he prognosis is almost always bad once evidence of meningo-encephalitis develops. As *C neoformans* has a remarkable affinity for the meninges and brain, torulosis is always potentially very dangerous. Lesions in other parts of the body, however, may heal; published cases of this type reviewed by Gendel et al (1950) were not all mycologically unequivocal, and some were not under observation long enough to justify the presumption of a cure. Unlike other visceral mycoses, torulosis has not yet been shown to occur in a subclinical self-limiting form, but cases in which encapsulated intracerebral collections of cryptococci are an incidental post-mortem finding may be of this nature (Stevenson et al. 1950).

The sources and portals of entry of naturally occurring cryptococcal infection are practically unknown. Carter and Young (1950), who isolated *C neoformans* from a sample of cow's milk in Scotland, found only two previous records of its isolation from outside the animal body—from peaches and from milk.

Several difficulties in diagnosis were illustrated by this case.

Malignant Reticulosis

The patient was long thought to have Hodgkin's disease. As a review of the lymph node biopsy specimen showed nothing more than a chronic lymphadenitis with no resemblance to Hodgkin's disease in support of the original diagnosis, it is remarkable that lesions which resembled those of Hodgkin's disease should have been found post mortem. Cox and Tolhurst (1946) noted that enlarged lymph nodes were recorded in 18% of the cases of torulosis which they reviewed. Though cryptococcal lymphadenitis accounts for the lymph node enlargement in some cases of torulosis, in others tuberculosis (Rappaport and Kaplan 1926), histoplasmosis (Milder et al 1947), sarcoidosis (Gandy 1950), and Hodgkin's disease or some other form of "lymphoblastoma" (Cox and Tolhurst 1946) have been held responsible. Gendel et al. (1950) found that "Hodgkin's disease" had been diagnosed in 14 of the 165 cases of torulosis which they reviewed; in many of the cases the evidence for this diagnosis seems to have been inadequate or was not given in detail. Organisms have not usually been seen in these lesions. Rodger et al. (1951) found that lesions resembling Hodgkin's disease were said to have been present in 3 out of 118 published fatal cases of histoplasmosis, as well as in their own remarkable case of coexistent histoplasmosis, torulosis, tuberculosis, and "Hodgkin's disease." Such observations suggest that certain primary diseases of the lymphoreticular system may predispose to the establishment of mycotic infections, or alternatively that mycotic infections may in some instances evoke proliferative reactions of lymphoreticular tissue which histologically resemble recognised varieties of malignant reticulosis more or less closely.

The evidence in case 1 suggested that the Hodgkinoid tissue was an atypical granulomatous reaction to the fungus infection; cryptococci were found, although with difficulty, in these lesions. Sarcoma-like lesions such as were present in the liver in this case do not seem to have been described before in association with any fungus infection. It is debatable whether they were neoplastic, although their resemblance to pleomorphic reticulosarcomata was close; organisms were not found in them.

Pulmonary Tuberculosis

Although the radiographs had been interpreted as showing pulmonary tuberculosis, no evidence of tuberculosis was found anywhere post mortem. The radiological findings were similar to those which Greening and Menville (1947) described in torulosis. The naked-eye appearances of the lungs were those of cystic disease with fibrosis (cf Cunningham and Parkinson 1950); the fibrosis was associated with Hodgkinoid torulosis, but radiotherapy may have played some part in its development.

Rodent Ulcers

The skin lesions in this case simulated rodent ulcers so closely that the histological demonstration of their non neoplastic nature was completely unexpected. It was therefore interesting to find that a visiting party of American radiologists unanimously suggested torulosis as an alternative diagnosis in this case, and said that in their experience differentiation between carcinoma of the skin and the ulcerative form of cutaneous torulosis can be made with certainty only in the laboratory. Ulcers which are clinically identical with those of torulosis may also develop in histoplasmosis (Rodger et al 1951). Other manifestations of cryptococcal infection of the skin include acneiform and furunculoid lesions; systemic torulosis may be associated also with psoriasiform and other dermatoses from which the organism cannot be isolated (Cox and Tolhurst 1946). Cox and Tolhurst (1946) found that the incidence of cutaneous torulosis in the hundred or so cases which they reviewed was between 4% and 5%.

Skin lesions may be the presenting manifestation of torulosis (Curtis 1950); whether the skin is ever the portal for infection is debatable: as in case 1, the skin lesion observed by Johns and Attaway (1933) developed at the site of a razor-cut, but their suggestion that the fatal meningeal infection was a result of this infection of the skin is not borne out by their account of the patient's history.

Neurological Features

Although necropsy in case 1 revealed a large granulomatous tumour in the right occipital lobe, the patient had first complained of headache only a few weeks before his death. Localising neurological signs were never observed. Daniel et al (1949) indicated that circumscribed cryptococcal granuloma ("toruloma") of the brain is considerably rarer than diffuse cryptococcal meningo-encephalitis. Unlike the "torulomata," which consist of gelatinous masses of cryptococci with little cellular tissue reaction, the circumscribed cerebral lesion in case 1 was a hæmorrhagic mononuclear cell tumour like granuloma in which organisms were scanty.

Treatment

The strain of *C neoformans* which was isolated in case 1 was resistant to various sulphonamides and antibiotics in vitro, and there was no apparent response to treatment with these drugs or with iodide. The inefficacy of treatment of systemic torulosis has been common experience (Mosberg and Arnold 1950), with the possible exception of the sulphadiazine-treated case of Marshall and Teed (1942, 1951). As in case 1, lymphadenopathy accompanying torulosis has been observed to regress after radiotherapy in several cases (Cox and Tolhurst 1946), although with the exception of some cutaneous lesions (Kessel and Holtzwart 1935) irradiation has not been effective against other manifestations of torulosis, and shrinkage of enlarged lymphoid organs is likelier to have resulted from the effect of the irradiation on the lymphoid tissue than from any effect on the organism. Chapman was cited by Stone and Sturdivant (1929) as noting an inhibitory effect of X rays on cultures of the strain of *C neoformans* isolated from their case; their patient, however, did not respond to X-ray therapy. X irradiation had no effect on the strain studied in vitro by Owen (1940).

The Second Patient

CASE-RECORD

A housewife, born in 1925, had good health until December, 1950, when she began to have frontal headaches and pain in the right side of the face; she was 25 weeks pregnant. On March 19, 1951, a submandibular abscess developed on the right side, and was incised because extraction of a tooth did not establish drainage; the incision healed well, but local induration persisted for a few weeks. On March 25 she was delivered of a healthy child, labour and puerperium were normal. On May 16 pain in the left side of the chest was followed by sudden expectoration of about 100 ml of thick brown material. Her temperature was 102°F (38 9°C). Radiography showed a very large abscess in the lower lobe of the left lung and small abscesses in other lobes. Pus from the large lung abscess was sterile; no pathogenic organisms were found in the sputum. Blood: red cells 4,100,000 per c mm, Hb 8 7 g per 100 ml, and leucocytes 8950 per c.mm (neutrophils 85%, eosinophils 2%). Fever subsided during the first days of a week's course of penicillin and streptomycin but rose to its previous level by the end of the week, when a pemphigoid condition of the scalp and painful swelling of one elbow and knee developed. She was admitted to the Thoracic Surgical Centre, Hill Top Hospital, Bromsgrove, on June 6.

Condition on Admission

She was severely emaciated. Her nose was swollen and covered with large hæmorrhagic vesicles, and there were a few similar lesions on the scalp. Suppurative parotitis was present on the right side. The tongue was inflamed and partly covered with small whitish patches. There was an offensive vaginal discharge. The elbows and knees were swollen and very painful. Scattered râles in the right lung were the only other abnormal clinical finding.

Investigations

Blood: red cells 3,500,000 per c mm, Hb 7 5 g per 100 ml, leucocytes 7200 per c.mm (differential count normal). Blood cultures sterile after seven days. Urine: protein +, occasional erythrocytes, leucocytes, and granular and hyaline casts, sterile. Pus from the vagina contained *Trichomonas vaginalis* in large numbers, and culture produced a heavy growth of coliform bacteria and non hæmolytic streptococci. Swabs of lesions on nose and tongue: heavy pure growth of coagulase negative *Staphylococcus aureus*.

Progress

On June 8 a transfusion of 3 pints of blood was given, a course of aureomycin, chloramphenicol, and vitamin complex was started. On June 9 the large pulmonary abscess was drained under local anæsthesia. While being p into position for the operation the patient coughed up pus; cough had not been a feature of her illness, apart the episode on May 16. Little drainage resulted from operation, and there was no appreciable change in her c tion; her temperature still ranged up to 102°F. On J a papular purpuric eruption appeared in the right and within 24 hours covered her body. On June 16 p developed. A heavy pure growth of a yeast was from her sputum, which was now abundant, bloody purulent. Since the organism was presumed to be *C albicans* it was not investigated further; treatment antibiotics was stopped. The patient's condition de steadily, and she died on June 24.

POST MORTEM FINDINGS

Necropsy (Dr C D Cruickshank)

The right pleural cavity was normal; the left pleura cavity was obliterated by organising fibrinous exudate an old fibrous adhesions. The thoracotomy wound opened an "abscess" which occupied most of the lower lobe of th left lung; the thin fibrous wall of the "abscess" was by yellow necrotic material. There was a smaller similar lesion in the upper lobe of the right lung, and another in the middle lobe. The bronchi contained bloody mucopus; no communication was found between them and any of the cavities in the lungs. The liver was moderately enlarged; ill defined firm or purulent yellowish foci, up to 6 cm in diameter, were scattered profusely through it. There was organising fibrinous perisplenitis; the spleen (fig 7) was much enlarged, and its pulp was riddled with focal lesions similar to those in the liver. Similar foci were present in enlarged lymph nodes in the splenic hilus; the lymph-nodes elsewhere appeared normal. Meninges and brain were normal.

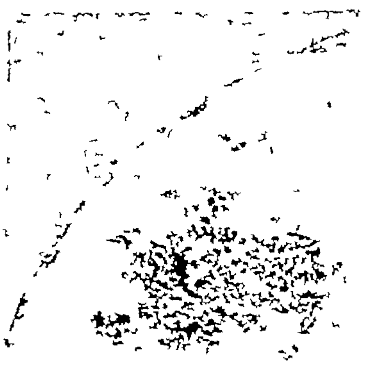

Fig 7 (case 2)—Part of spleen showing confluent abscesses (× 1½)

Histology

The tissues were fixed in formol saline solution.

Appearances of the organisms (fig 8).—The organisms will be described first, because the diagnosis depended on their identification in the sections. They were very numerous in the spleen, lymph nodes, and liver, and were also present in the lungs and bronchi. They were round or ovoid cells 5–10 μ in diameter; their faintly hæmatoxyphil structureless body was outlined by a fine and strongly hæmatoxyphil rim which gave the Feulgen reaction for thymonucleic acid. Further investigation showed that the hæmatoxyphil cell wall was gram positive and coated externally with mucin. The mucin stained metachromatically with toluidine-blue, gave a positive periodic acid Schiff reaction (McManus 1948) and was mucicarminophil; it was not demonstrable after incubation with bull testis hyaluronidase for 24 hours. Although the mucinous capsule was seldom thicker than the cell wall, organisms with the broad mucinous capsule ordinarily characteristic of cryptococci in tissues were found occasionally in all the lesions, particularly in the caseonecrotic pulmonary granulomata and in the bronchial ulcers and exudate. A small proportion of the organisms showed budding.

Viscera.—The lesions which had seemed at necropsy to be lung abscesses showed no microscopical evidence of suppuration but consisted of caseous matter, softening of which had led to cavitation. An incomplete wall of hyaline fibrous tissue intervened between the necrotic material and the adjacent lung, which was fibrotic and infiltrated by lympho-cytes and plasma cells; there were collections of epithelioid histiocytes and multinucleated giant cells at the periphery of the necrotic material The appearances resembled tuberculoma or gumma, but were not typical of either no tubercle bacilli were found but there were occasional yeasts in the tuberculoid tissue Some small infarcts in the lungs showed early organisation the related arterioles were occluded by organising thrombus in which rare yeasts were seen. There was widespread chronic suppurative bronchitis, and some bronchi showed patchy ulceration scanty yeasts were found in tuberculoid tissue in the floor of the ulcers. Yeasts were also present in foci of acute necrotising bronchiolitis and in the narrow zone of pneumonic exudate round them

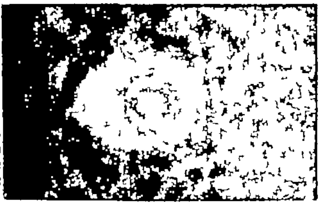

Fig. 8 (case 2)—Typical cryptococcus in pus (spleen) (Hæmatoxylin and eosin. × 900)

The focal lesions in the liver were abscesses; their distribution had no constant relation to the lobular landmarks The earliest lesions showed necrosis of the parenchyma and accumulations of polymorphs yeasts were scanty in them. The larger lesions contained abundant purulent exudate and large numbers of yeasts occasional histiocytes were present but none of them contained organisms and there were no multinucleated forms; the parenchyma and most of the stroma were destroyed and there was no fibrosis. Some lesions involved the walls of tributaries of hepatic veins, and in some instances the abscess had broken through the overlying mural thrombus to discharge into the lumen of the vessel (fig 9) The spleen and some of the lymph nodes, particularly nodes in the splenic hilus were riddled with similar abscesses. The meninges and brain were normal

DISCUSSION

The clinical course and pathological findings in case 2 were unlike those of any case of torulosis in the literature The unusual features make it the more regrettable that the diagnosis of torulosis rests on identification of the organisms only by their appearance in histological sections; the morphological and tinctorial evidence that they were cryptococci, however convincing remains presumptive evidence only. In view of the isolation from the sputum of a yeast which was thought at the time to be *C albicans*, it should be said that the characteristics of the organisms in the tissues were not those of candida

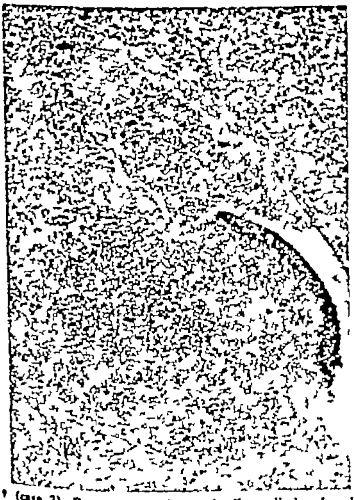

Fig. 9 (case 2)—Cryptococcal abscess in liver discharging into a hepatic vein; dark crescent is thrombus over site of perforation of vessel wall. (Hæmatoxylin and eosin. × 80)

A non-necrotising tuberculoid granulomatous reaction is most characteristic of torulosis and the only common variation is in the amount of the cellular proliferation which is sometimes so inconspicuous that the lesions appear to consist predominantly of great accumulations of cryptococci, among which few tissue cells may be recognisable Caseation is rare (Cox and Tolhurst 1946) and caseous lesions of the large size of those in the lungs in case 2 have not been described. These chronic pulmonary lesions were without doubt the oldest lesions present, and most of the organisms in them were typical cryptococci The true abscesses in the spleen lymph nodes, and liver on the other hand were obviously of very recent development only a small proportion of the great numbers of organisms in them had the characteristic broad mucinous capsule of cryptococci an observation which it is tempting to relate to the poor development of the capsule in young cultures of at least some strains of *C neoformans* (Cox and Tolhurst 1946) Suppuration has been observed only exceptionally in torulosis (Cox and Tolhurst 1946); as it is characteristic of another yeast infection North American blastomycosis (Baker 1942) the latter diagnosis was considered in this case and was excluded because of the structural and tinctorial differences between *Blastomyces dermatitidis* and the organism in question

The distribution of the abscesses suggested reticulo-endothelial phagocytosis of blood-borne organisms as the factor determining the site of these lesions It is possible that cryptococcæmia or cryptococcal septicæmia was a consequence of incision of the pulmonary lesion but, if surgical incision of a cryptococcal lesion could alone precipitate such a fulminating infection as developed in case 2 one might expect to find records of this complication in previous cases, and no similar case has been reported It is conjectural whether treatment with antibiotics played any part in the unusual behaviour of the infection in the terminal phase of this patient's illness though there is some evidence that treatment with antibiotics may predispose to certain mycotic infections and that the presence of certain antibiotics or of impurities associated with them may enhance the growth of some fungi in vitro (*British Medical Journal* 1952) no observations of this kind appear to have been made as yet in relation to cryptococci

The absence of intracranial lesions in case 2 was remarkable in view of the severity of the infection, and was in contrast to the high incidence and overriding importance of meningocerebral infection in the recorded cases of torulosis. The relation between the infection and the lesions observed during life in the skin, mucosæ, and joints is not clear the skin lesions did not correspond to any of those described in association with torulosis. It is impossible to say whether the submandibular abscess was related to the fatal illness, or whether pregnancy or parturition played any ætiological rôle The patient's child was healthy at birth and has remained well Timerman (1930) reported a case of cryptococcal meningo-encephalitis in which cæsarean section was performed post mortem; the baby who died two hours later appeared not to be infected The manifestations of torulosis in infants are said to resemble closely those of toxoplasmosis (Neuhauser and Tucker 1948)

Summary

Two cases of disseminated mycotic infection are described

One case masqueraded as Hodgkin's disease and pulmonary tuberculosis until *Cryptococcus neoformans* was found in lesions which simulated rodent ulcers Cryptococci were found on histological re-examination of lymph-nodes excised when lymphadenopathy first appeared three years earlier Death was due to hæmorrhage in an atypical cryptococcal granuloma of the brain

The second case presented with pulmonary lesions which simulated abscesses but proved to be large caseous granulomata in which morphologically typical cryptococci were present True suppurative lesions, the result of acute terminal dissemination of the infection and containing large numbers of the organisms, were present in the spleen, lymph-nodes, and liver, such lesions have not been described in torulosis previously

I am indebted to Mr B G Scholefield and Dr J F Bromley for permission to publish the clinical history of the first case, to Dr M W Parker for information about the terminal stages of the illness, to Dr A. L P Peeney and Dr H M Smallwood for the mycological findings, and to Dr W H J Baker for placing his post-mortem findings and the viscera at my disposal I also wish to thank Mr R H. F Brain and Dr D J S McIlveen for the clinical summary of the second case, and Dr C D Cruickshank for his report on the necropsy and for the preserved tissues

A ROCKING-BED FOR POLIOMYELITIS

EDGAR SCHUSTER
O B E, D Sc Oxfd

M FISCHER-WILLIAMS
M R C.P E
REGISTRAR, DEPARTMENT OF NEUROLOGY

From the Electro medical Research Unit (Medical Resea Council), Stoke Mandeville Hospital, Bucks, and the Departm of Neurology, United Oxford Hospitals

ARTIFICIAL respiration by rocking the patient wa advised by F C Eve, who found that the gravitation effect on the abdominal viscera caused considerabl movement of the diaphragm with each swing of th rocking apparatus (Eve 1932, Killick and Eve 193 Wright (1947) introduced a rocking bed in America fo weaning poliomyelitis patients from the respirato This method is in use at specialised centres in the U.S.A and Canada but has not to our knowledge been tri in this country One of us (E S) has designed an constructed two rocking-beds which we have foun useful in the rehabilitation of five poliomyelitis patient in the past year

Patients who require a respirator several month after the acute illness are suitable candidates for th rocking-bed Starting with twenty to thirty minute daily, treatment is quickly increased to several hours Th patient may have to be taught to inhale as the hea of the bed rises and to exhale as it falls Nursing car feeding, and physiotherapy may be given while th bed is in motion, but we have not found this necessar Some patients fall asleep while rocking

ILLUSTRATIVE CASE RECORDS

Case 1—Mrs A, aged 40, developed poliomyelitis o Christmas Eve, 1952 She had severe paralysis of the uppe limbs, the intercostal muscles, and the diaphragm, wit lesser involvement of the legs During the first two month she needed positive pressure respiration whenever th respirator was stopped for nursing care

On admission to Stoke Mandeville Hospital on April 1953, she had been out of the respirator for a maximum o five hours at a time She had flexion contractures of th elbows to 30°, slight cough and sputum, and clinical an radiological signs of collapse of the middle lobe of the righ lung The right dome of the diaphgram was paralysed an high There was little or no movement of the left diaphrag

The usual weaning procedures were supplemented by th use of the rocking bed Within the first week the patient wa spending three hours daily on the rocking bed (fig 1), sh was out of the respirator all day, and slept in it only at nigh and for an hour each afternoon Within six weeks the radio logical opacity of the right middle lobe had cleared and ther was no sputum Three months after the start of the trea

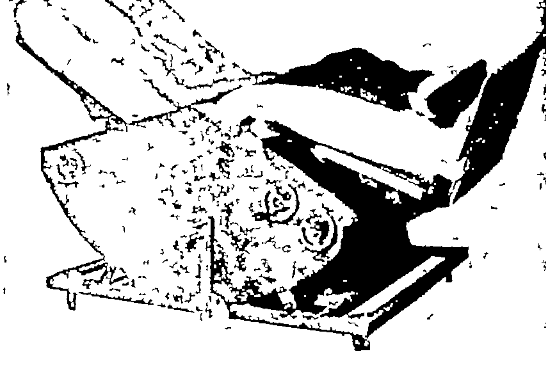

Fig 1—Rocking-bed in use.

ment the excursions of the diaphragm were virtually ormal on both sides Three and a half months after dmission the patient could walk a quarter of a mile, climb tairs, and tolerate a seventy mile car drive She has been weaned to a 'Kifa' cuirass respirator in which she sleeps t night, and was discharged home in November 1953 The ncrease in her vital capacity is shown in fig 2

Case 2.—B C aged 23 developed poliomyelitis on July 13 952. On admission to Stoke Mandeville hospital on Dec 13 952, he was extremely emaciated and had a sacral sore There was no useful movement in the legs and only a little n the arms. He slept in a Drinker respirator and screening n January 1953, revealed very little movement of the intercostals and none of the diaphragm.

Daily treatment on the rocking bed was started A month fter he had hæmaturia and passed urinary gravel This ecurred after a few weeks. Whether this was fortuitous or esulted from the rocking bed treatment is difficult to say enal calculi could not be demonstrated Six months after the tart of treatment both sides of the diaphragm were seen adioscopically to move about 25% of normal The increase n vital capacity is shown in fig 3

The patient was discharged on Aug 15 1953 leading a heel-chair life and sleeping in a kifa cuirass respirator

Case 3.—D.E., a boy aged 10, had acute poliomyelitis in eptember 1950 On admission to Stoke Mandeville hospital November 1952 he slept in a Drinker respirator Treatment on the rocking bed was not started until more than two ears after the acute illness; the increase in vital capacity is shown in fig 2. He now sleeps in a Bragg Paul pulsator nd was discharged home in November 1953

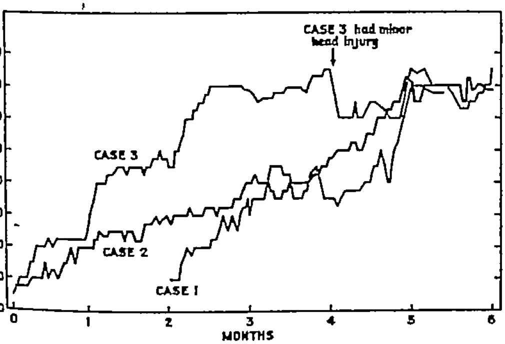

Fig. 2—Vital capacities of three patients during six months treatment on rocking-bed. Time between onset of poliomyelitis and start of rocking-bed treatment was: case 1 four and a half months; case 2, six months; and case 3 twenty-eight months.

DISCUSSION

Since the rocking bed is only one of the means by hich these cases are treated, it is impossible to say xactly what part it plays in their rehabilitation. We hink, however that it not only benefits the lungs and uscles of respiration but also counteracts the ill effects f urinary stasis and improves the circulation and the atient's morale. We have not observed any harm rom this treatment, and regard the rocking bed as a aluable part of equipment

TRUCTURE AND MECHANISM OF THE M.R.C MARK II ROCKING BED

The bed is supported on a rigid stand constructed of ngle-iron bolted and welded at the joints, and carried n four castors. The rocking motion is imparted to a ramework free to oscillate about a centre located as igh as the mechanism permits

The bed top consists of three sections hinged together and f such lengths that the patient's body can be flexed about

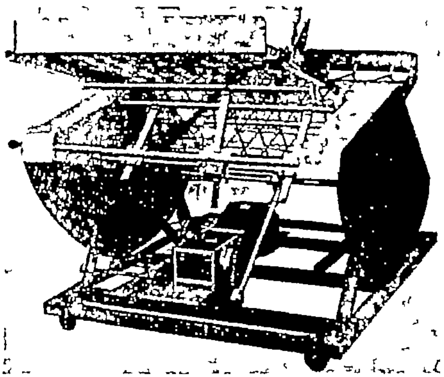

Fig. 3—Rocking-frame.

the hips and about the knees. The three hand wheels shown in fig 1 control the angle of slope of A, the back and head section; B the thigh section and C, the lower leg section. The section A pivots on the frame a few inches from the point at which it is hinged to B The effect of this is that as the head is raised the gluteal region sinks, minimising the displacement of the centre of gravity and the labour involved in turning the hand wheel This important feature of the design was suggested by our colleague Dr F D Stott and contributes to the achievement of our two aims: (1) to keep the centre of gravity as low as possible and (2) to keep the over-all height of the bed small. The object of the first is to allow for smooth and easy rocking and of the second to reduce the strain of lifting the patient on to the bed

A foot-rest is provided which can be moved backwards or forwards and is automatically locked in any position

The rocking frame (fig 3) consists of two inner side members built of aluminium alloy and strip and connected together by distance pieces of Duralumin rod The side members are of the shape of obtuse angled triangles with their base angles truncated, and at the rounded apices of the triangles are housings containing ball bearings. Studs $^{3}/_{4}$ in in diameter fastened from without to the vertical members of the stand with large flanges, form the journals for the bearings, and are the pivots about which the bed rocks Attached to the inner side members are outer members of plywood. The tops of these follow the triangular outline of the inner members, and their lower edges are shaped into circular arcs. A strip of thin metal closes the gap between the upper edges of the inner and outer members on each side Thus the upper part of the stand is completely shut in to prevent any part of the patient, nurse or bedclothes from being caught between a moving and a fixed part

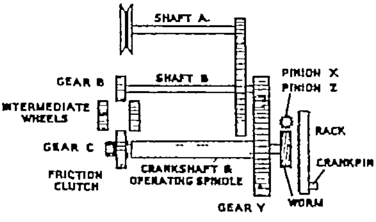

Fig 4—Mechanism.

The bed is rocked with a rotating crank and a connecting rod The small end of the latter has for its gudgeon pin one of the distance pieces connecting the inner members of the frame *The crankshaft is driven at about 16 r p m* by a $^1/_4$ H P motor through a V belt and reduction gearing The final pinion, X (fig 4), meshes with a massive steel wheel, Y, carried at what it will be convenient to call the front end of the crankshaft It is machined so as to form a slideway for the combined rack and crank (shown as "rack" in fig 4) The travel of the crank in the slideway is such that at one extreme the crankpin is coaxial with the shaft and thus conveys no motion to the bed but holds it fixed in the horizontal position, at the other extreme the effective length of the crank is about 5 in and an oscillatory motion of rather more than 40° is imparted

The adjustment of the effective length of the crank is brought about in the following manner A central hole drilled through the whole length of the crankshaft houses the operating spindle This can be made to rotate relatively to the crankshaft by connecting it through gearing to the shaft (to be called shaft B) which carries pinion X at its front end. The spindle and shaft B both carry gear wheels which will be called respectively gear C and gear B When there is no connection between the two wheels, the crankshaft and spindle will turn at the same rate If two intermediate wheels connect gears B and C, the spindle will turn faster than the crankshaft and in the same direction If there is one intermediate wheel, the rotation of the spindle will be reversed The vertical lever shown in fig 1 controls the position of a sector plate carrying on the one side one intermediate wheel and on the other side two When the lever is in the central position, where it is held by a catch, the spindle is free, when it is pushed over into one or the other of the side positions, intermediate wheels are brought into mesh and, if the motor is running, the angle of oscillation of the bed will increase or decrease until the maximum or minimum is reached

Rotation of the spindle relative to the crankshaft acts the crank by a mechanism now to be described. The spind carries at its front end a worm of large diameter relative to pitch, thus the angle of its lead is not much more than and it engages comfortably, if not quite correctly, with straight tooth pinion, Z, whose axis is at right angles to th of the crankshaft This pinion also meshes with a ra integral with the crank Thus, when the spindle rota relatively to the crankshaft, the worm causes the pinion rotate, but at a much slower rate, and the pinion in its tu moves the crank in one direction or the other The tra of the crank is limited at its two extreme positions. either of these positions is reached, no jamming or takes place, because the gear on the spindle is held on shaft by spring pressure against a flange, and slips either end point is reached

SUMMARY

The mechanics of a motor driven rocking bed described

Five patients with respiratory muscle paralysis to poliomyelitis were treated on the rocking bed.

Data are provided, including records of vital cap over six months, which suggest that this is a *means of treatment warranting further trial.*

We wish to thank Dr R B Bourdillon, Dr F D Stott, Mrs P C Stott for their advice and coöperation. Dr Ritchie Russell kindly provided access to the patients his care

Medical Societies

LIVERPOOL MEDICAL INSTITUTION

Management of Paraplegia

A SYMPOSIUM was presented on Nov 5, with Mr J B OLDHAM, the president, in the chair

Mr A SUTCLIFFE KERR paid tribute to the work of Head and Riddoch and to the enthusiasm and determination of Guttman which had led to the establishment of special centres for the care of *traumatic paraplegia* It was vitally important to distinguish at the outset between a complete and an incomplete lesion, for whereas an incomplete lesion was likely to need surgical treatment, with a complete lesion the paraplegia was irrecoverable, and attention must be directed to early reablement the vertebral lesion might be ignored The development of pressure sores was a reflection on the medical and nursing care they could be prevented—but only by unremitting attention Either the patient must be turned two-hourly, night and day, or he must be taught to be "pressure conscious" *and encouraged to sit up in a* wheel chair as soon as the diagnosis of a complete lesion was established (as it could be within a few hours of injury)

Cases of traumatic paraplegia should be transferred, at the earliest possible moment, to a spinal injury centre where they would have the care of specially trained nursing staff and of a properly equipped reablement unit Of 6 cases admitted to Southport within a week of injury, none developed any pressure sores, and urinary complications were slight These patients were fit for discharge home, and ready for some occupation, in from six to twelve months This contrasted with results in patients admitted weeks or months after their injury almost without exception they had had pressure sores, urogenital infections and joint contractures Reconstructive surgery took months or years, and their inpatient treatment might last from eighteen months to three or four years, with an indifferent fin result

Dr MARCK DAMANSKI, discussing nursing and phys reablement, said that pressure sores must be avoided repeatedly changing the patient's position in bed, and night Patients admitted with pressure-sores mig need prolonged nursing in the prone position, and th might lead to hyperextension of the pelvis and hi joints and the later development of contractures Ea mobilisation of the patient prevented this, and did result in further neurological deterioration No inter fixation or back supports were used Physical exerc restored the lost sense of balance and overdeveloped th non-paralysed muscles Walking exercises came and should be preceded by elimination of severe spastic or deformities Lesions higher than D9 were a gr *handicap to walking*

Mr NORMAN GIBBON found the management of the paraplegic bladder an exercise in applied physiolog A cord injury above the sacral segments allowed unc trolled spinal reflex micturition—the "upper neurone bladder" A lesion of the sacral segments the selves left the bladder paralysed, but the urine wa expressible by abdominal straining—and thus he call "the (relatively) lower motor neurone bladder" initial management of the bladder depended on experience of the surgeon and his facilities Co drainage with a fine urethral catheter gave good in hospital, but in front-line conditions, sup cystostomy was safer

Mr J COSBIE ROSS discussed the results of failure achieve satisfactory automatic voiding with a residual urine *The obstruction of the bladder* might be organic, requiring periurethral Spastic obstruction of the external and internal sp was diagnosed largely from the cysto urethrogram. spastic obstruction he had done bilateral p neurectomy in 20 cases, with satisfactory results, p operative cysto urethrograms showed wide opening of previously closed prostatic urethra Stone formation back pressure effects, and urinary infection were all becoming less menacing as a result of modern methods of treatment, and there had been a dramatic improvement in the prognosis for patients with spinal injury

Mr GEOFFREY OSBORNE did not think that splinting operations were indicated when paraplegia was complete but reduction and splintage were of great value in incomplete lesions

Mr R P OSBORNE said that if all patients suffering from paraplegia were admitted to paraplegic centres within a few hours of the injury decubitus ulcers would not develop Meanwhile plastic surgeons had to find ways of healing such ulcers The general condition of the patient must be made as good as possible his hæmoglobin level must be raised by means of a high protein intake, and local infection reduced by frequent dressings carried out in a treatment room with full aseptic ritual This routine, without the aid of local antibiotics (which were usually useless), resulted in healthy granulation tissue on which patch autogenous split thickness skin grafts were applied Once these had coalesced massage was given daily to all surrounding tissue to reduce the induration As soon as possible carefully planned local flaps of skin and fat were transposed or rotated to replace the skin grafted area and so provide a sound cover By this time the patient was as "sore-conscious" as the surgeons and nursing staff and took care never to sit or lie still except for short periods.

Mr KERR, in replying, discussed the control of flexor spasms by mephenesin peripheral nerve section and tenotomy alcohol block in the lumbar theca and anterior rhizotomy by laminectomy Sexual activity was not necessarily completely lost Special provision must be made for the patient's well being when he went home He needed a special bed and bedding special toilet facilities, doors which allowed access for wheel chairs and ground floor accommodation. Above all he should be encouraged to undertake a regular gainful occupation, preferably outside the home The general practitioner could do much to maintain the morale of these patients and could watch for the earliest signs of complications He could also treat successfully a minor flare up of urinary infection but if the patient had to stay in bed for any reason the closest watch must be kept on old healed pressure sores If these broke down, or if urinary infection got out of hand the patient should be returned to his parent special unit as soon as possible and he should in any case return at intervals for routine checks on his progress

---

New Inventions

AN ADJUSTABLE HEAD CLAMP FOR THE OPERATING TABLE

DURING operations on the jaws the patient's head may be steadied by the hands of anæsthetists or nurses, by special pillows or sandbags or by a mechanical head-clamp For twenty years I have used a head-clamp and found it valuable, but it has had limitations, which I have now tried to overcome in devising the simpler model here described.

The base (fig 1) consists of a steel plate readily attachable to the end of the operating table by two stout C-clamps with easily turned hand-screws On this is attached a 'Hydraclamp' hydraulic universal joint, to the arm of which are fixed adjustable callipers which hold firm the patient's head Once the patient's head is fixed in the callipers there is only one mechanism to operate to position the head—i.e the locking wheel of the hydraclamp

There is no difficulty in towelling up (fig 2), because the callipers can be swung out of the way when the towels and mackintosh are placed under the head The callipers are next swung into position and tightened and the edges of the towel are brought up over the patient's upper face and head and over the callipers. Any anæsthetic apparatus may be attached to the clamp Should it be necessary to alter the head position the anæsthetist or a nurse can unscrew the hydraclamp the surgeon can alter the position of the patient's head and the screw can be locked tight once more

The clamp may be left attached to the table for successive cases: it is only necessary to undo the calliper and to raise and swing it away from the patient

It is advisable to cushion the pads with 'Sorbo rubber—$^1/_4$ in. thick for the vertical pad and $^3/_4$ in. thick for the temporo parietal ones.

The calliper arms are not adjustable for length, because they conveniently fit any adult head To use the clamp on a child it may be necessary to build up the vertical pad more thickly Two different heights from the table are available by rotating the calliper section.

This head-clamp ensures rigidity and avoids the fatigue of steadying by hand. Its robust construction will withstand the ministrations of theatre staff

Any inquiries about it should refer to the Oxford head clamp and be addressed to Mr W J Phillips, Loach Electrical Co., 17 Old High Street, Headington, Oxford

Churchill Hospital,
Headington, Oxford

Reviews of Books

Clinical Genetics

Editor ARNOLD SORSBY London Butterworth 1953 Pp 580 90*s*

Professor Sorsby's intention in editing this volume was to produce a book to which the medical practitioner could refer for an up-to-date account of the part played by inheritance in any particular condition in which he was interested In the clinical section—three-quarters of the book—he has assigned one bodily system to each of his contributors These come mostly from the United States, Great Britain, and the Scandinavian countries He has taken considerable pains in allocating space to balance the medical importance of any particular system with what is known of its genetics if genetic information alone had been the criterion, diseases of the eye, the skin, and the nervous system would have occupied half the book But since there are already good books on the genetics of the eye and the skin the authors of these sections are better able to give succinct accounts of the more important disorders, and refer the reader to larger works Other contributors, allowed more space, give much more detailed accounts of the evidence on which current opinion about the inheritance of individual disorders is based Unfortunately there is not yet an experienced geneticist working in every field of clinical medicine, and one or two experts, for one reason or another, have not been able to contribute to this book One or two sections have therefore had to be written by a physician better informed clinically than genetically or by a geneticist more familiar with other specialties These authors have been by no means unsuccessful, but clinical or genetic experts will probably be able to detect occasional errors in the descriptions of particular conditions One such instance is the account of cystinuria, where the two main clinical types (clearly differentiated by paper chromatography and by genetic studies) are not distinguished Most sections, however—for example those on physique, ophthalmology, psychiatry, neurology and cancer—are written with a sure hand The illustrations are very good indeed The theoretical section will be of less immediate value to the practising doctor, but much of it makes fascinating reading Professor Neel's account of the progress that has already been made in the study of the symptom-free "carrier" will be a revelation to many readers It is much to be hoped that the book can be kept up to date by new editions

Emotional Factors in Skin Disease

ERIC WITTKOWER, M D , BRIAN RUSSELL, M.D London Cassell 1953 Pp 214 32*s* 6*d*

THIS well-written book should interest even those who do not agree with the authors' conclusions It begins with a general discussion of the psychosomatic approach to dermatology The anatomy and physiology of the skin are then described in an effort to show how emotional factors can produce sensations and objective changes in the skin , and perhaps more is made of the hypothetical functions of the dendritic cells than facts permit In the second part of the book the results of psychiatric investigation in many specific disorders of the skin are described Dermatitis artefacta, malingering, and occupational dermatitis deserve more attention than they receive here, and it would be interesting to know more about the emotional difficulties of patients with manifestly organic disorders—such as unsightly nævi or long-standing lupus vulgaris—or of patients with some dermatoses (e g , dermatitis herpetiformis) which, though incurable, are satisfactorily suppressed by treatment But it is an enjoyable book

Ciba Foundation Colloquia on Endocrinology

Vol 7 *Synthesis and metabolism of adrenocortical steroids* Editors W KLYNE, M.A , PH.D , G E W WOLSTENHOLME, O B.E , M.A., M.B , MARGARET P CAMERON, M.A , A B L.S London J & A. Churchill 1953 Pp 298 30*s*

THE development of knowledge of the hormones of the adrenal cortex has resulted in a mass of facts, hypotheses, and speculation of a complexity to which it would be difficult to find a parallel The Ciba Foundation, in the pursuit of its beneficent aims, brought together many of the leaders of laboratory work in this field in the summer of 1952 The colloquia were wisely managed and led to a free interchange of ideas in the discussion , and these, while remaining lively and colloquial, have been wisely edited Half the present book deals with chemical problems of synthesis, and half with the biochemical problems of formation in the body and of metabolism A speculative and unsure bridge between the two is provided, perhaps, by a paper on the transformation of steroids by X rays, an agent which sometimes mimics vital metabolism The colloquists will welcome these memoranda of their meeting , and specialists in the field will find both useful summaries of work published in scattered papers and inspiration for trains of thought The general reader on the other hand will find most of this difficult and heavy going He may, however, conclude that the chemical part gives no ground for expectation of cheap cortisone, and the biochemical part no theoretical basis for the empirical successes (and disappointments) in clinical practice

Experimental Atherosclerosis

LOUIS N KATZ, M D , director , JEREMIAH STAMLER, M D , research associate, cardiovascular department, Medical Research Institute, Michael Reese Hospital, Chicago Springfield, Ill Charles C Thomas. Oxford Blackwell Scientific Publications 1953 Pp 375 70*s*

FOR more than a decade the ætiology of atherosclerosis has been the major research project in the cardiovascular department of the Michael Reese Hospital More people die as the result of circulatory disease than from any other cause—a very large proportion of them from atheromatous plaques in their coronary or cerebral arteries. But the idea that atheroma is an inevitable accompaniment of advancing years has discouraged many would-be investigators in this field Dr Katz points out that arteriosclerosis, not atherosclerosis, is the ageing process of the arteries and with a large group of workers has been trying to discover why some people develop significant atheromatous disease

The title of the book is somewhat misleading and likely to dissuade clinicians from investigating its contents This is unfortunate because the first 120 pages contain an interesting survey of atherosclerosis in different races and in various diseases There is also a well-documented account, with numerous references, of the relationship of human atheroma to plasma cholesterol levels, cholesterol phospholipid ratios, and the concentrations of the lipoprotein fractions separated by Gofman's technique The second part of the book is a review of the studies performed in Dr Katz's laboratories on experimental atheroma in chicks, its relationship to the cholesterol content of the diet, and the ways in which it may be modified by hormonal and other means The results are compared to those obtained by other groups investigating atheroma production in the dog, rabbit, and rat

It is perhaps a reflection of current American therapy that the authors are at great pains to show that lipotropic factors are of no value in the prevention of atheroma. They fully appreciate the uncertainty of translating the results of animal studies in this field to human pathology, and to English readers it may appear that a remarkable amount of time, labour, and money has been spent in investigating a subject of doubtful practical significance.

The Medical Annual (Bristol John Wright 1953 Pp 532 27*s* 6*d*)—A few weeks ago the death of Prof. A. Rendle Short broke the editorial partnership with Sir Henry Tidy which had enhanced the annual's place as a respected friend to doctors all over the world Professor Rendle Short had been joint editor since 1919 This new edition, the last with which he was associated, is the seventy first in the annual's history For a relatively small sum each year, regular readers can keep themselves in touch with much of medical progress This year nearly 50 contributors have combined to provide this welcome service , and the editors have seen to it that no important news has been overlooked For Coronation year, Prof Charles Singer has written an article on medicine in the reign of Elizabeth I, and the book opens with this.

Prognosis of Hypertension

FURTHER outlook unsettled! This familiar phrase still summarises our knowledge of the future of the average patient with essential hypertension. We know these days that the stout old lady with her cherished but symptomless "blood pressure" will almost certainly last as long as her contemporaries, and that on the other hand the young man with albuminuria and papillœdema has probably only a few months to live. But the prognosis for the majority of patients who fall between these extremes, is less easily assessed.

This problem has become especially important since the introduction of powerful medical and surgical means of lowering the blood pressure. Hexamethonium, despite some drawbacks, is an undeniably effective hypotensive agent; and as regards surgery, while sympathectomy has fallen somewhat out of favour, subtotal and total adrenalectomy now claim our serious attention. Such therapy is not to be undertaken lightly. Hexamethonium injections are troublesome and unpleasant side-effects are common; operation is risky and the results are not certain. Thus the selection of patients for such treatment is no easy task. Merely to relieve symptoms is an insufficient aim. In uncomplicated cases the symptoms are often due to anxiety about the blood pressure[1] and even when this is not so, the symptoms can usually be much relieved by simpler methods. Without doubt the primary object of administering hexamethonium or of operating must be to prolong life and health; and until we know a good deal more about the natural history of the disease we shall continue to have difficulty in choosing patients for this treatment and in judging its success. Nevertheless certain broad trends are becoming clear. PALMER and MUENCH[2] have lately published a careful follow up of 453 cases, each observed for at least ten years. The patients were originally classified in four grades: grade I, with very slight or no organic change in the heart, kidneys, or brain detectable by ordinary clinical examination; grade II with definite or pronounced change but with no functional impairment; grade III with functional impairment; and grade IV with papillœdema as well. All the patients were simply treated on conventional lines and none had any specific therapy. After ten or more years 64% of grade I, 42% of grade II, 11% of grade III, and 4% of grade IV were known to be alive. From these and other data PALMER and MUENCH draw some general conclusions about the course of hypertension. The relative risk of death is greatest in young persons and decreases rapidly with age. Women live longer than men, and in them the disease seems to run a milder and longer course; elderly women with mild hypertension seem no more likely to die than their contemporaries with normal pressures. Duration of the disease, making allowance for simultaneous ageing, seems to have little effect on mortality. There is a tendency for average age to increase from grade I to grade III, which seems to indicate that patients tend to deteriorate gradually from one grade to the next; but a considerable proportion of patients remained throughout in their original grade.

These conclusions are more or less what might have been expected, though it is perhaps rather surprising to find so little relation between mortality and duration of disease. The conclusions seem to confirm LEISHMAN's[3] suggestion that there are two forms of non malignant essential hypertension. In the "benign" form the disease progresses, if at all, very slowly. In the "accelerated" form the march of events is relatively rapid, though of course nothing like the *Blitzkrieg* of the malignant phase of hypertension. The disease seems to assume one or other of these forms from the very beginning, and only rarely does "benign" hypertension become "accelerated"—as rarely, perhaps, as does a non malignant case become malignant. Nevertheless, these occasional metamorphoses support the view that we are in fact dealing with one disease—essential hypertension—and not with two, or three diseases, as some have suggested. LEISHMAN's subdivision follows logically from previous observations that in general, prognosis depends not so much on the actual height of the blood pressure as on the rate at which it is rising.[4] If the rate of rise has been very slow, very high pressures may be well tolerated and the outlook be favourable. Obviously, however, such a situation can exist only in elderly patients. A very high pressure in a younger person must mean that the rate of rise has been relatively rapid and therefore that the prognosis is not so good. LEISHMAN believes that when in a young or middle aged patient at rest a diastolic pressure of about 130 mm Hg is reached the advance of the disease is hastened.

Before deciding for or against giving hexamethonium or operating it is manifestly important to decide whether the patient has the "benign" or the "accelerated" form of hypertension. LEISHMAN gives some valuable guidance, but judgment may still be difficult, particularly in the case of a youngish man with a moderately raised pressure who as yet shows no evidence of serious damage to the vital organs. It is tempting to treat such people actively, on the sound principle that prevention is better than cure; but then many whose hypertension is "benign" will be subjected unnecessarily to the risk and discomfort of operation or of courses of drug taking; many of the unduly favourable reports on sympathectomy have undoubtedly been derived from series that included cases of this type. The wiser course at present is to observe the patient for some time and to note the rate of rise, if any, of his blood pressure—though admittedly the maximum rate of rise that can be viewed without apprehension is still not clearly established, and also the danger of inducing anxiety by frequent use of the sphygmomanometer must be borne in mind. When cardiovascular complications are present, or when there is evidence of definite strain on the heart or kidneys, the question of treatment is more easily settled; for then in all but the elderly, the prognosis is unfavourable This is reflected in the follow-up by PALMER and MUENCH the survival-rate fell from 42% in grade II to 11% in grade III Radical treatment is clearly called for, even though its long-term results in this type of case are unknown Malignant hypertension has so grave a prognosis that such treatment is always urgently indicated It is rather surprising to learn that PALMER and MUENCH found even 2 out of 50 patients in this group alive after ten years, but spontaneous regression takes place occasionally[4]

Thus the forecast of untreated hypertension is gradually becoming a little clearer Further clarification would be greatly hastened by an agreed uniform system of grading In some systems the grades are too vaguely defined Others rely over-much on subjective interpretation of clinical data—the system used by PALMER and MUENCH seems open to this criticism SMITHWICK's[5] method of assigning a numerical value to various significant clinical findings, and grading the patient according to the sum of these values, seems sound in principle, though possibly his present classification gives too little weight to the retinal appearances Some such system will probably prove the best, but it may not be easy to reach general agreement on the relative importance of the various findings

The Anæsthetist's Responsibility

THE anæsthetist's responsibilities are steadily growing, and WHITACRE[6] has named three main causes first, the great increase in elective operations on good-risk patients, second, the increase in the number of long and complex operations, the success of which depends to some extent on the anæsthesia, and third, the ever-increasing number of operations on poor-risk patients To these three causes WHITACRE might have added the gain from modern drugs and techniques, including induced hypotension, which aid the surgeon and whose safety and success depend on the anæsthetist's judgment The anæsthetist is clearly responsible for the choice and administration of an anæsthetic, and he may be legally accountable for any resulting injury[7] There are, however, times when immediate responsibility could equally be assumed either by the anæsthetist or by the surgeon

During a major operation the anæsthetist can best assess the patient's state and give intravenous infusions, but not everyone agrees that the decision to initiate such treatment should be his

Acute respiratory infection is a contra-indication to all but essential operations, since it enhances the risk of postoperative pulmonary complications This seldom leads to disagreement, but the prevention and treatment of postoperative pulmonary complications sometimes does Perhaps the most helpful measure is the administration by inhalation of a vasodilator such as isoprenaline, and postural drainage with vibratory and clapping percussion of the chest[8] Should this rest with the anæsthetist or with the surgeon?

MORTON and WYLIE[9] described a series of deaths due to regurgitation or vomiting during anæsthesia, and suggested that this catastrophe, being related to food or fluid in the œsophagus or stomach, was preventable by precautionary measures Preparation for an emergency operation may necessitate the introduction by the anæsthetist of an œsophageal tube, but not all surgeons and obstetricians would like him to undertake this.

During the operation the surgeon wants the patient in the best position for operating; but the anæsthetist may find that this impairs circulatory or respiratory activity The surgeon may claim that a steep Trendelenburg position is essential for the satisfactory performance of, for example, combined asynchronous abdominoperineal resection of rectum, and that his supports would interfere with the operating field or would not hold the patient in a suitable position, while the anæsthetist may say that the only other way of keeping the patient in this position—i e, by shoulder supports—entails the risk of brachial plexus palsy even though the arms are kept by the side

In many hospitals diathermy is used routinely in operations, and there are occasions when the most satisfactory anæsthetic sequence includes an inflammable agent A decision must then be reached as to which of these—the diathermy or the inflammable anæsthetic—is needed most by the patient

In the immediate postoperative period the choice of sedatives and pain-killers must depend somewhat on the anæsthetic technique at the foregoing operation. Who, therefore, should prescribe these drugs?

Surgeons may prefer certain types of anæsthesia and physicians commonly advise against some anæsthetic technique, or in favour of another, for operations complicated by medical disease These opinions are valuable, but should not overrule the choice by the anæsthetist, who is ultimately responsible, and, if suitably trained, is in a better position to select the most suitable technique In a well balanced team these matters are discussed and settled without argument or direction, but if agreement cannot be reached the anæsthetist would be unwise to adopt a technique which in his opinion might be injurious Beyond this, it is often not possible (nor perhaps is it desirable) to make a sharp division between the responsibility of the anæsthetist and that of the surgeon—though the improved training and status of the anæsthetist, and the growing scope of his work are bringing him to the fore The field of each has to be defined only in legal actions or when surgeon and anæsthetist cannot readily work together—and happily for the patient, this situation is rare

Lung Lesions in Arthritis

CHANGES in the lungs are associated much less commonly with rheumatoid arthritis than with some of the other mesenchymal diseases of unknown origin. Where pulmonary lesions have been regarded as a manifestation of the "rheumatoid disease," the radiographic picture has usually been of diffuse reticulation ELLMAN and BALL[11] reported three such cases, 2 of which came to necropsy Histologically the lungs showed interalveolar fibrosis with mononuclear-cell infiltration Similar cases were later described by LEYS and SWIFT[12] and by BLOOM and RUBIN[13] In a study of visceral lesions associated with rheumatoid arthritis, BAGGENSTOSS and ROSENBERG[14] examined the lungs from 30 cases and failed to find any lesions which could in any way be considered specific, though a high prevalence of adhesions suggested that the pleura was commonly involved. Necropsy studies in cases of rheumatic fever have likewise failed to establish "rheumatic pneumonia as a specific entity. In scleroderma diffuse fibrosis is not uncommon, and characteristically produces a reticular pattern in the lower half of the lung fields.[15] In systemic lupus erythematosus RAKOV and TAYLOR[16] and FOLDES[17] have described a chronic interstitial pneumonitis which may lead to collapse of lung and respiratory failure. BAGGENSTOSS[18] confirmed this and described a peculiar basophilic mucinous œdema of the alveolar walls and of the peribronchial and perivascular tissues, associated with the interstitial pneumonitis and with alveolar hæmorrhages. A relation between lung lesions and joint disease is clearly evident in hypertrophic pulmonary osteo-arthropathy. The mechanism of the changes in the bones and joints in this condition remains obscure, though FRIED[19] suggested that "dyspituitarism" is a factor. Where the lung lesion is neoplastic, pain in the joints is often quite severe and with the associated swelling and stiffness may simulate rheumatoid arthritis. The fact that joint symptoms may be the presenting manifestation of a bronchial neoplasm is well known.[20] This sequence arose in each of the 14 cases of acute pulmonary osteo arthropathy collected by RAY and FISHER[21] in a series of 130 cases of carcinoma of the lung.

Much more florid lung lesions than the interstitial pneumonitis occasionally reported hitherto may apparently be associated with rheumatoid arthritis when the patient is exposed to dust inhalation. From a study of coalminers seen by the Cardiff Pneumoconiosis Medical Panel, CAPLAN[22] has discovered a relation between an arthritis of rheumatoid type and the presence of massive shadows in chest radiographs. Of 14 000 claimants for pneumoconiosis disablement benefit, 51 were found to have rheumatoid arthritis. About 90% of these 51 had massive pulmonary fibrosis compared with only 30% of all the men examined. Furthermore in 25% of the arthritics the radiographic opacities in the chest were of a distinctive type often easily distinguished from the usual appearances of progressive massive fibrosis. The characteristic feature was the presence of multiple, well-defined, round opacities 0 5–5 cm. in diameter, distributed throughout both lung fields but particularly common at the periphery. In cases with this type of lesion the background of simple pneumoconiosis was commonly slight or absent. The opacities seemed to develop rapidly, within months, and thereafter to remain stationary in the majority of cases. The remainder of the arthritics showed either typical massive fibrosis (with opacities which were less well defined, more irregular in outline, larger, rarely more than two in number, and commonest in the right upper zone), a mixture of typical fibrosis and 'round' lesions, opacities indistinguishable from unmodified tuberculosis, or (in 4 cases only) simple pneumoconiosis alone. The severity of the joint lesions was unrelated to the extent and character of the lung changes. Constitutional symptoms were notably absent, even when tuberculosis was suspected, and respiratory function was usually not greatly impaired.

CAPLAN points out that in order to discover whether a relation exists between dust inhalation and rheumatoid arthritis it would be necessary to compare the incidence of rheumatoid arthritis in non miners with that in miners without pneumoconiosis, with simple pneumoconiosis, and with massive pneumoconiosis. In another coalfield the prevalence of rheumatoid arthritis was reported to be higher in non miners than in miners.[23] The true nature of the lung lesion encountered in CAPLAN's cases cannot be established until the difficult task of obtaining material for histological examination from an early case is accomplished. In 3 fatal cases the lesions were composed of fibrous tissue; tubercle bacilli were identified in each of these. CAPLAN suggests tentatively that the lesions are probably allied to tuberculomata and are a form of tuberculosis modified by dust. He believes that the joint changes may be a manifestation of "tuberculous rheumatism." The existence of "tuberculous rheumatism" as a true entity has been debated at intervals ever since PONCET suggested the possibility in 1897, but in the absence of clear diagnostic criteria the majority of clinicians probably remain sceptical. Whether or not CAPLAN's observations can be regarded as providing new support for this concept, he has clearly uncovered an intriguing and hitherto unrecognised syndrome, and clinicians will be on the watch for this in other areas where the hazard of dust inhalation is encountered.

Annotations

SMOG MASKS

LAST week the Minister of Health announced in the House of Commons that doctors could prescribe under the National Health Service "smog masks" for patients with cardiac or respiratory disease. The Ministry has developed two very simple designs: one is like an ordinary surgical mask and the other a cotton tissue pad held over nose and mouth by a soft metal frame. The surgical mask has the less resistance to breathing but unfiltered air can enter quite easily at the sides. The frame mask if carefully shaped to the face is much more efficient; but it is also more of a respiratory obstruction. For the healthy person each is no more than a somewhat tiresome encumbrance; for the dyspnœic patient, however, even the slight respiratory resistance may be unpleasant, particularly with nose breathing in the frame mask. Some people will find a woollen scarf over nose and mouth a more convenient arrangement: the Ministry has itself remarked that this would probably be as effective as the surgical mask.

A number of practical questions arise. When should the mask be put on? Should one wait till early symptoms appear or instruct the patient to protect himself as soon as the atmosphere thickens? Need people on the fringes of a polluted area bother with masks? Where should one strike the balance between avoiding respiratory resistance and providing protection? These questions can be answered only by experience. But it must be remembered that (as the Ministry has already pointed out) such masks cannot provide complete protection, and also that polluted fog only becomes really dangerous when it is very cold.[24] One might suggest, therefore, that if the weather is cold (approaching freezing point) a bronchitic should be advised always to wear a mask whenever a fog develops to which he must expose himself, but that under warmer conditions he need wear a mask only if the fog is exceptionally thick and dirty, or if he begins to feel a need for some protection There seems no point in sentencing people to be mask-bound unnecessarily It would be sensible if the patient could work out in advance how to make least disagreeable whatever device suits him best—for instance, by adjusting the tapes or (if necessary) the filter-pad or by obtaining a scarf of comfortable thickness Other less dramatic measures should not be forgotten verifying that both bedroom and living room can be kept warm in cold weather, seeing that fog shall be excluded as far as possible, and arranging, if possible, that the patient can stay at home whenever a severe fog occurs

The analogy with the cholera epidemics and the *Sanitas Sanitatum* campaign of the last century is provocative The mortality-rate is similar or greater, the ultimate cause is a social one yet the immediate pathogen is not known, and it has needed a really spectacular death-rate to focus attention on conditions which have been lethal on a small scale over decades or perhaps centuries Reflection on the analogy suggests that, today, public-health measures to clean the air are going to be more rapidly effective than experimenting with filters of inhaled air, necessary though these may be in the short term But whether prevention or cure be the more important, the most urgent need for both is to know what the dangerous pollutants are grit, smoke, sulphur compounds, tarry matter, or some specific organic substance or group of substances Such knowledge, telling us what the air should be purged of, could do more than anything else to prosper our twentieth-century campaign for *Claritas Claritatum*

SYNTHETIC PITUITARY HORMONES

UNLIKE the hormones of the anterior lobe of the pituitary, which appear to have specific endocrine target organs, the hormones of the posterior lobe are more general in action Preparations obtainable from the desiccated posterior lobe cause widespread contraction of involuntary muscle—the oxytocic effect—together with a pressor effect due to vasopressin, which is not antagonised by adrenolytic agents

Progress has now justified the naming of two independent principles Professor du Vigneaud and his colleagues at Cornell [1] have not only succeeded in separating the two hormones—oxytocin and vasopressin—but, by bringing the modern armoury of the protein biochemist to bear, they have shown that the striking contrast in physiological action conceals an unexpected similarity in molecular structure Originally considered to be protein macromolecules, oxytocin and vasopressin have now been shown, by selective enzymic attack followed by chromatography of the fragments, to be polypeptides containing 8 amino acid residues with an approximate molecular weight of 1000 Thus, oxytocin consists of five amino acid residues—cystine, tyrosine, isoleucine, glutamic acid, and aspartic acid—arranged in ring form with a tripeptide tail (prolyl leucyl glycyl amide) attached to the cystine residue This molecule has been synthesised and the product is indistinguishable from natural oxytocin in biological, chemical, and physical properties The synthetic hormone possesses full oxytocic potency and is active in man, stimulating labour and inducing the ejection of preformed milk The structure of vasopressin differs from that of oxytocin only in that the leucine and isoleucine residues of the oxytocin molecule are replaced by phenylalanine and lysine respectively The synthetic polypeptide, without final purification, possesses both pressor and antidiuretic activity

As alternative drugs are available, these pituitary hormones have not found very widespread application, and the new syntheses are unlikely to have much immediate effect on clinical medicine Yet the scientific value of this notable achievement can hardly be overrated The first polypeptide hormones have been synthesised, and perhaps the preparation of synthetic corticotrophin (A C T H) is not as far away as we imagine.

BACTERIAL RECOMBINATION

THE recombination of bacterial cells was discussed by the International Congress of Microbiology in Rome this autumn, and the subject has also been reviewed by Lederberg and Tatum [1] The transference of hereditary characters from one bacterial cell to another was first proved in vivo by Griffith,[2] who changed pneumococcal types by injecting mixtures of types into mice, and Alloway [3] demonstrated that this change also took place in vitro The factors controlling the exchange of capsular types were determined by Avery and his colleagues[4] While this work was in progress Beadle and Tatum[5] demonstrated, in biochemically deficient mutants of the mould neurospora, a form of sexual exchange, and determined the steps by which these organisms synthesise essential foods Turning to bacteria, Tatum and Lederberg [6] showed that a means of genetic exchange existed between mutant strains of bacteria derived from the stock strain of *Escherichia coli* K12 Recombination of these organisms could be detected, because the mutant strains required different essential metabolites for growth, and thus a medium could be designed so that only cells which had exchanged genetic material with cells from a different mutant strain were able to grow Hayes[7] found that in *E coli* mutants resistant to streptomycin the transference of genetic material was unidirectional, one strain acting as the donor cells and the other as the receptor cells Hayes [8] believed that there is only a limited exchange of genetic material, and that the donor cell need not be intact

Two further types of bacteria have been shown to undergo genetic recombination Alexander and Leidy[9], found that a type transference, similar to that seen in pneumococci, occurred in strains of *Hæmophilus influenzæ*, while Zinder and Lederberg [10] discovered a hitherto unknown means of genetic transfer in strains of *Salmonella typhimurium* Here the genetic transfer was apparently due to bacteriophage action, and this type of recombination has been named transduction

From all the evidence it seems probable that both in *E coli* and in *S. typhi* the genes are arranged linearly along one or more chromosomes, but this has not yet been confirmed by cytological studies. In pneumococci and *H influenzæ*, on the other hand, the transforming agent is desoxyribonucleic acid (D.N.A) derived from the type of organism into which the cells are to be changed This change of type by a chemical compound seems a far cry from the sexual fusion of *E coli*, but apparently the gap may be bridged by observations on *S typhi* Here the genetic exchange is due to transfer of material by a phage, although the type of genetic change is similar to that in *E coli* Hershey and Chase [11] have shown that phage infection is due essentially to the entry of the phage D N A into the bacterial cell, hence there is indirect proof that in *S typhi* the essence of transduction is the transference of D N.A from one cell to another Probably, therefore, in all cases the essential material

exchanged is the same and various types of recombination differ only in the methods whereby D.N.A. is transferred from cell to cell

Bacterial transformations have so far been described in few groups of organisms and even then only in certain strains—which suggests that some special character must be present for transformation to take place This may be the loss of a gene by mutation, in pneumococci and *H influenzæ* it is usually only the rough strains that can acquire a new capsule Unfortunately this is not the whole story since new antigenic types can be produced both in *H influenzæ* and *S typhi* and in bacteria there may be dominant and recessive genes

RHEUMATIC FEVER AFTER MITRAL COMMISSUROTOMY

LESIONS suggestive of active rheumatic carditis are sometimes found in the left auricular appendix of patients submitted to mitral valvotomy; and this suggests that rheumatic carditis may continue in a low grade form for a long time, without overt manifestations of rheumatic fever Soloff et al[1] believe that mitral valvotomy may reactivate carditis, they have often observed a clinical picture after valvotomy which they think may indicate active rheumatic infection This syndrome consists in severe precordial pain and fever, commonly accompanied by arrhythmia, cardiac failure and migratory arthritis and occasionally by psychosis The syndrome developed in 43 (24%) of 179 patients who had been subjected to mitral valvotomy and 3 patients died The onset was usually some weeks after operation and after discharge from hospital In addition 4 other patients developed typical rheumatic fever immediately after operation Aschoff bodies in the papillary muscles and inflammatory cells in the parietal pericardium were noted in a patient who died ten days after valvotomy and in whom left auricular biopsy at operation also showed inflammatory cells In most patients who developed the syndrome auricular biopsy revealed changes suggesting activity but surprisingly in the 3 fatal cases only hypertrophy was found Unfortunately necropsy was done in only 1 case, but this showed evidence of active rheumatic carditis It may be thought that changes in the appendix do not represent the rest of the heart but McKeown[2] has shown that Aschoff bodies in the appendix are usually associated with a similar change in the ventricular muscle.

Soloff and his associates[1] were unable to correlate the post valvotomy syndrome with any recent event of active rheumatism with the operative findings, or with the abnormalities in the auricular biopsy Indeed the proportion of positive biopsies was about the same (40%) in patients who did not develop the syndrome as in those who did. The precordial pain which was a constant feature was always severe and was usually localised to the precordium and left lower parasternal area, and was variously described as vice like tight" or "crushing In some cases it radiated to the back the left shoulder and the epigastrium It was aggravated by movement, respiration change of position and even swallowing but was readily relieved by simple analgesics In many cases the heart increased in size and electrocardiography showed ST and T wave changes compatible with pericarditis or myocarditis in addition to increase in the duration of systole and various arrhythmias. Other investigations proved unhelpful and hormone therapy and salicylates were of doubtful value Whether the pain is attributable as Soloff et al imply to rheumatic pericarditis is debatable Severe chest pain is uncommon in rheumatic fever and other possibilities such as postoperative incisional pain coronary occlusion pulmonary embolism or postoperative pericardial effusion must be considered It seems highly probable, however that the arthritis fever sweating and progressive cardiac failure are manifestations of rheumatic infection Soloff and his associates discuss mechanisms by which the rheumatic activity may possibly be induced Operation might permit spread of endogenous streptococci or increase susceptibility to subclinical streptococcal infections; the incision of inflamed tissue might cause the spread of inflammatory agents or the syndrome might be another example of the hypersusceptibility of the rheumatic subject to non specific stimuli. These workers incline to the view that a patient with rheumatic heart-disease has low grade active carditis throughout his life which is usually maintained in relative quiescence by the natural defence mechanisms of the body

In this series the onset of the syndrome in so high a proportion of patients is disquieting and careful observation of all patients after mitral valvotomy is clearly essential Other workers who have reason to suspect active rheumatism after valvotomy should report their experiences in order that the frequency of this complication may be further estimated Soloff et al say that they approve of giving large amounts of salicylates routinely after valvotomy but such a practice may tend to suppress the general manifestation of the disease, and perhaps mask the nature of the important cardiac complications Whether prophylactic chemotherapy to inhibit streptococcal upper respiratory infection should be given to all patients with rheumatic heart disease, especially after valvotomy is another important question which is still unanswered.

PREPARATIONS OF CORTICOTROPHIN

THE preparation of a pure adrenocorticotrophic hormone from the pituitary was first announced almost simultaneously by Li et al[1] and by Sayers et al[2] Extracts have been assayed principally by two methods which depend on different effects of corticotrophin (A.C.T.H.) on the adrenal cortex of the hypophysectomised animal The first measures an increase in adrenal weight[3] and the second, introduced by Sayers et al.,[4] the disappearance of ascorbic acid from the cortex during the production of cortical hormone Results by the two methods may differ widely and in purifying pituitary extracts Dixon et al[5] have been able to produce separate fractions in which the effect on either adrenal weight or on ascorbic acid depletion predominated Thus there may be two pituitary hormones with adrenocorticotrophic effects though the one affecting adrenal weight might in fact be growth hormone.[6]

The international standard by which the preparations of corticotrophin in clinical use are measured is based on an assay by the Sayers technique where corticotrophin is given intravenously It is now clear that different preparations of the hormone which are of similar potency when given intravenously may have different potencies when given subcutaneously or intramuscularly[7] and in general the available preparations are destroyed more rapidly in the muscles than in the blood stream.

Wolfson[8] discusses three main types of preparation which have been compared: the original crude hormone corticotrophin purified twentyfold or fortyfold by absorption on oxycellulose (Astwood); and a product of the hydrolysis of corticotrophin with a moderately low molecular weight which may be a peptide Of these only the purified preparations retain a high potency

when given intramuscularly compared with the potency by the intravenous route The preparations produced by hydrolysis, and also the crude corticotrophin with which we are mainly familiar, undergo fairly rapid destruction when given intramuscularly and the rate of destruction varies in different batches and in different individuals Indeed, patients may acquire the ability to inactivate intramuscular corticotrophin while they remain sensitive to that given intravenously Since the hormone is assayed by an intravenous test and is usually given intramuscularly, it is not surprising that the clinical potency of some batches has appeared to disagree with their label

It is likely that, for intramuscular treatment, purified corticotrophin, made up in gelatin so that it is slowly liberated, will turn out to be the most efficient, though Wolfson has noted an unusual complication of peripheral vasodilatation which produced unpleasant symptoms The ordinary complications of corticotrophin therapy —the result of excessive adrenal stimulation—are of course no more easily avoided than with other preparations

THE MUSICIAN'S MOUTH

SOME of the physical signs peculiar to the professional musician have already been described in a fascinating monograph by Francesco Ronchese[1] Examination of the musician's fingers, hands, and mouth may show changes that are characteristic of the instrument he plays In fact, according to Ronchese, it is possible to distinguish between a musician who plays a 'cello or double-bass in a symphony orchestra, and one who performs in a theatre orchestra or dance band The symphony player has a hardening of the skin on the thumb from the so called "thumb-position" which is used only in the execution of "serious" music None of these callosities on the fingers or hand seems to hamper his playing But the acneiform dermatosis which is occasionally seen under the chins of professional violinists may prove a definite handicap, and so may certain abrasions of the buccal mucous membrane in players of wind instruments—a subject lately discussed by Porter[2] Players of reed instruments often have a characteristic mark on the inner surface of the lower lip, where the lip is compressed between the mouthpiece of the instrument and the lower incisor teeth This condition can be sufficiently painful to interfere with playing and is aggravated by irregularities of the teeth Those who play the flute or piccolo are seldom troubled in this way because of the different embouchure they adopt[3] A different embouchure sometimes used by reed instrumentalists may spare the labial mucosa, but only at the expense of the lower incisors, which are often affected by a pressure osteoclasia The saxophone is responsible for more oral lesions than any other reed instrument because of its weight (which may be as much as 16 lb)—a good deal of which is supported by the lower lip Brass instruments, with their extra oral mouthpieces, can produce lesions on the cutaneous surface of the lips,[1] which may actually perforate[4] Although these mucosal injuries are common, there is little evidence to suggest that there is any tendency towards leukoplakia or malignant change

Porter discusses the various ways in which the dental surgeon can help the musician to enjoy greater comfort in playing—methods that are rather more effective than the time-honoured one of covering the lower teeth with a cigarette paper These methods include smooth acrylic caps for the lower incisors and cast metal splints for incisors loosened by bone absorption Full denture prostheses present special problems of their own, and Porter describes the "embouchure denture" intended to be worn only when playing—an appliance first devised by Reichenbach and Brückl[4]

C S F CHANGES IN POLIOMYELITIS

IN poliomyelitis the changes in the cerebrospinal fluid (C S F) usually follow a well defined pattern similar to that in other neurotropic-virus infections Early in the disease, in the meningeal and *early paralytic stage*, there is pleocytosis with both polymorph and lymphocytic cells and some rise in the protein content If the examination is repeated after a week or so, the cells will be fewer and of lymphocytic type, but the protein may still be increasing, indeed, the picture may later be that of *dissociation cyto-albuminologique*, which at one time was thought to be diagnostic of infective polyneuritis Within this broad framework, however, the cellular response may vary widely from case to case and many of those who see much of poliomyelitis will recall an occasional case where the patient almost certainly had poliomyelitis and yet the C.S.F was normal

Bentzon and Hilden[1] have reported their findings in 97 paralytic and 627 non paralytic cases from the 1950 Copenhagen epidemic Their figures show that the higher the total cell count, the greater the percentage of polymorphs is likely to be In children the number of cells is significantly higher than in adults, in neither is there any significant difference in pleocytosis between paralytic and non paralytic cases, but increase in protein is more distinct in the paralytic cases. They also remark that, allowing for the point in the course of the disease at which the C S F was examined, a strikingly large number of cases in their series had a high total cell count—over 1200 per c mm in 19% and over 2400 per c mm in 6% This may be due to the "antigenic" state of the population at risk, but could also conceivably indicate that a variant form of the virus was responsible for the epidemic—a suggestion that has already been made on other, equally tenuous, grounds

AIR IN THE HEART

THE entry of air into the left side of the heart is a dreaded complication of operations involving a left cardiotomy The increasing scope of such operations[2,3] has stimulated research into the cause of death when air enters the left ventricle

Geoghegan and Lam[4] have made a series of observations on dogs Air in amounts varying from 0·25 to 2 0 c cm per kg body-weight was injected rapidly into the common carotid arteries after thoracotomy, and the aortic blood-pressure was recorded by an impedance manometer No impairment of cardiac function or fall in aortic pressure occurred, but signs of neurological damage developed It was concluded that cerebral air-embolism was probably not the cause of sudden death in similar clinical circumstances A further series of experiments was done to determine whether a compressible mass of air in the left ventricle would embarrass the heart in the absence of air in the coronary arterial system In a number of dogs the heart was exposed and a balloon placed in the left ventricle and inflated with air Records of aortic pressure showed little or no change, the left ventricle apparently compensated for the reduction in volume produced by the balloon After removal of the air from the balloon, the same amount of air was injected into the ventricular cavity In a few moments the heart became cyanotic, the aortic pressure fell sharply, and in animals receiving 1 5 c cm of air per kg ventricular fibrillation or asystole and death, rapidly followed rapid aspiration of air

from the ventricle was of no value At necropsy most of the coronary tree was seen to contain air In dogs which survived a smaller injection of air the aortic pressure rose as the air passed into the periphery of the coronary arterial system

The mechanism by which air in the coronary arteries produces ischæmia of the heart is of interest. Geoghegan and Lam observed that while the proximal end of a column of air in a coronary artery moved with each ventricular contraction the distal end remained stationary The propulsive force of the column of blood was damped out by air compression, so that the coronary circulation was virtually arrested Since air which had been injected into the left ventricle was collected from the coronary sinus it must have passed through the capillaries

This being so resuscitation might be possible if the air could be propelled rapidly enough through the coronary tree With this in mind the same workers devised a further series of ingenious experiments After the injection of air into the ventricular cavity, the aortic pressure was raised by clamping the aorta distal to the left subclavian artery, thus raising the pressure in the proximal aorta Cardiac massage was then started; and as the air was displaced into the smaller branches of the coronary arteries the main ventricular mass changed from a cyanotic to a bright pink colour and the heart regained its contractile force This produced a second filling of the coronary arteries with air which had been trapped in the ventricular cavity after the initial injection Elevation of the cardiac apex and aspiration of the cavity just before aortic occlusion were found to reduce this refilling By these manœuvres, 17 out of 20 dogs were resuscitated after the injection of amounts of air which would otherwise have been fatal Electrocardiograms of these animals became completely normal, and no residual cerebral damage was found

The entry of air into the coronary arteries is a hazard of all operations on the left side of the heart. It will reassure the surgeon to know that, should this disaster happen, clamping of the aorta vigorous cardiac massage, and aspiration of air from the left ventricle may empty the coronary tree of air quickly enough for the patient to recover completely

CHEMOTHERAPY IN PNEUMONIA

THERE have been few attempts to assess from large numbers of case records, what modern chemotherapy has done for the patient with pneumonia In 1942, during the heyday of the sulphonamides Stable[1] in Pennsylvania, reviewed 15 000 cases and showed that since the introduction of sulphonamides the mortality from pneumonia had fallen from over 30% to less than 10% Now Norris[2] has studied a series of 8000 cases at the Dudley Road Hospital, Birmingham and she has reached some interesting conclusions. Her figures are based on the hospital's diagnostic index and case notes She compared the results of treatment in the years just before the introduction of chemotherapy (1934–38) with those obtained ten years later (1944–48) The mortality from lobar pneumonia she found, was reduced from over 20% to less than 10% but in bronchopneumonia the death rate was almost unaltered The length of stay in hospital was reduced by from four to six days—the exact figure varied with the patient's sex and the type of pneumonia. This represented an annual saving of 2500 bed-days, thus releasing in the one hospital from which these figures were drawn seven beds each year for the treatment of other diseases. The incidence of empyema as a complication of lobar pneumonia was reduced, in the era of chemotherapy from over 4% to less than 1% but the incidence of serous effusions had correspondingly increased Thus, chemotherapy does not prevent the pleural complications of pneumonia but it stops the serous effusion from progressing to an empyema It is good to see what must be a universal clinical impression put on a sound statistical foundation

Norris also compared the effects of sulphonamides and penicillin In male patients she found nothing to choose between them but among women those on sulphonamides apparently did better than those on penicillin It seems on the face of it unlikely that there can be a sex difference in the response of patients to antibiotics, but this may be a point that requires further investigation This confirmation that, in general penicillin may be no better than sulphonamides, which are cheaper and more convenient is also of interest because of the widely held view that the patient who needs to be admitted to hospital for pneumonia does so because he has failed to respond to sulphonamides at home.

The conclusions reached in this inquiry may be faulted by some critics because they have not been obtained by methods which would satisfy the stringent criteria for a controlled therapeutic trial They are none the less of great interest because they are the results of the study of ordinary hospital records and there is a great deal of medical information which must be obtained in this way or not at all

RENAL FUNCTION AFTER UNILATERAL ADRENALECTOMY

ALTHOUGH the adrenal glands owe their name to their position their close proximity to the kidneys has seldom been considered relevant to the important action which they exert on the renal conservation of salt A few reports have indicated that unilateral adrenalectomy may be followed by an increased excretion of salt and water by the kidney on the operated side[1 2] but this has usually been ascribed to incidental damage to the renal nerve supply on that side with release of vasoconstrictor action on the renal vessels, and a consequent increase in filtration rate[3] Simple section of the nerves to one kidney has indeed been followed by an increased excretion of salt by that kidney in comparison with the other kidney[4] and this was shown to be independent of change in glomerular filtration rate so that the change in renal performance was attributed to loss of splanchnic control of tubular activity Although there is good evidence of a nerve-supply to the renal tubule cells[5] the results of splanchnic section might equally well affect the adrenal gland rather than the kidneys themselves

Dempster and Graber[6] now report an interesting series of experiments on dogs, which suggest that removal of one adrenal gland may induce a salt and water diuresis in the kidney on that side, independent of any damage to nerve supply to the kidney or change in filtration rate Urine was collected by catheter directly from the two ureters, and, in control dogs, specific gravity rate of chloride excretion and clearances of creatinine and p-aminohippurate were not much different on the two sides. Such differences as there were bore a relation to the weights of the respective kidneys the ratio of glomerular filtration rate to kidney weight on the two sides was very similar even when the absolute filtration rate was different in the two kidneys When one adrenal had been removed and sodium chloride was infused, the kidney on that side excreted chloride several times more rapidly than its companion without any corresponding deviation in glomerular filtration rate when the weight of the two kidneys was taken into account. This chloruresis was absent in two dogs which were studied

days after adrenalectomy, but present in six dogs tudied at 6, 8, 12, 25, 60 and 90 days after the operation. our dogs were subjected to "mock adrenalectomy," n which one adrenal gland was dissected free as for emoval, but then left in its bed; three of these dogs howed chloruresis, the fourth did not. The possibility of ocal spread of material from the adrenal to the kidney was xamined by injecting indian ink into the adrenal gland. he ink diffused into the pelvic fat and lymphatics of the enal capsule, but not actually into the renal parenchyma.

Taken in *conjunction with previous* work, these experinents suggest that direct infiltration of the kidney by drenal steroids may be more significant than the ircuitous path through the greater and lesser circulations hich is the proper route for a hormone; otherwise, it s difficult to see why the opposite intact adrenal did not ontrol the behaviour of both kidneys. The chain of vidence is not quite firm, and the chloruresis after nock adrenalectomy needs explanation, unless it is ssumed that the mere process of dissection damaged he gland. Damage to nerves is admitted, but the latent eriod before chloruresis appeared makes it unlikely hat nerve damage was responsible. Studies on potassiumxcretion in similar circumstances would be worth naking, since a fall in potassium output, concurrently vith the chloruresis, would strengthen the likelihood of n adrenal hormone being responsible. Now that a otent adrenal mineralocorticoid has been detected[7] nd isolated by Reichstein,[8] it might even become ossible to see whether topical application of this subtance would influence renal function. The matter is orth pursuing, quite apart from its general biological nterest, for it may have some relevance to the distant oal of renal transplantation, even although it does not ccount fully for the hyposthenuria of a kidney autoransplanted into the neck.[9]

BACTERIA AT SEA

THE survival in natural waters of bacteria derived rom human excreta has been the subject of inquiry ince the dawn of bacteriology. We know that few of hese survive for long; but in the mechanism of selfurification the relative shares of time, light, oxygen, acteriophage, and other factors, known and unknown, re obscure. The results of investigations are seldom in greement. Even under the strictly controlled conditions f modern experiment it has been found that the "fæcal oli" in water may increase or decrease by 50% after torage in the laboratory for 24 hours[10]; and if this appens in the sterilised bottle it is obviously difficult to orecast what may happen in the stagnant pond or urling brook. For obvious reasons less attention has een paid to the survival of these bacteria in sea-water. he volume of sewage which enters the sea would seem lmost literally a drop in the ocean, and it is easy to be ersuaded that this dilution, together with the summer un and the movement of the tides, robs seabathing of ny perils of infection. Yet the risks may be greater than e realise. Empty a bottle, recork it, and cast it far into our favourite cove in calm weather; if it is not floating here several days later you will probably find it on the trand. The amount of crude sewage which is deposited n the popular beaches of the Lancashire coast is said o be not less than 100 gallons per yard of foreshore per ay[11]; and it is not unknown for a municipal swimmingath to draw its water at high tide from some murky orner of a commercial harbour. It is true that direct vidence of enteric infection acquired while bathing is neagre, but this is not the only way that infection may come from salt water. An epidemic of paratyphoid fever in Germany was traced, not to bathing in the harbour, whose waters were shown to contain the responsible organism, but to eating fish which had been landed and "cleaned" in the harbour.[12] Oysters are supposed traditionally, if erroneously, to prosper best on a diet of diluted sewage, and of their part in spreading enteric infections there is no doubt.[13]

Recently this subject has aroused interest in France. A committee of bacteriologists has confirmed that fæcal organisms as a whole are quickly destroyed in sea water and attribute this to a *pouvoir antibiotique* rather than to bacteriophage.[14] They found that this disinfectant property was absent from boiled sea water and "synthetic sea water" and was increased by oxygenation; it was more apparent in water from the Channel than in that from the Mediterranean. But Buttiaux,[15] who has added much to our knowledge of the bacteriology of water, inoculated several species of salmonella into samples of sea water *obtained* several miles off-shore and found that about half of them survived for 24 hours at room-temperature, whereas in fresh water under identical conditions only 1 in every 1000 survived. *Salmonella typhi* appeared to have the shortest life of the salmonella tested, but apparently only one strain of each species was used. It is a pity, too, that some species of bacterium (or perhaps we should *now* say escherichia[16]) was not used in these experiments; usually this genus and salmonella behave similarly in an inimical environment.

If salmonella does survive for any length of time in sea-water, how important is this? If they last much longer than bacterium we shall have to change our methods of examining the water. But will the careful paterfamilias forbid immersion to his young and keep them digging and sandcastles beside his deck-chair? Not, we hope, in the bicentenary year of Dr Russel of Brighton. If sharks do not deter the Australians, salmonella should not keep us out of the water. *Outbreaks* of enteric infection are not uncommon at seaside resorts and have usually been shown to be due to shellfish, food and drink of dubious quality served by even more dubious hands, or sometimes to the happy go lucky way of living which suits many on holiday. Now that an open-air holiday has become modish, most of those places where tents and caravans gather together enjoy reasonable water supplies and sanitation—thanks to the foresight of the local authorities. It would be a good thing if they all did. It seems, however, that the danger is greater from disposal of sewage by methods *adopted* long before the beaches became as popular as they are today. A pool of sewage dripping from an exposed pipe and washed away (in theory) at every high tide is a poor ornament to any plage. Indeed it is high time that everyone (including some of our largest municipal corporations) realised that to pour untreated sewage into the sea is as *out of date as the* traditional Edinburgh custom of emptying the chamber-pot out of the window—and far more dangerous.

WE regret to record the death of Sir LANCELOT BARRINGTON-WARD, consulting surgeon at Great Ormond Street, and of Mr B C MAYBURY, consulting surgeon to St Thomas's Hospital.

AT the first annual meeting of the College of General Practitioners reported on p 1087, Dr WILLIAM PICKLES was elected to the presidency.

A CHAIR of rheumatology has been established at the University of Manchester with the financial support of the Empire Rheumatism Council. Dr J H. KELLGREN has been appointed its first holder, from Dec. 25.

COLLEGE OF GENERAL PRACTITIONERS

FIRST ANNUAL MEETING AND FIRST PRESIDENT

THE first annual general meeting of this college held in London in the great hall of B.M A House last Saturday was attended by 400–500 members and associates from all parts of the British Isles and Eire

Dr G F ABERCROMBIE chairman of the foundation council, in moving the adoption of the annual report said that on Nov 10, 1952, when the steering committee was dissolved the ten general practitioner members of that committee had to decide what was to be done next Two courses were open to them (1) to publish the committee's report and wait and see what happened or (2) to found a college at once Believing that if they did nothing then nothing would be done, they resolved to found the college and now, before a year had passed it had been joined by more than 2500 men and women The majority of these were in England, about 300 in Scotland over 100 in Wales and nearly 100 in Northern Ireland substantial contingents came also from Eire Australia, South Africa, and New Zealand and others from widely separated places all over the world A council of the college in Scotland had been set up to deal with Scottish affairs. Telegrams of greeting had just been received from New South Wales and from New Zealand telling of faculties of the college founded there and also one from Canada (from Dr M R Stalker) which said :

"On behalf of the organising committee of the College of General Practice of Canada I wish to extend to you our greetings at this your first Annual Meeting The leadership of your College has been of great assistance to us and we hope to have the Canadian College founded in 1954

The college, Dr Abercrombie said had taken no part in medical politics during the past year and consequently though in contact with many organisations, was in collision with none

After giving an outline of the work of the committees on undergraduate education, on postgraduate education and regional organisation, and on research[1] and of the other activities of the first year Dr Abercrombie ended by saying that the hopes of the founders would be fulfilled only if every member and associate did something for the college. If a request for help from student or practitioner was never to be refused everyone must take a share the steadily increasing burden could not be borne indefinitely on the shoulders of a devoted few The future of the college and with it something of value to the future of British medicine was not in the lap of the gods ; it was in the hands of every member and every associate He announced that the foundation council had presented to the college a Foundation Council Medal to be awarded from time to time by the council of the college for work of the highest merit in the realm of general practice or for services of the greatest distinction to the cause of general practice

In proposing Dr William Pickles of Aysgarth Yorkshire, as first president of the college, Dr J H HUNT hon. secretary of the foundation council said that the foundation council had been conscious from the beginning that it was to a great extent a self-elected body ; and because of this it was hoped that the first president would be someone who had not been a member of this council and who had not been directly connected with the foundation. It was common knowledge that Dr Pickles had done a great deal for British medicine Many practitioners before him including William Budd and James Mackenzie had retired from family doctoring when they became well known But Dr Pickles had absolutely refused to abandon his practice in spite of several temptations throughout the years He would always be admired not only for his original work but also for the unshakeable stand he had made throughout his life for general practice and for general practitioners. Dr F M ROSE (Preston) described Dr Pickles as the doyen of general practitioners in this country his wisdom would be of great service to the college and in honouring him the college would be honouring itself Dr Pickles was then unanimously elected to the presidency

Dr PICKLES said he felt sure that the great general practitioners of the past would have approved of the foundation of this college He was confident that there was no-one present in the hall who did not look upon this as a historic occasion probably one of the most momentous in the whole long history of general practice

The Greek Ambassador M. BASILE MOSTRAS, then handed the president a gift—a gavel made from the wood of an ancient plane tree from the Island of Cos the home of Hippocrates In thanking His Excellency the PRESIDENT said that this gift was a token of the friendship between the two nations and was a reminder of all that Greece had done for the honour no less than for the art and science of medicine It seemed most appropriate that the first treasure of the new college should be a gavel from the birthplace of scientific medicine Dr G I WATSON proposed a vote of thanks which was given with acclamation.

Before the election of the first college council its constitution was discussed

The foundation council it was stated had been particularly anxious that every doctor in the Provinces should feel himself adequately represented, through his regional faculty on the first college council. Dr A BROWN (Cambridge) proposed that the new council should consist of 25 members, but a counter proposal of 20 members was carried by a show of hands. It was agreed that these 20 members should be elected to the council that afternoon As it was desirable that each regional faculty should be represented on the council by at least 1 member of the faculty the council was authorised and requested to make from time to time after consultation with the board of the faculty concerned, such additional appointments as might be necessary to secure or maintain this representation.

In the ballot, out of 37 names put forward the 20 members of the foundation council who had submitted themselves for re-election were re-elected They are :

G F Abercrombie (chairman) F M Rose (vice-chairman) H L Glyn Hughes (hon treasurer) J H Hunt (hon. secretary) G O Barber John Cottrell, D G French Annis Gillie I D Grant, J M Henderson, W V Howells R M S McConaghey J G Ollerenshaw R J F H Pinsent A Talbot Rogers Richard Scott Andrew Smith George Swift G I Watson and J Campbell Young

The first college council thus consists of 4 members from London 3 from Scotland 1 from Wales, 1 from Northern Ireland and 11 from the English counties. To these will be added representatives from all those faculties both at home and overseas which are not already adequately represented

The constitution of the college was reviewed and the by laws were confirmed with two small amendments. It was agreed that a model for the regional faculty boards was necessary ; but the meeting accepted an amendment, proposed by Dr W W FULTON (Glasgow) to allow each faculty scope for development along lines best suited to its local needs

The feeling of the meeting was summed up by Dr ROSE when he said We are here not because we think we are good practitioners but because we want to be better ones.

Public Health

Poliomyelitis in Canada

THERE have been nearly 2300 cases of poliomyelitis in Manitoba this year[1]—the second successive year in which there has been a serious epidemic in the province The attack rate of 1 in 330 was unusually high and the proportion of paralytic cases was greater than expected Of all those affected 62 % had paralysis and of those over the age of 20 30 % were paralysed In spite of this the death rate was less than 4 %. 6000 persons were inoculated with gamma globulin : there were 40 cases of poliomyelitis in this group but in 36 of these the illness began within seven days of inoculation Another feature of the epidemic was that there were relatively few cases among children in areas where sanitation was poor

The Wider World

THE YUKON TERRITORY

A ROTHWELL
M.A , M B Camb , D C H

EVEN in Canada it is by no means easy to get useful information about the Yukon In the larger towns most people have only heard of the place, and know nothing about it. Indeed, many think that it belongs to the United States and is part of Alaska Workmen who have been there can seldom convey an idea of what it is really like Much of the material to be found in libraries is not up to date, for conditions are changing rapidly

* * *

This part of Canada, roughly triangular in shape, lies entirely to the North of latitude 60° N , which is its boundary with the Province of British Columbia To the West is Alaska, which is part of the United States, and to the East stretch the Northwest Territories of Canada The Yukon itself is a plateau with the watershed of the Ogilvie Range of the Mackenzie Mountains lying roughly transversely to the North of its central portion, and it is crossed by valleys whose bottoms are filled with muskeg from which the rivers drain, and where good fishing is to be had The hillsides are surprisingly well wooded, except where the trees have been destroyed by forest fires or have been cut by loggers for timber or by woodcutters for fuel Scrub poplar, birch, and willow, and several sorts of spruce and pine, are to be found There is so much sunshine during the short summer that many wild flowers grow to amazing size, and excellent raspberries, blueberries, and cranberries abound The woods and scrub are full of small animals, especially squirrels, and big game such as moose and bear may be met

The very pleasant summer lasts from sometime in June until sometime in September , the between-seasons of thaw and freeze may last from four to six weeks each , the rest of the year is winter The winter is cold Snag, in the West of the Yukon, is reputed to be the coldest place in all Canada, with temperatures sometimes 80° below zero Fahrenheit or even lower In many parts of the territory temperatures 60° below zero are not uncommon There is not much snow , the rainfall is slight , so on the whole the climate is dry But there is enough water to fill the rivers that flow into the Yukon—the local Indian word for " Greatest River "

* * *

The country was first travelled by officers of the Hudson's Bay Company who were interested in the fur trade and who established trading posts Owing to the lawlessness prevailing when the mines were being developed during the last decade of the 19th century, the Yukon in 1895 became a district of the Northwest Territories under an inspector of the Northwest Mounted Police The Yukon Act of the Canadian parliament created the separate Territory in 1898, to be administered by a commissioner appointed by the Dominion government itself In effect, the Yukon Territory is a dependency or colony of Canada

Dawson City of Klondike fame, the former capital, is steadily decaying despite considerable seasonal production of gold by the dredgers each summer An increasing number of sightseers are attracted to it by the reputation of the fabulously wicked city of fifty years ago Indeed, Discovery Day, Aug 20, is still the most important bank holiday of the Yukon Territory Whitehorse, the new capital, is now the big town, and more than half of the Yukon's population of 10,000 live there It is the chief town of the Alaska Highway which is doing much to open up a territory of more than 200,000 sq miles f future development A small and inconvenient railw which is fast approaching its maximum carrying capacit connects it with the Alaskan port of Skagway and has a large and growing airport About the centre of t territory is a base metal mining area which is bei actively explored for further ores of value, and whi therefore has a rising population

* * *

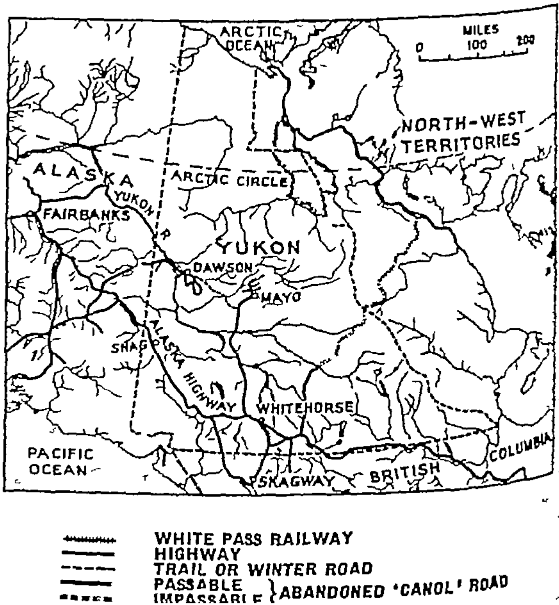
For communication with the world outside, this centr area used to rely on stern-wheel paddle steamers plyi the Yukon and its tributaries, and pushing barges befo them during the short season of navigation from la June to early October But this method of carryi traffic was slow, cumbersome, costly in damage and losses, uncertain, and therefore very expensive. Duri the winter one might travel with a dog team and sledg Nowadays aircraft carry more and more of the passenge mail, and goods About three years ago a new road w constructed from Whitehorse to Mayo Landing, abo 350 miles in summer there are powerful ferries at t three big river crossings, and in winter one travels alo a good snow road with well-maintained ice bridges B even this road cannot be used during the four to s weeks of break-up in spring, and the similar period freeze-up in early winter

Prices are still high petrol in Whitehorse costs abo a third more than in Edmonton, and at the more isolate distribution points about double the Edmonton pric Other kinds of goods, including food and spares of a kinds, which " come in " from the outside world are al expensive The local idiom is still to " come in " t and to "go out" from, this area so recently opened t modern travel

* * *

A few old-timers of sterling worth have survived fro the days of the Klondike gold rush that put this part o the world on the map In their old age many of the men are in comfortable circumstances, having sold mini claims of considerable potential value in view of th importance of lead compounds in increasing the efficien of petrol They tell amazing stories of the stirring time of fifty or sixty years ago

There are also many alcoholics Generally they ar younger than the genuine old timers, whom they out number Either the environment is favourable to th development of this disability, or sufferers and potenti



sufferers gather in the land and fail to move out again Other misfits of society are also prominent, such as those who have failed to get on with wife or family, or who have got on too well with somebody else's wife. Many men suffer from lack of success elsewhere or are of plainly inadequate personality They may have exhausted their social benefit, and then have drifted via "skid row" (the place of the down-and-out of Canada) to be hired for some construction or mining task in the North These men work unhappily and incompetently until they lose their jobs or have enough money to go on holiday again They are numerous and their lot is made no easier by the men who supervise them, who are no doubt competent in their own skilled occupations, but who lack the understanding that is necessary to make a success of handling poor human material The quality of this labour the way it is handled, and the effects of the consumption of too much liquor over short periods and long, together make the most difficult problem of the present day The solution is neither apparent nor apparently being sought

On the other hand wages are high and a man may make a "stake" in dollars that will enable him to lay the foundation of success elsewhere. Even the labourer may do this. The skilled workman may more readily succeed because of the lack of skilled men Some of this group have come to the Yukon and discovered a love for the North country that holds them there with the prospect of long enjoyment, and these men will be the excellent old timers of the future

* * *

In the whole of the Yukon three or four doctors practise, and the Services have their own medical staff in Whitehorse and along the Alaska Highway When there was no civilian dentist in the region people might go to Edmonton or Vancouver each about 1700 miles away, for dentures and dental repairs But recently a dentist has come into the Yukon with a large caravan that is his mobile surgery to travel the highway in season Whitehorse has a hospital, and there are small hospitals equipped according to their size and situation in the two other populated places. Thus the way of life of a doctor in the Yukon is indeed general practice, and his results depend in no small degree upon the stuff of which his patients are made There is even some State medicine for the Indians are wards of the Dominion government which pays the doctor a fee for each service on their behalf. These Indians are good patients most of them fully cooperative in their treatment and appreciative of the attention which they receive But history taking may be difficult when the patient is a man of few words and little English.

The officer appointed by the Dominion government to look after the interests of the Indians is the Indian Agent and he is a fine friendly humane welfare worker, doing a job well that is far from easy to do The other social worker for the populace is the Mountie for the Royal Canadian Mounted Police are the successors of the Northwest Mounted Police of the turn of the century Serious crime fortunately is not common From time to time a vehicle may go off the road, an aircraft may become overdue, an old timer living in some remote place may receive a visit and the alcoholic may finally drink himself to death

The pattern of disease is not unlike that in Britain today The exceptions are impetigo which is common and hypertension, which is rare Many elderly men still live in the cabins that they and their partners built many years ago so perhaps the potential hypertensive does not survive in these surroundings, or perhaps the soil lacks the hypertensive factor! Deficiency diseases are rare in the present prosperity for most of the transients are fed by their employers, and the permanent residents know how to look after themselves from long experience One trapper of my acquaintance, a stalwart Yugoslav widower, disappears each October until the following June and lives alone at the end of a distant lake upon the wildlife of the country, with the help of evaporated milk and tea But he takes a thousand tablets of ascorbic acid as part of his regular stores, for even recently the knowledge that the bachelor was more prone to deficiency diseases than the man who was not unaccompanied was associated with the belief that a man could prevent scurvy by taking a squaw

* * *

This Yukon Territory is the Land of Winter where old King Zero reigns supreme for the greater part of the year The dryness and the stillness of the air contrast with the damp cold winter of the British Isles where the weather is much more stormy A log cabin warmed by a wood burning Yukon stove can be very snug Mukluks upon the feet in as many layers of Moose hide as may be needed keep out the cold as efficiently as lined flight boots and are even more comfortable but the skin must be kept dry by well ventilated clothing for sweat freezes readily and leads to frostbite It is a fabulous country, as its own chronicler Robert W Service, has made clear

Medicine and the Law

Spinal Anæsthesia

AFTER a hearing lasting eleven days allegations of negligence in the administration of spinal anæsthetics were dismissed on Nov 12 in a reserved judgment by Mr Justice McNair[1] Two labourers were admitted to the Chesterfield and North Derbyshire Royal Hospital for minor operations six years ago In both cases Nupercaine was injected intrathecally on the same day As a result each of the men had the same symptoms their conditions pursued much the same course and both became permanently paralysed. They sued the Ministry of Health (as trustees of the hospital) and the visiting anæsthetist, alleging negligence or unskilfulness in the administering of the anæsthetic they also sued the company which manufactured the nupercaine alleging that it had negligently permitted a harmful substance or irritant to be present in the anæsthetic or in the ampoule At the close of the plaintiffs' case the manufacturers were dismissed from the action it being agreed that the company was not legally liable. An eminent witness for the plaintiffs had accepted in cross examination a suggestion that nupercaine was as good a spinal anæsthetic as you can get.

The court had to decide if it could between some conflicting medical evidence on the cause of the plaintiffs paraplegia It had to determine the legal responsibility of the Ministry, the anæsthetist and the hospital staff in relation to one another and it had to deal with the plaintiffs contention that the facts spoke for themselves (in the forensic phrase *res ipsa loquitur*) in such a way as to impose upon the defendants the burden of proving that they had not been negligent thus displacing the normal duty of plaintiffs to establish their allegations It must have been an important element in the case that standards of anæsthesia applied in 1947 could not be expected to take account of later theory or research Mr Justice McNair was satisfied that the method of injecting nupercaine by lumbar puncture was widely practised in 1947 before the development of other relaxant drugs No charge of negligence he said was based on the adoption of this method for the two operations in question

---

[1] *Times* Nov 13 1953.

The learned judge found himself bound by the rulings n Gold *v* Essex County Council (1942)[2] and Cassidy *v* Ministry of Health (1951),[3] and thus he held that, so far s the anæsthetist was concerned, the hospital's obligation owards the plaintiffs as patients was no higher than the uty (which it had performed) to appoint a competent næsthetist The hospital was not liable in law for his cts of negligence (if any) As for members of the theatre taff, the hospital must assume the vicarious liability of a master for his servants The anæsthetist was a visiting pecialist, comparable to a visiting surgeon or physician or whose acts the hospital would not assume liability The legal maxim *res ipsa loquitur* could not apply where he criticised thing or operation was under the control of wo parties not in law responsible to each other , if what had happened spoke of negligence, it did not speak against ither party individually The evidence had shown, moreover, that, although the anæsthetist was responsible or choosing the anæsthetic, for directing its preparation, nd for generally supervising the activities of members of the theatre staff, he must not be deemed responsible or their casual acts of negligence In consequence, in the udge's view, the normal onus rested on the plaintiffs of proving negligence on the part of the hospital or the næsthetist

What, then, caused the plaintiffs' unfortunate disabilities ? The court remarked that it had been conceded that the injection of nupercaine was not negligent , the medical evidence " clearly established " that the injuries were not caused by an infective organism or by damage to the spinal column produced by the needle The glass ampoules containing the nupercaine had been stored in a 1 in 40 phenol solution, after temporary immersion in a 1 in 20 solution Phenol was the only source of contamination which had been suggested The fact that the same substance was injected by the same anæsthetist on the same day into two patients who suffered the same injuries was something which " seemed to point conclusively to some common factor " The proportion of such injuries after such injections seemed to be 1 in 10,000 The court found it difficult to ascribe to some personal idiosyncrasy on the part of the patient an injury so rare when the common factor was present in the case of these two plaintiffs Glass ampoules could crack , if they did, nupercaine might be replaced by phenol without being noticed In the judge's view, phenol was the most likely common factor , " after the most anxious consideration of the medical evidence " he came to the conclusion that the injuries were caused by the injection of phenol with the nupercaine The phenol could find its way into an ampoule stored in a solution through cracks which the eye could not detect or through molecular flaws in the glass The attention of the profession had been drawn to this risk by Professor Macintosh's book on Lumbar Puncture and Spinal Anæsthesia This book had been published here in 1951 , in 1947 the general run of competent anæsthetists would not have appreciated the risk His Lordship held accordingly that the defendant anæsthetist was not negligent in failing to appreciate it *A fortiori* the theatre staff were not negligent No confident medical opinion could be expressed as to the quantity of phenol necessary to produce the results in question The judge found it difficult to believe that this anæsthetist would have failed to notice a visible crack in an ampoule It had not been shown that the hospital staff had been negligent in handling the ampoules so as to cause invisible cracks As a result of these conclusions the claim must be dismissed both against the hospital and against the anæsthetist

To cite isolated passages from the evidence given by distinguished medical witnesses in a long case is less than satisfactory It may perhaps be mentioned, however, that Prof R R Macintosh, consulting anæsthetist to the United Oxford Hospitals, called by the plaintiffs, stated in cross-examination that he thought their injuries were due to the introduction of phenol into the spinal canal and, asked if there was not a widespread body of opinion that spinal anæsthetics caused these injuries, quite apart from any foreign influence, he replied that he did not hold that view Prof E B C Hughes, professor of neurosurgery in the University of Birmingham, stated that in 1947 an anæsthetist should have known that a normal dose of spinal anæsthetic was dangerous and involved the risk of permanent injury Sir Francis Walshe, F.R.S , consulting physician to University College Hospital, called by the defence, thought that the plaintiffs' paraplegia could not be explained by the introduction of phenol , phenol could not produce such conditions Dr Macdonald Critchley, senior neurologist to King's College Hospital, did not think the injuries were due to phenol , he attributed them directly to the spinal anæsthetic He considered it was high time that the whole problem of the complications of spinal anæsthesia was re examined by the medical profession

Parliament

Dearer Food

In the concluding stage of the debate on the Address in the House of Commons on Nov 10, Dr EDITH SUMMERSKILL moved an amendment deploring the omission from the Gracious Speech of any reference to the high cost of food " which is bearing so heavily on households with small incomes, and particularly on the old-age pensioners " The Minister of Food had made the astonishing admission that he could not forecast how high prices of food would go under derationing Parliament should be told what controls were to be imposed on food in order that the expensive food, the protein body-building food, should be within reach of the poorest Last winter was the first winter for many years in which old-age pensioners were unable, because of the price, to take up some of the foods which gave them a resistance against colds, coughs, bronchitis, and pneumonia , and at the same time, there was a striking increase in the death-rate

If the Government had no plan for controlling prices, she feared that slowly but surely the pattern of the feeding of the poorest people would come to resemble that of the 1930s which was deficient in meat, bacon, eggs, cheese, and milk The price of all these foods had risen She foresaw that in the home the main wage-earner would be fed, but the adolescents, with their big appetites, would be given a taste of these protein foods and their plates filled up with bread and potatoes, neither of which assisted growth or protected people from disease To ration our available food at a price all could afford, she affirmed, was not a sign of weakness but of that strength of character which was the hallmark of the British people

Major GWILYM LLOYD GEORGE, Minister of Food, declared that food questions could not be dealt with in isolation from other economic problems The greatest service which any Government could give to the community, including those who lived on small incomes, was to strengthen the national economy Two years ago the country was heading for bankruptcy, and all the subsidies and all the rationing in the world could not have prevented disaster without a change of policy A good beginning had been made and the steep rises in the cost of living generally, and in food prices in particular, had been slowed down The reduction of subsidies was a necessary prerequisite for derationing and decontrol which had the overwhelming support of the majority of the people in the country He claimed that the Government's policy of removing restrictions and controls was enabling the public to buy the food they wanted at prices which were becoming more stable than at any time since the war

He did not underestimate the real difficulties of pensioners and people living on small fixed incomes, but the Government last year had raised benefits and pensions rates by 25%. The National Food Survey showed that poorer households and old age pensioners were spending about the same on rationed foods as all other groups Apart from meat and bacon the take-up by old-age pensioners of all other basic foods was about 100%. Their consumption of liquid milk was higher than at any time since 1950 Nearly 33% of national expenditure went on food compared with 30% before the war and 15% went on drink and tobacco against 10% before the war To restore the food subsidies to the level of 1951 would mean subsidies approaching £600 million a year or £500 million more than at present. Where he asked was the money to come from ?

Cleaner Food

The Food and Drugs Amendment Bill, introduced in the House of Lords on Nov 10 extends the powers given under the 1938 Act. The Bill gives the Minister of Food power to require the registration of a wide range of premises, including butchers shops and public houses and the licensing of hawkers and of people who sell food from barrows and stalls. The requirements for registration will be laid down by regulation, and will deal with the construction equipment, and cleanliness of the premises.

The new Bill also provides for the control of the use, in the manufacture of food, of substances which might, if taken over a long period be injurious to health Manufacturers will be required to supply information about the substances they use and regulations can be laid down providing that certain substances shall not be used at all, or shall only be used under a certain strength It will also be possible to control processes which although using otherwise innocuous substances, might injure health The Bill puts on a permanent basis wartime regulations on the labelling and advertising of food and extends them to apply to drugs.

The Ministers of Agriculture and Health are to be given powers to regulate the composition of milk sold under specified descriptions to prohibit the sale of milk from cattle in markets and shows and to require such milk to be stained for identification Port health authorities and food and drug authorities will be empowered to restrict the movement of imported food Other powers will enable the disposal of meat unfit for human consumption to be controlled more effectively

Myxomatosis

In the debate on food and agriculture in the House of Lords on Nov 11, Lord RENNELL deprecated the Ministry of Agriculture s efforts to control the outbreak of myxomatosis in south-east Kent. Was it reasonable, he asked, to protect rabbits against a disease that was going to kill them when we were suffering from their depredations on wheat alone to the extent of nearly £5 million worth of valuable food ? If it was not humane to kill rabbits by a disease was it not also equally inhumane to kill rats with phosphorus ? So far as he knew this disease had infected no other animal of any sort in Australia, whether wild or domestic. Why should we spend our money to make British farming safe for rabbits ?

In his reply Lord CARRINGTON suggested that Lord Rennell s arguments, though they sounded forceful were over-simplified Lord Rennell argued that myxomatosis killed rabbits ; rabbits were a pest therefore myxomatosis must be a good thing But there were other considerations to be taken into account before we decided what to do about this disease It was by no means certain that it would be an unmixed blessing To mention only one consideration the disease caused acute suffering to rabbits, and we could not disregard the humanitarian aspect. Also although the disease appeared to affect only rabbits and to some extent, hares, it was a virus disease and we should surely be unwise to allow a new virus disease to become established in this country without first trying to find out as much as we could about it. The virus affected also of course, tame rabbits. The results of the spread of the disease in Australia and France had, Lord Carrington agreed been spectacular but the final results in either country could not yet be definitely assessed In Australia rabbits were now beginning to appear which were immune to the disease As the rabbit population had been so drastically reduced there would be plenty of food for these immune rabbits to eat. They might well multiply quickly with the result that the Australians would be back where they started with the rabbits and with the disease.

The Minister could see the possible advantage if this disease were to wipe out all the rabbits but he had decided that the problem must be considered carefully and systematically before he could commit himself to a line of action which might have far-reaching consequences He and the Secretary of State for Scotland had therefore set up a committee to consider the problem At the same time the Minister had given instructions that attempts should be made to contain the present outbreaks as far as possible, so as to leave the field clear for the committee to consider the problem objectively It might be that the committee would advise that the disease should be allowed to spread or that it should be introduced deliberately But if this decision were to be taken it would be better that it should be taken deliberately after considering all the evidence rather than be forced on us prematurely by leaving present outbreaks unchecked The committee had endorsed the action taken by the Minister, and the Ministry would be helped in dealing with this problem if farmers and landowners would coöperate by intensifying their efforts to destroy rabbits on their land Myxomatosis even if it spread would give no justification for relaxing our efforts to destroy rabbits by other means. He expected the committee to report before the spring because the disease was likely to spread more in the spring than in the winter when most of the insects were dead or not active.

Shortage of Mental Nurses

In the House of Commons on Nov 12 Mr R. J MELLISH who is a member of the South East Metropolitan Regional Hospital Board called attention to the shortage of nurses in mental hospitals, and especially in mental-deficiency institutions. The problem was of national importance, but its extent, he suggested was typified in his own region where the two mental colonies had 500 empty beds due to lack of staff As a result only low grade defectives, for whom little could be done but who had to have institutional care, could be admitted ; and even for these patients there was a waiting list of 472 urgent cases. By improvisation it had been possible only to admit 158 One regional hospital board had suggested that magistrates should be asked to stop making court orders for admission of these cases to an institution Doctors and nurses were anxious to have a share of the high grade defectives who responded to treatment —and when a hospital was over-weighted with low-grade patients, the nurses became frustrated

As remedies for this situation Mr Mellish urged that the wages and working conditions of mental-deficiency nurses should be improved considerably A national press campaign was needed to attract more people as part time or full time volunteers. There must be no further call up of student male nurses. The Minister must provide special staff accommodation and facilities for recreation particularly in mental colonies in remote areas

Miss PATRICIA HORNSBY-SMITH parliamentary secretary to the Ministry of Health agreed that the gravity of the problem called for national action The number of patients, she continued had risen from 47,010 in 1949 to 53 066 in 1952 At the same time as these patients had been absorbed the waiting lists had risen from 5316 to 0300 In the mental hospitals there were at the moment 137 039 patients resident and overcrowding, she was sorry to say was at the rate of 14 7% In the country as a whole 615 more beds had been opened and the Minister was insisting that the mental health service should have a fair share of the money available to the regional boards

The estimates for 1953–54 included schemes for 1314 new mental-deficiency beds and 007 mental hospital beds. In 1954–55 there would be a special allocation of £1 million the Mental Million which the Minister had insisted must go over the normal allocation of the boards, to the mental side. Through this programme they hoped to provide 1200 mental-deficiency beds and 800 mental hospital beds. In addition to these two programmes three large centrally financed schemes from other funds for mental-deficiency hospitals would provide 800 beds within three years Within the next five years, this plan should provide 3000 mental-deficiency beds and 1500 mental-hospital beds It would, however be some years before all the backlog could be absorbed

But the main problem over and above accommodation, she agreed, was the shortage of nurses Although the number of mental-deficiency nurses had increased from 3812 in 1948 to 7676 in 1952, it was still well below what we needed She would report to the Minister of Labour the suggestion that there should be no more call-up of nurses for National Service The Minister had decided that in the campaign for the recruitment of nurses the bulk of the money should be used essentially for publicity and recruitment for mental nurses In coöperation with the Ministry of Labour and National Service there was to be a programme of local campaigns to encourage people to help their own local colony The proposal of the Standing Mental Health Advisory Committee that nurses on the general register, after a shorter period of training, could be admitted to the mental nursing register, was under discussion with the General Nursing Council Several experimental schemes were under consideration or in operation whereby nurses might qualify for admission to both the mental and general parts of the nursing register in a reduced period They hoped by these means to induce some of the nurses on the general register to enrich their training and enter the mental side The main object was to make the mental-nursing training sufficient for the highest posts in mental nursing At the moment nurses needed the full double qualification before they could become matrons The Minister had appointed for the first time a male and a female mental-nursing officer to the Ministry staff Rates of pay were under consideration by the Nurses' and Midwives' Whitley Council, and it had been urged on them that the rates should be made more attractive But she believed we must also get a new outlook on the part of the public so that parents no longer deterred their children from taking up mental nursing by saying "Nursing, if you must, but general nursing and not mental nursing" People must realise that "there is as great and fine a vocation in nursing those who have sick minds as in nursing those who have sick bodies"

QUESTION TIME

Fog-masks

Replying to a question, Mr **Iain Macleod**, the Minister of Health, said that he was advised that in the present state of knowledge no mask which people could be expected to wear for long periods was likely to give complete protection, but that some types of mask might help those most likely to be affected by smoke polluted fog—namely, people suffering from existing disease of the heart or lungs. He was, therefore, proposing to enable doctors, if they felt it to be desirable, to prescribe under the National Health Service specified types of mask for patients suffering from these conditions who lived or worked in an area where smoke polluted fog was likely to occur The necessary regulation would become effective on Nov 17, and masks should normally be available under the N.H S

Condemned Meat

Mr **Barnett Janner** asked the Minister of Food whether he was aware of the anxiety felt by sanitary inspectors over the auctioning of meat condemned as unfit for human consumption, that such meat might be made available for human consumption in the way of manufactured food products, and whether, in the circumstances, he would re examine the present system relating to such sales —Major **Gwilym Lloyd George** replied I have given careful consideration to the representations which I have received on this matter and have decided to make certain changes in the present arrangements for the sale of condemned meat from Government slaughter houses

I should explain that it would be an offence under the Food and Drugs Act to offer condemned meat for human consumption and that responsibility for the enforcement of this provision rests with the local authorities in carrying out their statutory duties All condemned meat sold by the Ministry is stained green before it leaves the slaughterhouse and local authorities are notified of the names and addresses of the buyers Local authorities are given the right of access to Government slaughterhouses and it is being made clear to them that notwithstanding Crown right their inspectors may take any meat unfit for human consumption and dispose of it as they think fit I am also revising the present conditions of sale of condemned meat from Government slaughterhouses by requiring that before condemned meat is sold retail it should be sterilised

Dr **Barnett Stross** Could the Minister tell us what the process of sterilisation is that is contemplated?—Major **Lloyd George** Boiling for an hour

Myxomatosis

Major W J **Anstruther Gray** asked the Secretary of State for Scotland how far the disease of myxomatosis had been reported among rabbits in Scotland.—Mr **James Stuart** replied I have received no reports of outbreaks of the disease in Scotland, but the North of Scotland College of Agriculture are conducting experiments with the virus on a few small islands

Mr **Somerville Hastings** Is the Minister convinced that this disease can be confined to an island and will not spread to the mainland?—Mr **Stuart** That is the advice which I have received I think that that is the case I hope so

Nerve Gases

Replying to a question, Mr **Duncan Sandys**, the Minister of Supply, said that no complete antidote had yet been discovered to nerve gases A partial antidote had been found, but it was not regarded as wholly satisfactory

Accommodation for Mental Defectives

Replying to a question, Mr **Macleod**, Minister of Health, said that the numbers of mentally defective patients on local health authority waiting lists on Jan. 1 last for England and Wales were 3527 urgent and 5461 non urgent

Territorial Doctors' Car Allowances

Replying to a question, Mr **Antony Head**, Secretary of State for War, said that he had already had evidence that some of the present rates of allowance for use of their own cars on Army business by doctors doing Territorial Army service were causing dissatisfaction, and he was giving consideration to that problem

Caponised Cockerels

Lieut Colonel W H. **Bromley Davenport** asked the Minister of Agriculture what advice he had received from his scientific advisers on present-day methods of caponising cockerels, what severe biological changes resulted in birds so treated, and what steps had been taken to ascertain what were the consequences of the heads, necks, and offal of such birds being consumed in large quantities by pigs—Mr G R H **Nugent** replied The Ministry is advised that the chemical caponisation of cockerels by means of synthetic female sex hormones is a satisfactory method of producing good quality table poultry The effect of the treatment is to arrest the development of the male characteristics of the bird It is recommended that the treatment should be discontinued a fortnight before slaughter, and that waste products and offals of birds that have been subjected to this treatment should not be fed to any class of livestock including pigs. This advice is based on an assessment by our scientific advisers of the results of investigations in the United States. There have been, so far as I know, no such investigations in this country

Lieut Colonel **Bromley Davenport** asked the Minister of Food what evidence his scientific advisers had to show that the consumption of caponised cockerels had an adverse effect on the consumer —Major **Lloyd George** None, Sir

Junior Hospital Medical Staff Appointments

Mr **Roy Mason** asked the Minister of Health what action had already been taken in reply to recommendations made to him by the chairmen of the hospital management committees of the Sheffield Regional Board, what other points were under consideration, and what action was contemplated. —Mr **Macleod** replied Two of the recommendations on junior hospital medical staff came from the chairmen of the board's hospital management committees, one on scales of remuneration and one suggesting the employment of experienced medical officers to supervise work in casualty departments The question of remuneration is before the appropriate Whitley Council as regards the second point, I have indicated to hospital boards that I am prepared to approve the appointment of casualty officers of senior standing in appropriate circumstances I am discussing with the profession other aspects of the shortage of junior hospital medical staff but I am not yet ready to make a statement

Proprietary Medicines

Dr STROSS asked the Minister how many medical preparations listed in the *National Formulary* were dearer than the proprietary brands of the same preparations —Mr MACLEOD replied: Of preparations in common use in general practice the cost to the Health Service of the following 18 is greater than that of their proprietary equivalents 10 others may be dearer according to which of the equivalent products is prescribed or the size of the pack from which it is dispensed

Tab mepyramin. maleat *N F* 100 mg
Tab succinylsulphathiazol. *B.P*
Tab pethidin. hydrochlor *B P* 50 mg

Cost of N H.S Prescriptions

In answer to a question Miss PATRICIA HORNSBY-SMITH gave the following figures for the number and cost of prescriptions in the National Health Service in England and Wales for September, 1953

Number (declared by chemists)	16 524 000
Estimated prescriptions per form	1 72
Estimated cost per prescription	47 80*d.*

Charges for Surgical Appliances

Mr GEORGE THOMAS asked the Minister how much he had saved by the imposition of a charge on surgical shoes rupture belts, and elastic stockings. Mr MACLEOD replied I estimate roughly that since the introduction of the charges the annual cost to the hospital service of these articles has been reduced by about £400 000 I am looking into the position of elastic hosiery supplied on the prescription of general practitioners.

Cost of the Social Services

Replying to Dr STROSS Mr J A. BOYD CARPENTER, financial secretary to the Treasury said that the cost of the social services in terms of a percentage of the national income for 1938–39 was 12% and for 1952–53 17%

Prostitution and Male Importuning

Replying to a question, Sir DAVID MAXWELL FYFE said that he had for some time been concerned about the problems of prostitution and of importuning by male persons in London, though he thought it important to view this matter in a proper perspective and not to draw exaggerated pictures of the extent of the evil to be found in the streets He had, therefore been anxious to obtain advice and information from various quarters, including information about the law and practice in other countries, which might help in considering whether any amendment of the law, or any changes in the present methods of enforcing the law would be likely to help in dealing with the problem, As part of these inquiries, he had arranged for an assistant under secretary of State in the Home Office and a commander of the Metropolitan Police to visit the United States He had recently had a discussion with some of the Metropolitan magistrates who dealt with cases of this kind arising in the West End with a view to getting first hand knowledge of their impressions and experience He did not of course seek to advise the magistrates how they should deal with particular cases coming before them He was studying various aspects of these problems but he had no further statement to make at present

Fees for Cremation Certificates

Replying to a question Sir DAVID MAXWELL FYFE said that the British Medical Association had advised doctors that a suitable fee for the completion of either certificate B or certificate C for cremation was two guineas plus a mileage allowance where applicable at the rate of 1*s* per mile, or part of a mile, each way outside a radius of two miles. In view of this action he did *not propose* at present to make use of the power contained in the Cremation Act 1952 to prescribe maximum fees.

In England Now

A Running Commentary by Peripatetic Correspondents

'WHY must your weekly medical journals be so dull ? '

I looked up from my scrutiny of one of the journals to see my wife idly turning over the pages of the other one

I don t think they are so dull, dear

Well I suppose that it s all right for you But considering that every medical household in the country probably takes at least one of them if not both I think they might cater for the family a little more

But they are not really supposed to be for the family

Well, they should be.'

After that piece of unassailable feminine logic the discussion could proceed no further but I began to wonder if there wasn't something in what she said There is the *Family Doctor* of course, but that is hardly the same thing Something more like the *Doctor's Family* would be needed

There would have to be a Woman Doctor s Page with fashion notes on natty two piece dark blue suits, hints on how to get help when the car breaks down, and easy recipes 'for your husband to make " The school-children could have their growing minds trained along the right lines by a comic strip: *The Adventures of Lionel Scalpel—Medical Student* sounds exciting Lionel would get himself involved in all sorts of thrilling incidents—trapping the porter who is stealing the precious supplies of cortisone discovering that the mysterious patient in Surgical 2 is a Russian spy who is after the Senior Surgeon a prominent Territorial officer and so on

An advice column, run by an understanding sympathetic, but sensible Auntie would have plenty of material A young house-surgeon is in love with the new theatre sister and is jealous of the surgical registrar who seems to be paying her a lot of attention; what should he do ?

Even the Original Articles could be brightened The longer ones could be serialised, breaking off each week at the beginning of an exciting development, with a little note in the approved manner at the end of each part—'Will methylphenylpolysyllabalate reduce the blood pressure ? Is it toxic ? How many patients were treated ? Don't miss next week s thrilling instalment !

* * *

A harassed steward last week notified our pathological department that the dietitian had received an order for 8 fertile eggs a day for a patient. If eggs were sent from the kitchen, could the pathological department please fertilise them ? At the time the pathologist was reading an article by Dame Harriette Chick, but felt that not even this eminent authority on nutrition would be able to help A colleague suggested that Sir John Cockcroft might be approached We wonder why the request came to us: of course we have a Henman on the staff

* * *

A consultation in Bermuda is something to dream about. It is also one of the few experiences that make an exception to that great law to travel hopefully is better than to arrive ' Arrival at 3 A.M. in a tropical night meant being greeted by a continuous chorus of singing (sic) tree frogs and a pleasant journey across the island in a 10 H P car (the largest allowed) at a speed which kept strictly to the universal limit of 20 M P H Speed traps are plentiful and radar-controlled and there is no argument.

A swim in the sea at 70 F was followed by a sleep—and then an awakening to a vision of deep blue sea and sky scarlet and green trees, pink beaches, and honey coloured rocks That day I met my American colleague. Well now my name s Bill we've got a little party this evening for you so s you can get the atmosphere before talking shop

At the consultation I was for once at a much needed advantage Complicated laboratory tests or unusual investigations were impossible, and my American friend felt that a complete diagnosis that had not gone fully into all possibilities was uncertain; for he tended to trust investigation more than experience Similarly he considered management almost impossible on general principles of medicine alone, without "getting under your patient's hide" by living with him for at least 48 hours *Just as certain English humour is difficult for Americans by reason of its understatement, its mental short-cuts, and its reliance on implication, so it seems difficult for them to understand how, for example, a firm diagnosis of disseminated sclerosis can be reached without even a lumbar puncture* But our discussions taught me that this type of American medicine is painstaking, thorough, and comprehensive, and that a strong thread of common sense runs through it

I left this beautiful island with regret, and I wish I had seen it before cars were allowed there and before those beautiful red cedars were destroyed by a scab imported on a rare plant brought in by an American millionaire Re-afforestation, I was told, will take ten to twenty years As the plane circled the island I thought of the haunting calypso rhythms, the brightly coloured trees, the taxi-driver who stopped just to pick me a night-blooming cereus flower, the solemn-faced, clean, gaily dressed coloured children with their English accents and their passion for cricket, and above all the lovely warm bathes in the early morning

Ah, well, it all seems like a dream I must go and do a domiciliary

* * *

The other day a young woman of our acquaintance saw her five-year-old son off to school for the first time This is a time fraught with emotion for any mother, and she felt as sad as most as she returned indoors to wait for midday and his safe return Would they be kind to him? Would he be good? Would he be miserable? At noon home he came, hair smooth, knees ungrubbied, and to all outward appearances unchanged Our friend heaved a sigh of relief and was about to get on with the lunch, when a hand caught her skirt and a small trusting voice demanded, "Mummy, where did I come from?" Changes with a vengeance! However, she is a sensible girl, so she sat down and explained the facts of life with simplicity, ease, and a commendable lack of self-consciousness Towards the end of her story she noticed a slight wriggling and slackening attention, so she stopped to ask what had prompted the question "Well, I just wondered as we hadn't been here always and the boy who sat next to me came from Guildford"

* * *

The obstetricians are understandable with their D.M.P., E.U.A., Z.A., D.E.D., and B.B.A.'s The X-ray man's N.B.I. makes sense too, but B.A.P.W.O. & P.P.D. which is the E.N.T. H.S.'s only report on *my Jimmy Jones is* N.B.G. to the poor G.P. and G.O.K. what it all means

  he gives a despairing yell
The electrolyte shines extremely bright
  but it's now a padded cell

Letters to the Editor

THE INSULIN MYTH

SIR,—Dr Bourne (Nov 7) has done well in destroyi the myth of the cure of schizophrenia by insulin Havi treated schizophrenics for many years by various method I have now no doubt that those who recovered aft being treated by insulin recovered in spite of the trea ment and not because of it, and I am relieved th I no longer submit my patients to a treatment so unplea ant, dangerous, and useless Diagnostic and prognost problems so perplex those who deal with this disea that figures of recovery rates are apt to become expre sions of personal bias, and, for my part, I am convinc that most acute young schizophrenics recover natural from their first attack and many from a second, recover which usually occurs within a few months, may ta place after times varying from a few days to seve years Any treatment given to these patients is like to be hailed as specific by the over enthusiastic. As t treatment of schizophrenia by insulin does not increa the rate of recovery, shorten the duration, or preve recurrences the method should now be consigned to t dustbin of therapeutic failures The patients will th have less unpleasant memories of their time in hospital.

For chronic schizophrenics electroconvulsion thera may assist in relieving them of some of their sympto and in making their lives less turbulent, but bett results can be got where patients are well nursed b an adequate staff under pleasant conditions, and whe this is done E.C.T. is unnecessary

J GIBSON

Gloucester

SIR,—May I join issue with Dr Bourne in defence a treatment whose relegation to the realms of psychiatr mythology is surely premature?

I think it is unfair to judge the value of any treatme applied to chronic cases, so I would disagree that t effects of insulin in chronic schizophrenics could ever b used as a basis for estimating its efficacy Analogousl one would hesitate to assess penicillin by its effect chronic infections in which tissue changes had alread occurred In chronic schizophrenia, morbid reactio patterns are already established and are notoriousl difficult to influence in a lasting way by any treatment.

Turning to early cases, Dr Bourne has rightly empha sised the peculiar difficulties of assessing the results any treatment in a condition like schizophrenia. Th virtual impossibility of obtaining adequately matche control groups is not surprising in a syndrome (on hesitates to say disease) so protean in its manifestatio Within these limitations, however, numerous invest gators have reported better results with insulin than wi routine hospital care or E.C.T. in large groups of subjec Because of the lack at present of objective diagno criteria, their results are always open to arguments suc as Dr Bourne has advanced

One might, I think, compare the present state treatment in psychiatry with that in medicine a centur ago Our relative ignorance of ætiological factors or th natural history of the disease in many cases of schiz phrenia forces us into an attitude of empiricism Insuli treatment is one of the most powerful methods at ou disposal for altering both the internal environment an the relationship between the patient and his helpers. I we cannot be quite certain that insulin does not preve patients from subsiding into "this most stagnant conditions," we should give the patients the benefit the doubt

Cane Hill Hospital,
Coulsdon Surrey

F B. CHARATAN

SIR,—The paper by Dr Bourne indicates that co troversy still persists, twenty years after Sakel's origina discovery, over the value of the deep insulin treatment schizophrenia Dr Bourne appears to me to base his arguments against the efficacy of insulin on three points first, that there is no proof that a similar number of untreated cases would not get well spontaneously second, that E C T is as good or better than insulin and third, that the character of mental disorder may be changing in favour of a more benign type of schizophrenia

Commenting on these points in their reverse order there is as far as I know no statistical evidence that the severe forms of schizophrenia are diminishing in numbers What we may be seeing is a larger number of schizophrenic breakdowns in which environmental causes and emotional stress play a larger part than hitherto With regard to the second point, one would have thought that there is by now adequate evidence that the results of insulin are better than those of E.C T in schizophrenia the work of Linford Rees may be selected as an illustration. Furthermore one believes that at most hospitals E C T is given before insulin in the treatment of schizophrenia, the reasons for this being that insulin treatment is more prolonged and also more dangerous

Dr Bourne s first point is the one on which any attempt to evaluate insulin treatment must turn He points out that there are indeed many variable and unknown factors in assessing the results of any treatment and until there is conclusive proof that the chronic schizophrenic population of mental hospitals is diminishing in relation to the total population of the country we cannot be certain that the physical treatments are really effective in the long term management of the psychoses Although I have no figures to hand I am certain that insulin not only shortens the average period of stay in hospital but that it also prevents relapse and lowers the readmission rate. The following summary of the figures at this hospital since an insulin unit was opened for the first time early in 1952 may be of interest

Fifty-six patients have so far been treated All were suffering from schizophrenia Two patients did not complete the course and one died. The remaining fifty three all had at least 40 comas, except for one patient who recovered and has kept well after 20 comas. Forty three of these patients are out of hospital and are known to be holding their own although in nine cases the ultimate outcome is thought to be doubtful and some of these are not working

Of the ten failures, two have subsequently been readmitted to other hospitals, two have recently been readmitted here and the remaining six have stayed in the hospital since treatment was completed Of the forty three patients discharged, one had a leucotomy after insulin had failed and her recovery may be attributed more to this than to the insulin Therefore, out of fifty three patients, thirty three or about [illegible]% may be said to have recovered after a course of insulin treatment. In eighteen of these cases insulin was successfully given after a course or courses of E C T had failed. We thought that about twenty-seven of the patients were suffering from dementia præcox and would not have recovered without treatment, while in a further eight cases recovery was regarded as doubtful unless insulin had been given. Thus a so-called spontaneous-recovery rate of between 35% and 50% only could have been expected from this group and then the period of stay in hospital would undoubtedly have been much longer Those who congratulate themselves on the fact that the schizophrenic patient has recovered spontaneously probably do not consider the extent to which schizophrenic morbidity exists These patients, although at home and working lead restricted, poorly adapted lives, often continuing to indulge in psychotic fantasies.

Most of us who are experienced in insulin treatment would agree that the quality of the insulin remissions is much better In 1947 I reported[1] on 303 schizophrenic patients treated with insulin. 60% of the 61 patients that had been followed up for more than five years were still out of hospital—a figure which compares favourably with the present recent series.

We must further ask ourselves whether about 40% of schizophrenics would remit spontaneously if kept at home, supposing this were possible on social grounds. Is it indeed true that ‘ few mental hospitals, even today are able to offer recently admitted patients much more than custodianship rug making the cinema, and a chat every week or two with the doctor ’ as Dr Bourne asserts? The serious shortage of medical staff in most mental hospitals may limit psychotherapy but a grave injustice is surely done to the part which the nursing staff and the general discipline and atmosphere of the hospital can play in helping the patient particularly where the patients in the hospital are organised on a group basis. Furthermore most progressive mental hospitals can now offer a range of treatments which is impressive compared with even twenty years ago

There is great need for some criteria concerning the depth and duration of coma in insulin treatment. Psychological studies show that nearness to death is an important factor in recovery from schizophrenia. It is of the greatest importance that insulin treatment should be adequately carried out, with each coma carefully supervised to allow the patient to become as deep as possible without serious danger to life We might also do well to avoid thinking in terms of ‘ physical as opposed to psychotherapeutic, treatments If psychotherapy assists in the recovery of our insulin patients let us use it even if it upsets the figures of the statisticians

Dr Bourne rightly asserts that the recovery rate in early schizophrenia is higher than after the disease has become established. It seems to me that the only way we shall persuade early schizophrenics and their relatives that hospital treatment is necessary is by offering them some definite form of treatment. One would welcome any new approach either on an outpatient or inpatient basis, which would help to deal with this grave problem To attempt to dissolve a treatment which is widely accepted as the best weapon we have into a myth appears to me a retrograde step

In view of the confusion which still exists regarding insulin treatment, I would like to suggest the formation of a small professional committee possibly under the ægis of the Royal Medico Psychological Association, to inquire into the present state of insulin treatment in mental hospitals and the results that are being obtained

THE LETHAL AEROSOL

SIR —Your articles on fog have been most instructive and if taken in conjunction with the demands of the Local Medical Committee for the County of London should lead to decisive action

There seems little doubt, as you suggest that the sulphur laden aerosol in cold weather is responsible for much respiratory damage. I would like to describe what I think is a perfect mechanism for making such an aerosol I live 300 yards upwind from a large power station As dawn breaks one can watch a billowing cloud of cooling steam float from the cooling towers This often extends across the sky for two or three miles into it the power station chimney belches huge quantities of unwashed smoke and grit. Under favourable weather conditions this goes on for hours the sun is blotted out and a drab half light replaces its rays On other days we are not so fortunate for the water vapour descends on the main road and brings traffic almost to a standstill

There is an increasing number of power stations in Greater London. Within a radius of one mile, Fulham, Lotts Road and Battersea consume 2 000 000 tons of coal a year Can we wonder that Westminster and County Hall were the centre of last year s lethal smog? Can Westminster Abbey be saved while being subjected to such continuing sulphur baths?

The remedies, Sir seem fairly simple. May we hope that too many committees do not obscure the issue and delay action

London, N W 10　　HORACE JOULES

VAGARIES OF INTELLIGENCE

SIR,—We note that Sir Cyril Burt, in his letter of Nov 7, does not disagree with the main general conclusion of our article He confines himself to removing "one or two *misconceptions,*" some of which seem (if we may say so) to be of his own creation

He states that the criticisms we made of the I Q are by no means new, and asks who has ever disputed I Q variability Surely he must be aware that there is a widespread belief, both in uninformed and informed circles, that the I Q, as currently used, is virtually constant, and this belief is supported by many reputable textbooks

He makes the important statement that the formula for calculating the I Q, suggested by himself and others, is based on a fallacy—i e, that the changes in mean mental age and in the standard deviation are rectilinear, whereas in fact they are curvilinear He then goes on to say that this formula is the main cause of I Q inconstancy, but that it can largely be corrected by "adopting a more complex formula" He does not mention such findings as those of the Harvard Growth Study, the results of which are not expressed in terms of the usual I Q formula, but as observed means and observed distributions Does he seriously suggest that the changes in intellectual status demonstrated by Dearborn and Rothney, or even in our own small experiment, are mainly statistical artefacts ? In the latter study it was quite clear that those who had made the larger I Q increments could deal more effectively with reality, as sampled by their greater success in solving objective and standardised test problems In addition, of course, the Wechsler test overcomes the difficulties implicit in the use of the conventional I Q formula, as is indicated in Dr Wechsler's book on the subject

Sir Cyril says that we criticise previous views, including his own, and he quotes us as saying "These investigators . . . rarely, if ever, submit their hypotheses to experimental proof" He has omitted the key phrase of the sentence, which reads "These investigators, *however, while offering hypothetical explanations for the changes in intellectual level which they demonstrate,* rarely, if ever, submit their hypotheses to experimental proof" He thus implies that we criticised himself and others for not proving I Q inconstancy, on the contrary, we quoted his experiment as supporting our thesis Our only criticism, as the full quotation clearly indicates, is that the investigators, having demonstrated the fact of I Q variability, failed to take their work a stage further by verifying the often important hypotheses which they advanced to explain it (For example, "some happy change in home conditions seemed responsible" for some I Q increments, was one of Sir Cyril's own hypotheses)

Sir Cyril observes that one reason for I Q inconstancy is that so many who employ intelligence tests "have never been trained in their administration and interpretation" This is undoubtedly (and very unfortunately) a feature of some administrative and clinical practice, our article, however, confined discussion to researches carried out by well-established psychologists He also points out that no trained psychologist "relies on tests alone—much less on a single test—in any doubtful case" Unfortunately, however, decisions about an individual's future are sometimes made (whether the psychologist likes it or not) by the authorities concerned, on the basis of a single test score, which may have been assessed by someone with the lack of training which Sir Cyril properly deplores, and under conditions which may be by no means ideal

In brief, it is not infrequently observed that bright children may in time show less promise than had been hoped, or that dull children may sometimes blossom to a level which surprises those who knew them Individuals are not static, but capable of change, within limits which are as yet imperfectly understood. We are sure that Sir Cyril will agree that we need to identify the factors which influence such changes, in order t play a more positive rôle than that of passive spectators who merely record them as and when they occur

A. M CLARKE.

MOLLUSCUM PSEUDOCARCINOMATOSUM

SIR,—In your leading article of Oct 17, you state tha confirmation of the occurrence of this condition in othe countries would be welcome

I am indebted to a dermatological colleague, Dr A D Muir, for calling my attention to the condition abou two years ago, and I was able to show 5 examples at th meeting, in May, 1952, of the Pathological Society New Zealand During the past fourteen months I hav made 27 such diagnoses, and I have raised the possibilit a further 17 times (The histological differentiation fro squamous cell carcinoma of the lowest grade of malignancy or from some hyperkeratoses is not always possib on tiny biopsy fragments) Without knowledge of th condition I would have (and in the past had, in fact diagnosed many of these as squamous cell carcinomata about a 100 examples of which were seen in these fourtee months The follow-up records of the local cancer clini confirm a number of such misdiagnoses

These rough figures support both the quoted frequenc of the condition and your concluding remark tha "statistics of incidence and prognosis of skin cancer wi need to be drastically revised"

Public Hospital,
Christchurch, New Zealand

D T STEWART
Director of patholog

TEETHING

SIR,—I read with interest the remarks of one of you peripatetic correspondents (Nov 7) on the placeb I could quote one or two cases from experience tha would require him to deal with "teething" under th heading of the placebo in its ecclesiastical and not m medical sense

Quite a lot has been known for some time about th histological, anatomical, and morphological details o normal eruption of teeth In the natural history o eruption,[1] there is one point at which trouble may an often does arise, and it is easy to understand why A the tooth approaches the surface in the mouth the cr epithelium fuses with the enamel epithelium of th tooth, immediately before the crown of the tooth emerges, this combined epithelium breaks down in th centre and is absorbed—and thus the tooth is exposed For some time before actual eruption there is therefore a thin layer of soft tissue between the crown of a har tooth and any hard object the child may bite upon

In the case of the first and second deciduous molars which are square and flattish teeth and which normally erupt at about one and two years respectively—when th child should be biting hard objects and trying out i dental apparatus—there is usually irritation of th overlying epithelium and sometimes they actually mast cate this piece of themselves Local inflammation i common and a vicious circle may arise

Instinctively the child seems to bite upon the irritation t relieve it, with anything it can lay its hands on or get i jaws near While actually applied, pressure does seem t give relief But it also increases the inflammation and wh was bad becomes worse The crying increases and the bab gets tired—and tired, cries the more Soon it becom exhausted and another vicious circle begins It is not th local condition that is usually serious (though it can be) b the fatigue that this trivial matter causes—and worse, th bad habits that may have their origin in the fuss that acco panies the bad tempers of a tired and crying baby and tired and anxious brace of parents, especially if it is the

---

1 Toller, J R *Brit dent J* 1948 84, 255 *Ibid,* 1948 85, 1

first baby. Unfortunately the doctor can rarely be sure that the trouble is only a tooth coming through and his uncertainty is communicated to the parents, who are anxiously appraising every sniff the child makes. The parents expect their doctor to be omniscient and cannot appreciate (anyway on these occasions) that clinical pædiatrics and veterinary science have much common ground. The sedatives that the wise physician orders for all concerned—baby, parents, and himself—if he has been called out in the early hours, are the best and only possible treatment.

Your correspondent, I feel, may go on using 'teething' as a diagnosis. Very often it will be the right one. Until I had babies of my own I dismissed 'teething' as an old wives' tale.

And one must always bear in mind accidents of eruption. A cyst of eruption may break down and become infected. These cysts are more frequent than is commonly realised. I have seen severe cases of Vincent's angina focused around an erupting first permanent molar in the mandible. The troubles of erupting third molars—or of third molars that cannot erupt—are well known.

Cambridge. J. R. TOLLER.

RECURRENT PAROTITIS

SIR,—It is highly probable that, contrary to the impression given in your annotation of Sept. 26, only a few cases of recurrent parotitis of childhood are caused primarily by bacterial infection. Mention should be made of another condition called periodic sialorrhœa. This is a curious disorder of unknown origin in which the salivary glands swell at regular or irregular short intervals over many years. The swelling is accompanied either by xerostomia or sialorrhœa. We have described[1] a case and referred to others that have been reported.

While it is possible that secondary infection with pneumococci or staphylococci may occur in such cases and require treatment, much unnecessary surgical treatment for the removal of supposed foci of infection and unnecessary and possibly harmful massage and antibiotic therapy could be avoided if correct diagnosis were made.

American University of Beirut,
Lebanon.

HOBART A. REIMANN
Professor of Medicine.

ALL IN THE DAY'S WORK

SIR,—It seems, from his Widdicombe letter last week, that Dr "Bill Brewer" is going to do side-room tests not only for his own patients but for those of his partners. Will he not get bored with this? Most practitioners find a certain satisfaction in themselves completing the examination of their patients, including these simple tests; and thereby they get a better grip of the case. Where the responsibility is divided the partners will have to exchange written notes requesting and reporting on a test; which wastes time. The patient's time may also be wasted: supposing that the hæmoglobin is to be estimated with the M.R.C. grey wedge hæmoglobinometer, the patient will attend one doctor, be referred to Dr Brewer for the test, and then have to come back the next day for the result. Why not use a Sahli hæmoglobinometer? Then the test can be completed by the patient's own doctor in a few minutes. This method is quite accurate enough.

Is not Dr Brewer a little audacious in proposing to diagnose pernicious anæmia from the appearances of a film alone? After all, on his findings may depend whether the patient attends for injections monthly over the next twenty years. It seems a pity, too, that he is not going to do white-cell counts. These help greatly before starting to treat pneumonia or pleurisy, and also sometimes in acute abdominal disorders; and occasionally they bring to light a case of acute leukæmia.

G.P.

THE R.M.B.F.

SIR,—I venture to remind your readers of Lord Webb-Johnson's Christmas gifts appeal published in your issue of Oct. 3.

The distribution of gifts is made well in advance of Christmas Day and I earnestly hope that those who have not yet responded to the appeal will send their contributions as soon as possible to the Secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, marked "Christmas Gifts."

FRANK JULER
Honorary Treasurer.

DIARRHŒA AFTER GASTRECTOMY

SIR,—Mr Williams and Mr Pullan (Nov. 14) sometimes found it necessary to give their patients suffering from necrotising enteritis 9 g. of sodium chloride and 3 litres of water in an hour. To do this, they infused 1 litre of physiological saline solution and 2 litres of 5% dextrose solution. In your leading article on the subject you state that treatment consists in "the infusion of glucose-saline solution in large quantities—sometimes as much as three litres an hour." This is three times as much sodium chloride as Williams and Pullan were using, whether it be measured in grammes or in milli-equivalents.

A dehydrated patient requires either water or salt and water, and 5% dextrose solution and/or physiological saline are used to make good the deficiency. The amount to be given and the solution to be used depend on the needs of the individual patient. If these are in doubt, the writings of Marriott should be consulted. Dextrose-saline is not a compromise: it is a hypertonic solution containing 0·9 g. of sodium chloride and 5 g. of dextrose in each 100 ml. and it will quite soon produce thrombosis of the vein, and œdema in a patient who is not deficient of salt.

Mr Richardson, Dr Billinghurst, and Dr Vere (Sept. 19) treated a patient who had an adynamic ileus. After five days, during which time the patient "received water only by mouth and 5% dextrose intravenously," there was sacral œdema and the serum-sodium level was 148 m.eq. per litre. 3897 ml. of fluid was aspirated from the stomach and 8790 ml. of urine was passed. The ileus was still present on the fifth day; there would, therefore, be a considerable amount of fluid containing sodium in the small intestine. Some salt, also, must have been lost in the sweat during those five days. Yet on the fifth day this patient had too much sodium. I feel sure that the patient during those five days was being given either saline or dextrose-saline.

May I suggest that dextrose-saline solutions should be discarded—except for a few bottles which might be kept for diabetic patients. I have mentioned the effect of this solution on the veins. It also causes inaccuracies in the literature, and confusion among the medical and nursing staff who do not always appreciate the difference between dextrose-saline and dextrose solutions.

Victoria Infirmary,
Glasgow.

JOHN C. GRANT.

ISCHÆMIC NECROSIS OF THE STOMACH

SIR,—I was interested in reading the paper by Mr Rutter last week to note that he could find no published record of this complication during the past twenty years.

About two years ago I performed a post-mortem examination on a patient who died after a subtotal gastrectomy for gastric ulcer. His condition before death suggested strongly that a suture line had parted, but death was in fact due to the condition Mr Rutter describes. The suture lines were intact but the stomach remnant, which was almost entirely necrotic, had a large rent, and tore further on the most gentle handling Neither the surgeon, who was present, nor myself had any doubt but that an excessive number of vessels had been ligated in mobilising the stomach in the course of a difficult operation for a high lesser curve ulcer, and that this had precipitated the condition

---

[1] Reimann, H. A., Lindquist, J. N. *J. Amer. med. Ass.* 1952, 149, 1465.

At the time I assumed, wrongly it would seem, that this must be a well-recognised complication, and thought no more about it until I read Mr Rutter's paper In view of his remarks, I feel that you might be interested in hearing of a similar case

United Liverpool Hospitals ROBERT P TOWERS

TUBERCULOSIS

SIR,—In your issue of Nov 7 Professor Francis says that I have tried to show "that as one eradicates tuberculosis from cattle the death-rate from pulmonary tuberculosis increases" This is only partly true my whole theme about the inverse relationship between human and bovine tuberculosis is based on the increase in the *incidence* of the disease in countries and counties with a high proportion of tuberculosis-free cattle I have published [1] figures in your columns which support this view These figures showed a very much greater reduction in human notifications in those Scottish counties with few tuberculin-tested cattle, and this applied to both pulmonary and non-pulmonary disease I have also collected figures from the English counties, and these suggest a similar connection

In my opinion, the recent small increase in notifications of human tuberculosis in England is entirely due to the attested cattle scheme My conclusion is that the consumption of milk designated "Tuberculin-Tested" is not only failing to prevent human tuberculosis in England but is very substantially increasing it

HYALINE MEMBRANE IN THE NEONATAL LUNG

SIR,—From observations made on the microscopical appearances of the lungs in some 600 necropsies on stillbirths and neonatal deaths, I would agree with Dr Claireaux's conclusion, in his interesting paper of Oct 10, that the primary factor in the production of this lesion is aspiration of liquor amnii, and not, as suggested by Dr Emery (Oct 24), a local vascular change in the intrapulmonary circulation But, if hyalinisation of the inhaled squamous cells is a preliminary stage in the formation of the acidophil membrane in the infant's air passages, and if such hyalinisation can be produced experimentally, merely by incubation in normal saline at 37°C, it is difficult to understand why Dr Claireaux states that "*after aspiration*, the squames deposited in the lung undergo progressive hyalinisation" (my italics), for it seems that hyalinisation could occur equally well while these cells were floating in the liquor amnii, also at 37°C, before this is aspirated, unless some other factor promoting hyalinisation is postulated—a factor that operated only after the cells had found their way into the fœtal lung

If, indeed, hyalinisation can occur before the squames are aspirated, it is hard to understand why Dr Claireaux's rat no 7, which received an intratracheal injection of centrifuged deposit from liquor amnii which had not been incubated after collection, failed to show the formation of a true hyaline membrane On the other hand, if Dr Claireaux is right in saying that hyalinisation of squames occurs only after aspiration of the liquor amnii by the fœtus, it is surprising that a widespread, homogeneous membrane can be found in infants dying within only 24 hours of delivery, even though, as Dr Claireaux states, it is likely that many of these exhibit intra-uterine respiration only just before delivery—as in those infants that take a gulp of liquor amnii at delivery by cæsarean section In view of this it would be interesting to know why Dr Claireaux found it necessary to incubate the specimens of centrifuged liquor amnii for as long as 8 days before injection, and whether a true hyaline membrane, as in rats nos. 1, 2, 3, 5, and 6, could be produced experimentally after a much shorter period of incubation

With regard to the staining properties of the membrane, I agree with Dr Claireaux that "often, but not always, neutral fat can be detected" But I have found that sometimes very prolonged staining, often overnight, will reveal a sudanophilic reaction in hyaline membranes which would not appear with normal methods of staining. It is possible, therefore, that vernix is a more frequent, and perhaps more important, component of hyaline membrane than is suggested by Dr Claireaux.

GASTRIC RESECTION

SIR,—Mr Shepherd (Oct 24), in commenting on my article (Oct 10), emphasises the necessity for examination, while the operation is in progress, of the portion of stomach removed and if necessary of the remaining gastric segment Since my article was accepted for publication I have had a case which forcibly, and fatally emphasised this point

A man, aged 53, who was bleeding furiously and was in very poor condition, was subjected to laparotomy No lesion was detected and partial gastrectomy was done There was no ulcer to be seen when the specimen was examined. Bleeding recurred on the following day, and despite further transfusion the patient died some forty eight hours later The pathologist reported finding, post mortem, an acute ulcer less than five millimeters across and situated one inch below the œsophago-gastric junction, the open mouth of a vessel projected from this ulcer

As no fresh blood welled forth during the fashioning of the anastomosis, and none was aspirated from the intragastric tube, it can be assumed that, at the time of operation, the bleeding had temporarily ceased. Despite this it is possible that the lesion might have been detected had the gastric remnant been scrutinised, though I remain unconvinced that so small an ulcer, not actively bleeding, would have been found on gastrotomy, having regard to the much greater area to be examined.

Partial gastrectomy is advised by Mr Shepherd in all cases for which laparotomy has been considered necessary. I think that there are rare exceptions, such as case I in my article, it is in such cases that I regard gastrotomy as of potential value in that disclosure of the lesion as an acute ulcer or an acute erosive gastritis should influence one to spare the stomach Gastroscopy, excluded from the scope of my article, may be of help in these cases, since a finding, as above, would, in my opinion, exclude operation Dr Avery Jones's findings (Nov 7) support this view

Mr Moloney (Oct 24) takes me to task for a "burst of activity" in that I advocate gastric resection rather than gastrotomy when no obvious ulcer is found He goes on to describe his own technique, which involves an incision four to six inches long in the stomach wall, followed by division of the pylorus and opening of the first part of the duodenum, if his investigations are still negative a sigmoidoscope is introduced into the duodenum and sometimes even into the jejunum via a jejunotomy Following this "burst of activity," if Mr Moloney will allow me to borrow his phrase, he concludes that "if no ulcer is found after such methods, and an œsophageal source of bleeding has been excluded, it is fair to do a partial gastrectomy on an empirical basis" This appears to get us back where we started—though considerably later—and it seems to me that had Mr Moloney real faith in his method he would, when it yielded negative results, confidently close the abdomen leaving the exonerated stomach and duodenum to rest in peace.

---

[1] Pitcher L *Lancet* 1952, ii 1132

Surgery has an important part to play in the management of hæmatemesis, and in the difficult circumstances of the negative exploration one cannot afford to neglect any suggestion which may be of value to the patient I would be interested to learn more of Mr Lundsgaard Hansen's experience (Nov 7) with Rovsing s manœuvre One must not lose sight of the fact that the operation is done as an emergency measure to control bleeding and I believe that, with careful selection of cases when no obvious lesion is found gastric resection offers the patient a better chance of recovery if performed before rather than after, a series of gastrotomies, duodenotomies, and jejunotomies; consequently I think that when next I operate for hæmatemesis I will, on the whole leave the sigmoidoscope in the cupboard

Hastings.　GORDON FERGUSON

HYPOTHERMIA

SIR,—Your leading article last week suggests that surface cooling, while suitable for children, may not be the method of choice for adults

After watching surgical colleagues using surface cooling in their animal work, I have cooled two well-covered adult females for surgery of the aorta using simply ice-cold wet towels and two electric fans In the second case cooling to just below 30°C took less than $1^1/_2$ hours The simple cooling box ' under which blue children lie during surgery is used, and the method seems both simple and relatively quick when applied to adults

Postgraduate Medical School
of London, W 12.　JOHN BEARD

PREVENTION OF POLIOMYELITIS

SIR,—To return to the mysterious incidence of poliomyelitis and the suspicion that herpes virus may ward it off by having got there first I referred in my letter of Oct. 10 to Burnet s article [1] in which he showed that in Melbourne there was a normal incidence of herpetic infection among poliomyelitis patients and to Weyer s paper [2] which tells a very different story The most relevant passage of Weyer's is

> Of the sera available for examination from the standpoint of herpes antibody as reported above 27 were specimens drawn from children who proved to have been susceptible to poliomyelitis, all of them victims of the 1931 epidemic The bleedings were in most cases initial ones—i.e they were made upon diagnosis of poliomyelitis for the purpose of neutralisation tests with the virus of poliomyelitis. The results of the tests with herpes virus showed them to be individually and collectively devoid of any neutralising effect A comparison of the results with the incidence for herpes virus neutralisation in the same normal age groups gives:

Age group	*No of sera of non-polio patients*	*% neutralising herpes virus*	*No of sera of polio. patients*	*% neutralising herpes virus*
0–5	16	17	12	0
5–10	18	50	8	0
10–15	9	55	2	0
Age ?			5	0

As far as a mere G P can see, the great difference between Burnet's and Weyer's material was that Weyer got his much earlier in the poliomyelitis disease The whole subject could be of such vast importance that it simply weeps for investigation.

Only yesterday I came across a suggestive case history: a man of 21 contracted poliomyelitis, his elder brother had had it at the age of 14 the odds against this happening must be long but if some early influence common to both like the contracting or not contracting of herpes were a necessary factor for getting poliomyelitis the odds are much shorter

LACTIC ACID IN THE TREATMENT OF OSTEO ARTHRITIS

SIR,—The paper by Dr Lawrence (Oct 31) purports to be an objective analysis of 100 cases of osteo-arthritis of various joints; all the patients had physiotherapy and half of them were in addition, given injections of lactic acid. On the surface, the argument appears impressive but on closer examination it can be seen to contain a number of faulty assumptions sufficient to vitiate its conclusions

Dr Lawrence criticises the reports of treatment by myself and others mainly because there was "no comparison with other methods of treatment or with untreated cases ' At the risk of implying a ' tu quoque ' I must confess that for many years I have sought without success for a statistical account of the relative values of the different forms of physiotherapy in treatment and return to work—the only really valuable criterion—although many hundreds of thousands of patients must have been so treated: so the charge rebounds

There is a lack of precision in some parts of Dr Lawrence s article He says that ' standard methods of physiotherapy ' were used A great range of methods is available but no indication of what combination of these was employed is given Moreover there is evidence in the paper that Dr Lawrence does not recognise the important influence of rest and tissue support to the joint in the earlier weeks of injection treatment

All the patients were male employees of the National Coal Board : so the analysis was by no means a measure of the results of treatment in a cross section of the community, and therefore cannot be accepted as a competent assessment It is well recognised that by the nature of his calling and perhaps by his psychological approach the miner is the most difficult of workmen to refit for work

Although the response to any form of treatment varies greatly in different joints no information is given on which joints were treated beyond the statement that the knees were most frequently affected the hips next' : in fact the analysis seems to be based on the treatment of a jumble of joints Nor is there any evidence that an attempt was made to correlate the degree of severity and loss of function with the radiological findings—loss of joint space, lipping bony deformity, and cyst formation

On the question of the technique of injection any penetration of a joint by a needle involves some trauma, but the finer the needle, the less the damage: unless aspiration is called for the needle should be of the finest calibre I use size — 19 hypodermic needles for the smaller joints and needles of 0 55 mm bore for the larger joints If wider needles are used the fluid will usually show some degree of hæmarthrosis

Dr Lawrence surprisingly says that "the accuracy of the injection was readily determined by injecting 1 c cm. of air with the solution, when the characteristic gurgling sound could be heard on subsequent movement of the joint.' Does he really require this pump handle technique to assure himself that he has reached the cavity of the joint ? It seems to be an entirely unsurgical and unjustifiable procedure: let him mix 5 ml. of lactic acid with 2 ml. of joint effusion and a spot of blood in a test tube, shake it up and note the frothy flocculent mess that results. The greatest care should be taken to avoid injecting air along with the solution

There are many other points that might be alluded to—e.g the number of cases that show excess of fluid in the joint (in knees, 1 in 5) or the doubtful value in osteo arthritis of raised plasma viscosity (any significant rise can usually be found to be due to some coincident condition, such as pulmonary tuberculosis, cystitis, or boils)

Professor Tait, who held a chair of natural philosophy, demonstrated that by the laws of physics, it was impossible to drive a "gutty" golf ball more than 150 yards whereupon his son, Freddie, who was amateur champion, drove his ball 182 yards his father's comment was that it only went to prove that no scientist should make a dogmatic statement without reviewing his premises meticulously, and being his own severest critic I venture to commend this dictum to Dr Lawrence, and to suggest that his final sentence should, for the present, read "It is concluded that among miners, and in my hands, lactic acid has no therapeutic action in osteo arthritis"

Sunderland W GRANT WAUGH

PREVENTION OF BARBITURATE POISONING

SIR —A note in your issue of Oct 24 draws attention to the production of barbiturate tablets made safe by the addition of ipecacuanha alkaloids The fact that these tablets are now available must be especially welcome to doctors called upon to treat patients suffering from melancholia Insomnia is an essential feature of the depressive psychoses, and must be effectively treated prior to, or in the early stages of, electroconvulsion therapy In the past, it has been customary to give such patients an adequate supply of one of the barbiturates This has usually entailed the issue of a large number of barbiturate tablets, but not without some misgivings in the mind of the doctor

In this connection, it was disturbing to read that a practitioner was censured for allowing the issue of 40 'Seconal' capsules to a depressed patient[1] It seems reasonable to suppose that these new barbiturate preparations could be prescribed for depressed patients without fear of criticism from any source In practice, these tablets are unlikely to check for long the efforts of the suicidal subject implacably bent on his own destruction However, they would serve to prevent accidental poisoning and perhaps to baulk purely impulsive attempts at suicide

The principle underlying the manufacture of the new ipecacuanha-barbiturate tablets might be employed in other ways For example, the addition of ipecacuanha alkaloids to preparations of 'Chlorodyne' might prevent addiction

"CHEMOTHERAPEUTIC AGENT" AND "ANTIBIOTIC"

SIR,—The argument about the meaning of the word antibiotics must remind those with memories long enough of a similar argument about the word vitamins

Attempts to define vitamins have invariably failed, though Dr Leslie Harris probably came nearest to success (One recent definition is over eighty words long and contains the escape clause "as a rule" in its middle !) The reason for the failure is that each of the heterogeneous group of nutrients in question was in turn described as a vitamin by its discoverer, who did not stop to worry about definitions The word has a historical much more than a taxonomic significance Broadly speaking, all of the vitamins, at least all so far recognised, were discovered (or invented) between 1910 and 1950, some have fallen by the wayside—otherwise the number would be forbidding indeed

The analogy is even closer than at first might appear It is now generally recognised that a vitamin for one organism may not be a vitamin for another Is not precisely the same thing true of an antibiotic ? Provided we all know what we mean by antibiotics, does it really
matter whether chloramphenicol is or is not pu
the verbal pale merely because someone happens
synthesised it ? Supposing the synthesis (like
penicillin) had not proved to be commercially pr
and it had continued to be made by fermentatio
it have thereby retained the right to be called
biotic and have lost it merely because the
chemist and the chemical engineer successfully
synthesis on to the production plant ? It is rel
point out that ascorbic acid is still considered
vitamin though it has never been made commer
any route other than the synthetic The same
thiamine

I suggest that we continue to call antibioti
substances with the kind of property required,
by micro organisms (thus leaving out, for
purposes, any that may ultimately be extrac
higher plants), and discovered and investigate

DEFECTIVE ANÆSTHETIC MACHIN

SIR,—On several occasions recently my atten
been drawn to a possible cause of failure with g
'Trilene' analgesia machines for obstetrics, an
seen no mention of this in any of the literatur
subject The fault may lie in the expiratory val

I first noticed this when I was offered a Fr
apparatus, and in testing it I found that no
trilene could be detected when it was used in the
manner Minnitt's apparatus was used instead, a
wards it was found that the expiratory valv
Freedman's apparatus had been taken to piece
enthusiastic midwife and put back upside dow
next time I had to teach analgesia to midwives I
to this, and then discovered that the expirato
parts on the Minnitt's apparatus provided w
pletely absent At a routine check in a maternity
it was found that the expiratory valves were def
half the machines

An expiratory valve must admit air drawn thr
machine during inspiration and no air throug
It must open easily on expiration If air enters
the valve on inspiration the machine is render
pletely useless This will occur if the spring fail
the small check-plate back on to its seating
failure may be due to rust on the spring, a slight
displacement of the disc, or tampering with t
parts and wrong replacement of them What
cause may be, failure to function properly is o
very easily brought about and is likely to pass u
unless expressly looked for I am convinced th
machines should never be used unless the user p
checks the expiratory valve in every case This
done by compressing the concertina tubing in
hand whilst one inspires through the face piece (
hygienically, through the metal fitting over w
face-piece is applied) If it is impossible to ins
valve is functioning correctly, but if inspiration is
the valve must be defective and it should be r
at once or another machine should be used

This policy, if consistently pursued, would n
avert complete failure in a large number of cases
a great deal of avoidable pain to women in lab
on many occasions the precaution will be ove
A far better plan would be for instrument manu
to construct a sturdier expiratory valve which w
less easily damaged by rust, trauma, or m
handling That the success of a scientific ins
should depend on the precise accuracy of a
check valve about half an inch in diameter, an
metal spring, seems unfortunate If the makers
apparatus could construct one that is proof ag
hazards they would do a great service

---

[1] See *Lancet* 1953 i 1099

Meanwhile it behoves all who use these machines, and those who train midwives in their use and their care, to insist that the valve is *personally* checked before use in every case and that there are sufficient spare parts to make it possible instantly to replace one that is found to be defective.

INCISION FOR ACUTE APPENDICITIS

SIR,—Appendicitis is the most important condition in general surgery and it is pleasing to see well informed support for the muscle splitting incision Mr E R Flint, of Leeds, taught me that it was the correct incision for appendicectomy, and seventeen years of emergency surgery has confirmed his opinion

The snag is to know which cases are appendicitis A very large number of them may be diagnosed with overwhelming probability clinically but I wish to draw attention to an old but neglected confirmatory method. If one does a careful abdominal and sometimes pelvic examination under relaxing anæsthesia most inflamed appendixes may be felt It is then a simple matter to make a small incision locate the cæcal attachment of the organ, detach it, and gently dissect it out from base to tip In dirty cases it is necessary only to close the peritoneum The muscles come together by themselves and the scar is inconspicuous if made in the line of skin tension In such cases the paramedian incision rarely gives any information not obtainable through the muscle-split It is a damaging incision and largely responsible for the run on surgical belts It is best reserved for doubtful case where investigation has failed to establish *any alternative diagnosis* In these cases the operation is more correctly termed exploratory laparotomy

Hull.
J CLAPHAM COATES

SIR,—In this correspondence all the old arguments in favour of the different incisions have been brought up again, as has happened for so many years and doubtless each surgeon remains satisfied with the incision he continues to use Mr Donald's advice last week is good. The soundness of each incision depends mainly on the care taken in opening and closing the abdomen

I hope that no-one will be led away by the last paragraph in last week's letter from Mr Downie. To use a Pfannenstiel incision for acute appendicitis (when it is difficult to be sure whether suppuration or perforation is present) is surely unsound surgery

London, W.1
JOHN HOSFORD

PERIODIC MEDICAL OVERHAUL

SIR,—If the value of periodic medical overhaul be equated with utility in spotting disease then abundant experience of the subject exists For my part I have done periodic overhauls for over twenty years: sick people, reputedly healthy nursery babies, and, more recently, school-children three yearly overhauls yearly overhauls, monthly and even weekly overhauls One has certainly had time to make up one's mind

Although these examinations have differed in bias, I recognise no essential difference in the basic technique of routine examination of sick men and men loosely believed to be healthy At the end one finds that periodic overhaul is chiefly of value *in detecting non lethal* conditions, in assessing progress and in getting some knowledge of the patient but it seldom reveals our first signs of major disease—of the disease for instance that eventually kills the patient This last phase involves "starting prices and disease has a nasty habit of starting between overhauls Furthermore, those of us who have seen some of the subjects of our overhauls in the post-mortem room can recall many mortifying instances of human fallibility in diagnosis. Thus (if my initial postulate be accepted) the value of periodic overhaul is definite but not extensive

It is of course open to some who adopt a different criterion of value to claim that the benefit conferred on one myopic by provision of spectacles makes endless effort worth while

An attempt to assess the value of periodic overhaul in the prevention of disease is appallingly difficult if we insist on separating observation from imagination Unhappily much that is written about the more ambitious extensions of the preventive ideal—health education and positive health—wears an air of detachment from reality In health education the more one departs from the simplest matters, the more one ceases to make sense *Again there is a world of wisdom in Sir Adolphe* Abrahams's doubt as to whether a medical man is the best person to give health education That particular doubt is at least as old as Plutarch [1] As for positive health I suspect it is a mysticism and speaking in all humility, I have but a very limited understanding of mysticisms.

Middlesbrough.
JOHN CAHILL.

CHILDREN IN HOSPITAL

SIR,—Premedication of children before operation *can* be done efficiently but it often is not Tonsillectomy is the commonest operation of childhood but in many hospitals the children receive no premedication at all (apart from atropine) because of a desire to have the child conscious and coughing immediately after operation To terrify a child, perhaps giving him lasting psychological symptoms for the sake of a non life saving operation seems to me to show a distorted sense of proportions Adults would not tolerate the treatment children get, although in their case the fear is far less since they realise that what is being done is for their own good

Mr Clarkson's statement (Oct. 31) that ' premedication of children is one of the most important unsolved problems in modern anæsthesia ' cannot be true. If it is unsolved it is *the* most important problem

Oxford
DAVID PYKE

SIR—As an ear nose, and throat surgeon I am sure Dr Mac Keith's article (Oct 24) will prove most helpful to a good many housemen and nurses when they have digested its contents

I cannot help feeling however, that some of the statements might lead to confusion on first reading particularly in the minds of readers without an intimate knowledge of modern surgical techniques.

I am thinking in particular of the reference to Levy [2] whose statement gives the impression that operations for tonsillectomy are commonly done before the age of 1 or 2 I cannot believe that many surgeons today are operating on patients of this age.

The other point in question arises in the discussion of How the Doctor Can Help Most surgeons nowadays insist on preoperative sedatives, except for relatively minor operations such as myringotomy Surely few hospitals can have returned to the days when a child was led personally by the doctor away from his mother straight into the operating room to have his tonsils out!

London, W 1
IAN G ROBIN

SIR,—*Dr Lucas (Oct 31) states that children should reach the anæsthetic room prior to surgery either fast asleep or in complete possession of their faculties "*

Often either because of the nature of the surgical emergency or because the operation is to be a brief one carried out in an outpatient, premedication is of necessity restricted to atropine Again in my last hospital the distance between the E N T wards and the operating theatres has made the use of 'Nembutal' inadvisable in children about to have tonsillectomy For these children I have found the following method of induction most satisfactory

---

[1] Plutarch's Morals Part II. London 1684 p 106
[2] Levy D *Amer J Dis Child* 1945 69 7

If possible, the child is visited in the ward, the night before operation, and the anæsthetist then "makes friends" with him In an outpatient, this may have to be done in the few minutes preceding the induction. I tell the child that he is going to be told a story The great majority of children between the ages of 4 and 9 welcome this news Without saying anything about the anæsthetic, I then tell them a suitable fairy story or Rupert story After the first few sentences, the anæsthetic mask is placed about eight inches from the patient's head, and nitrous oxide allowed to flow at 10 litres per min. As the story progresses, so the mask is gradually brought a little closer to the face After about 5 minutes the child has usually lost consciousness, and it is possible to apply the mask to the face, and to add trichlorethylene, ether, or any other desired agent

Using this method, I found it possible to soothe most nervous children, and the great majority go to sleep without any sign of fear The only complaint has been that they did not hear the end of the story! Needless to say, this method of "premedication" is non toxic, and does not depress the reflexes It takes a little longer than other methods of induction, but I feel that the extra time spent is worth while

Alternatively, for children with visible veins, the technique of inducing with thiopentone, as described by Dr Bullough,[1] could hardly be improved With the use of a sharp needle, the child hardly feels the prick and goes to sleep quickly and safely

London, W C 1

ANDREW F FORBAT

SIR,—Following my letter in your issue of Nov 7 concerning the use of morphine in the postoperative treatment of children, I have had a request from a correspondent for further information concerning the formula I quoted—namely, age over age + 12 I would like to make it clear that this formula represents the fraction, according to the age of the child, of the official adult dose It does not represent the actual dose in grains

Black Notley Hospital
Braintree, Essex

M C WILKINSON

CORTISONE IN RHEUMATOID ARTHRITIS

SIR,—May I support strongly the sentiments expressed by Dr Copeman and Dr. Savage (Oct 17)? After an experience of twenty-five years in endocrinology, I looked upon the original claims for the therapeutic effects of cortisone and A C T.H with guarded optimism The present swing of the pendulum towards gloomy pessimism appears unwarranted, although not unusual The following case, of a patient known to Dr Savage and myself, illustrates the beneficial effect of small doses of cortisone in carefully selected patients even with a long history of rheumatoid arthritis, when other methods have failed completely

A woman, aged 51 (periods still regular), had a ten years' history of rheumatoid arthritis with moderate deformities of the fingers, wrists, knees, and ankles. In June, 1952 a recurrence began with swelling and pain, especially in ankles knees, and shoulders By August she could not leave her flat on the 2nd floor, because she could not manage the stairs. When seen by me in December, 1952, she was bedridden, immobilised and in continuous pain. Her erythrocyte sedimentation rate (E.S.R.) was between 68 and 80 mm (Westergren) after an hour Salicylates up to 12 g a day were without any effect, gold had caused untoward reactions in the past

By the end of February, 1953, she was receiving 25 mg of cortisone acetate daily with 3 g of (buffered) salicylates She has remained on that dosage to this day There was no dramatic change but a slow and steady improvement The pain has completely disappeared the deformities are the same as before the attack, but the swelling has gone Her appetite has become almost excessive, and she has stone in weight ; she now can manage 60 stairs and walk about 1 mile on the flat, slowly but fortably, and can do all the lighter housework cooking There have been no side-effects towards range and she appears mentally and

The story is the more remarkable, because for entirely personal reasons—could not be hospital, and biochemical examinations had to to a bare minimum Physiotherapy was given similarly restricted manner. The E.S.R. took over to decrease gradually to normal.

London, S W.3

V C

GOUT

SIR,—Dr Jennings's letter last week following questions

(1) Is interval therapy with gr 80 of sodium salicylate for 4 days per week sufficient to maintain the serum of gouty patients at a normal level, as has occur when gr 60–140 (usually gr. 90) of is given continuously ?

(2) Does interval therapy induce a favourable response in chronic gout, and if so, how does it that obtained by continuous therapy ?

(3) Does interval therapy induce loss continued therapy ?

(4) Should a high fluid intake be recommended ?

I suggest the following answers

(1) Dr Jennings's paper[2] stated "Our so far remained well as long as they have (sodium salicylate) in 80 gr doses daily for three or days a week Taken in this way it levels of blood uric acid" I take this to stopping salicylate therapy the serum uric acid return to abnormal levels within at least days Dr Jennings takes me to task for fact on a single patient, but I would perusal of the article will illustrate this point in and 6 which refer to 2 further patients. In my the serum uric acid almost invariably rises to levels within one to two days of stopping administration, even if this has been continued for months

It is unfortunate that Dr Jennings's paper did give sufficient serum uric acid figures to conclusions Bauer and Klemperer[3] were confirm them, and it appears that no such has ever been published

(2) Dr Jennings has presumably had interval therapy for at least sixteen of the many during which it has been advocated ment is often difficult to assess and it is not that, in the absence of really conclusive results therapy, there is divided opinion upon its degree It would appear that the subjective ment following continuous therapy, and detailed article under question, compares favourably published report with interval therapy

I would suggest that in those patients with radiological changes, repeated radiographs may objective evidence of response to therapy. It is significant that despite such considerable interval therapy there has not been a single radiological improvement, and yet within a few of continuous therapy it was possible to improvement in 3 patients[4]

(3) I find it difficult to believe that initial tration of sodium salicylate, in a dosage lower the serum uric acid appreciably, does not induce symptoms of salicylism. Graham[5] these symptoms were such as to make cinchophen a

his retirement there was still no faltering, no hesitation. To onlookers he appeared to be almost nervously excited, but his steps were accurate, and the patient's recovery and convalescence were normally smooth A memory of the 'rag and bottle' days of anæsthesia was his constant attention to the patient's respiration Not only to a junior resident anæsthetist would he lift his head from his own work to ask 'Is she breathing ?', but also to an experienced honorary anæsthetist, sometimes to his obvious surprise and even annoyance! His regard for the well being of the patient on the theatre table had the disadvantage that it prevented him from delegating work to which his juniors felt entitled as part of their educational experience Feeling that the responsibility was his, he feared to relax it

'While Stevens was an outstanding teacher and a sound gynæcologist, perhaps he excelled as an obstetrician Not only was he skilled in the manipulations which were needed in those days, but he had an uncanny insight into the woman in labour He taught non interference whenever possible, for he claimed, and rightly, that most women in the real "travail" of the slow hours of inertia will deliver themselves without injury or distress of the fœtus if left alone under the influence of sedatives.

"All his friends and colleagues knew him as a genial companion, always interested in talk and fun There was a sparkle in his eye which was a gesture of welcome on meeting, and an answer to the talk of men He was never so happy as when a member of a little group round a table exchanging experiences and witticisms, reacting with his own infectious laugh and perhaps another story

"His chief recreation was fishing, at which he claimed the moderate success of all fishermen, and indoors he would devote something of his leisure to painting at which, as an amateur self taught artist, he excelled

"There was one thing he could not tolerate, and that was humbug, whether in the work of members of the profession or in his residents or students He was impatient of insincerity and prevarication, but honesty and straightness he was immediately sympathetic What he expected from those around him was the most impressive part of his own simple and honest self He was not a man of academic brilliance nor given to speculation in theory, for his thought was restrained in imagination He was an essentially practical man, wholly reliable, a model of the strictest professional honesty, and a warm and generous friend"

Mr Stevens married Lizzie Jane, the eldest daughter of the late John Reeves, of Blackheath, and she survives him Their son, Mr Russell Stevens, is a surgeon in Dorchester

CONSTANTIN LEVADITI

Constantin Levaditi, who died on Sept 5 this year, was born in 1874 at Galatz in Rumania. He began his medical studies at Bucharest and later worked in Rumania under Prof V Babès In 1898 he went to Paris to work with Albert Charrin in C J Bouchard's laboratory Soon afterwards he became a naturalised Frenchman Next he studied experimental medicine and pharmacodynamics in the Ehrlich Institute in 1900, and later in the same year he moved to the Pasteur Institute, where he worked first under Metchnikoff, then under Roux, and finally as *chef de service* In 1902 he published two books on *Contributions à l'étude des mastzellen et de la mastzellen-leucocytose* and *Le leucocyte et ses granulations* In 1905 he published one on *Antitoxische Prozesse* His attention was early drawn to skin diseases (which led to the publication of *Ectodermoses neurotropes* in 1922 and *L'herpès et le zona, ectodermoses neurotropes* in 1926, and to his being awarded the Cameron prize in 1928) and subsequently to syphilis, to which he devoted himself from 1905 for many years, paying particular attention to the *Treponema pallidum* Soon after Schaudinn had discovered the ætiological rôle of this organism, Levaditi demonstrated, on May 17, 1905, its presence in a newborn baby with congenital syphilis and thus proved that syphilis could be inherited In 1909, with J Roché, Levaditi published *La syphilis expérimentation, microbiologie, diagnostic* In collaboration with Pierre Marie, Levaditi showed that the antigen used in Wassermann's reaction was non-specific and could be superseded by normal liver and by ox heart, and with T Yamanouchi he showed that the antigen was a hepatic lipid With R Sazerac in 1921 he demonstrated the therapeutic effect of sodium tartrobismuthate in syphilis In 1923 he published *Die Prophylaxie der Syphilis*, and in 1924 *Le bismuth dans le traitement de la syphilis* With A. Navarro-Martin he discovered the antisyphilitic and prophylactic effects of oral treatment with derivatives of pentavalent arsenic, especially 'Stovarsol' with Ernest Fourneau In 1930 he published *Prophylaxie de la syphilis, prophylaxie locale, préservati per os, métalloprévention* Levaditi, however, is perhaps most famous for his method of staining the treponema of syphilis with silver (in 1906)

Much more recently, Levaditi examined antibiotics for antisyphilitic action after J F. Mahoney, in 1943, had discovered that of penicillin, and he also studied Nelson's reaction At every stage of the fight against syphilis Levaditi was to the fore, but he also investigated viruses and found in 1910, with Karl Landsteiner, that poliomyelitis was due to a filtrable virus. This led to his well-known work on the viruses of epidemic encephalitis, herpes, rabies, and the Coxsackie viruses, and the publication, in 1938, with Pierre Lépine and others, of *Les ultravirus des maladies humaines*, in 1948, with other workers, *Les ultravirus des maladies animales*, in 1945 his *Précis de virologie médicale*, in 1948 *La streptomycine et ses applications thérapeutiques*, in 1950 *Antibiotiques d'origine fongique, bactérienne ou végétale* and in 1951 *Le chloramphénicol et ses applications thérapeutiques*

All Levaditi's hypotheses were put to experimental test, and all his experiments on animals were strictly controlled histologically (in 1949 he published *Images électroniques en microbiologie*) He served in a medical capacity throughout the 1914–18 war In June, 1928, he was elected honorary member of the Académie de Médecine, in honour of which occasion Dr R. Mamet contributed to the *Vie Médicale* (1928, 9, p 779) a biographical note which unfortunately was mistaken in the U S A for an obituary notice, with the result that the *Surgeon-General's Index*, the *Cumulative Index Medicus*, Dorland's *Medical Dictionary*, and E C Kelly's *Encyclopedia of Medical Sources* antedated Levaditi's demise by a quarter of a century

The British Social Biology Council (Tavistock House South, Tavistock Square, W C 1) express a somewhat austere attitude to Christmas in their photograph of a frozen lake in Buckinghamshire, but it is a good photograph, and the cards cost 6*s* 4*d* a dozen including envelopes and postage Some of their last year's cards (a photograph taken in the Forest of Fontainebleau) are also still to be had

The Grenfell Association (66, Victoria Street, London, S W 1) have carried on undefeatably their good medical work in Labrador and Northern Newfoundland Their well known cards include photographs and drawings of Labrador snow scenes, as well as several gently sentimental Christmas subjects Among these a new one, nicely designed by Betty Fyfe, shows an Eskimo child wrapped up to the nines, and a very young cherub in nothing but a nightshirt together decorating a Christmas tree out of doors on a cold night The cards are of different prices, ranging from 6*d* to 1*s* 9*d*, and are sold separately

A newcomer to this column is the National Spastics Society (44, Stratford Road, London, W 8) Their cards are in the old coach inn yard waits hunting lychgate tradition, and why not? A packet of 6 cards accompanied by six Christmas seals costs 2*s* 6*d* for the ordinary kind, or 4*s* for full colour reproductions with gold deckle edge and a ribbon. Perhaps when the society is a little older it will find an artist to express more personally its special good cause, but this is a start

PLAGUE OF FLIES

FOR the past few months swarms of flies have been causing much concern at seaside towns on the South Coast They have now been identified by the British Museum as two species of the genus cœlopa—*C frigida* and *C pilipes*[1] They usually prefer a warmer climate, but they have evidently been attracted by the great quantities of seaweed that have lately been washed ashore at several places on the South Coast These flies, which are black brown and bristly, are thought to breed exclusively in decaying seaweed, so it is hard to explain their recent appearance in London[2] They are attracted by certain smells, such as those of trichorethylene and chloroform, dry cleaners and chemists have reported troublesome invasions of their premises, though anæsthetists, it seems, have so far escaped There is disagreement among entomologists about the eating habits of these unpleasant creatures, but some say they are much addicted to beer Spraying with insecticides helps to keep down their numbers, but until the London plague is traced to its source it is unlikely that the flies will disappear Local authorities on the South Coast have decided to ask for Government help in dealing with the flies and the seaweed they thrive on

FAMILY PLANNING ASSOCIATION

THE second medical conference of the Family Planning Association was held in London on Nov 7

Dr M C Marwick and Dr E Wachtel described the technique and results of histological examination of material aspirated from the posterior fornix or scraped from the cervix with a wooden spatula As part of the routine of a birth control clinic, material has been collected in this way, spread on a glass slide fixed, stained, and forwarded to a cytological laboratory Malignant cells from various parts of the genital tract have been seen at a time when there was no clinical indication of disease, and also abnormal cells whose significance is not yet clear

Dr S M Dawkins said that in clinics the danger of the obviously infected patient was small compared with that of the symptomless carrier The major hazards of cross infection were not from instruments and caps which were always boiled, but from hands gloves, taps, soap bowls, and towels, and even from the tubes of the lubricating jelly used in some clinics Where antiseptics were used, care should be taken that these were suitable for the purpose and were used in the right concentration, and that the article was immersed long enough Plenty of soap and water was still one of the best antiseptics Dr Dawkins advocated the methods of cleansing and sterilisation described in the Medical Research Council's memorandum no 11 and war memorandum no 6

The meeting heard an account of the association's work in examining contraceptive devices submitted by manufacturers, and in issuing a list[3] of approved contraceptive creams whose spermicidal efficiency has been tested by bio assay

BRITISH MEDICAL STUDENTS' ASSOCIATION

THE annual general meeting of this association was held in Bristol on Nov 5, 6, and 7, and was attended by 5 delegates Prof G Gordon Lennon was inaugurated as his president

In a discussion on student health it was announced that the British Student Tuberculosis Foundation had provided tuition and convalescent care for 26 students suffering from tuberculosis, at its pilot centre at Pinewood, Berks There was also a waiting-list of 20 The foundation hopes to set up a larger, permanent centre A speaker pointed out that a student could be exempted, if he chose, from National Insurance contribution Even if he wished, however, he was unable to make any contribution other than as an unemployed person, and was thus debarred from any benefit if he fell ill

The next annual general meeting will be held in London in November, 1954

LEBANON HOSPITAL

FOUNDED in 1898, the Lebanon Hospital for Mental and Nervous Disorders at Asfuriyeh, Beirut, is still expanding; and in April this year a new treatment centre and nervous disorders unit was opened The hospital's report for 1952 shows that during the year 598 patients were admitted, and 575 discharged, and the daily average of patients in the hospital was 420 The number of applicants for the psychiatric nurses' training school, founded in 1948, is steadily increasing, and 16 first-year nurses were enrolled during the year The school has also launched a course for nurses who have graduated from various Middle East training schools in general nursing and who wish to take the Asfuriyeh certificate after one year of intensive training During the year the hospital received important additions to its staff In London, at the end of the year, Miss R Harvey became general secretary in succession to Miss Hilda Fox, who has retired after twenty seven years in this appointment

EXPERIMENTS ON ANIMALS

DURING 1952, according to the Home Office returns 2,117,912 experiments were made on living animals Of these 1,836 328 (86 6%) were made without anæsthetics. These experiments were mostly inoculations, modifications of the animals' environment or diet, or the administration of a drug or toxin The results of many of these experiments were negative and the animal suffered no harmful effects. Of the total experiments 95,901 were made in the course of cancer research, 202,435 for the purposes of public health or directly for the diagnosis of disease, and 810,676 for the standardisation of sera, vaccines, and drugs During the year 1348 visits mostly without previous notice, were paid by inspectors to registered laboratories The inspectors also visited 5 premises proposed for registration

TELEVISION AND THE FAMILY

THE Coventry Tutorial Class in Psychology, who reported last year on The Adolescent and Television,[3] have made a further investigation[4] this time into the impact of television on the family Their conclusions are so warmly in favour of this form of entertainment that it seems just possible that Mr Max Gordon, the tutor, and the engineer, the schoolmaster, the secretary, the education welfare officer, and the clerical officer who compose the group, are themselves keen televiewers They have, however, done their best to collect unbiased information by means of a questionnary distributed through primary and secondary schools situated in districts of the greatest possible variety The heads of the schools gave out the questionaries to children whose parents had a television set, telling them to ask their fathers to fill them up, if they were willing In this way, 1000 questionaries were distributed, and 250 were returned completed The group estimate that this represents a response from 1 in every 100 families with television sets in Coventry, and that it is a fair cross section

The first six questions (answered by the father in every case) asked how long the father had been a regular viewer, how long he had been married how many of his children lived at

7 30 P.M Dr R. R. Willcox Mr A. J King - For and
Treatment Before Diagnosis

Clearly in neurology, as in other specialties, some of the day-to day work must be done by those who have not the specialist's special training, but it is the task of the clinical neurologist to maintain standards, and by teaching and personal contacts to make his colleagues aware of developments in his particular field, so that not only is their own work more discriminating but they become increasingly able to recognise when his help would be valuable Consequently the need for the clinical neurologist in the ordinary practice of medicine has never been so great as it is today

Research

Now I turn to the prospects of research in clinical neurology In the development of new ideas the relationship between observation and hypothesis is an intimate one, for not only do observations suggest a new hypothesis, but often a new hypothesis points to fruitful new observations In this sphere, also, it would be artificial to distinguish clinical observations from those made by other methods, and in the sphere of research the number and variety of such ancillary observations is considerably greater than in neurological diagnosis, because it includes animal experiments Up to the end of last century the great clinical neurologists were limited in constructing their hypotheses to correlating their clinical observations with the lesions revealed by pathology and with the very limited knowledge of neurophysiology then available The work of such a man as Hughlings Jackson illustrates what rich and fruitful ideas the mind of a genius could evolve from these limited types of observation, and I believe that what I may perhaps call the Jacksonian method is still rich in possibilities

Much work remains to be done in the sphere of aphasia and in the interpretation of those perceptual disorders which impair the recognition of objects, and the awareness of space and of the body Our knowledge of these subjects has been greatly enriched during recent years by many new observations, but in considering these difficult questions we need perhaps fresh unifying concepts which will enable us to see some common pattern of disordered function underlying disorders of thought, speech, and recognition, and also will clarify the idea of cerebral localisation Here the neurologist has a unique contribution to make to the illumination of the brain-mind relationship

Today, indeed, there is no sharp distinction between neurology and psychiatry, for they share an interest in the neurological basis of all aspects of mind. We recognise this overlap alike in our daily practice and in the great contributions which neurology has made to psychiatric therapeutics I believe that the fertility of the marriage between the two specialties is far from exhausted

FRESH TECHNIQUES OF OBSERVATION

Now let us turn to the new avenues for research which have been opened by the fresh techniques of observation which have been developed during the present century and, more particularly, during the last twenty five years Two of the most impressive of these, of course, are electro encephalography and the various forms of neuroradiology It seems to me that the great advances so far made by electro-encephalography have been even more important for theory than for practice, and this is true especially of neurophysiology If we look at the recent development in our knowledge of epilepsy, it is fascinating to see how clinical observation, clinical electro-encephalography, and neurophysiological electro-encephalography have blended to give us already the outline of a conception of a central mechanism regulating consciousness. This is [illegible] by the observations of Penfield on highest [illegible] the work of Magoun and his colleagues on [illegible] reticular activating system and that of Jasper and Droogleever-Fortuyn on the experim production of a petit-mal type of dysrhythmia. B should be noted that it is clinical neurology provides the inspiration for this work, for it is in alone that the psychological content of highest seizures can be studied and it is in man that petit can best be observed Consequently it is only in as the clinical neurologist by his observations is ab differentiate different types of epileptic attack th provides the material for the construction of hypot to which the observations of the electro-encephalogr and the neurophysiologist contribute

There are two further fruitful developments of researches The hypothesis of the rôle of the ce reticular formation in the control of consciousness application in the clinical study and differentiati prolonged disturbances of consciousness—i.e., stat stupor and coma, to which some neurosurgeons example, Cairns, Jefferson, and Obrador, have particular attention Abnormal states of sleep, drea and the hallucinoses constitute a closely related fi study, and in the experimental investigation of the of action of the hallucinogenic drugs neurology, ps logy, electro encephalography, and pharmacology hands with psychiatry in a piece of work which not is of great intrinsic interest, but may throw valuable upon the symptomatology of the psychoses, partic schizophrenia

BIOCHEMISTRY OF THE NERVOUS SYSTEM

Finally, I come to a field which, at first sight, may more remote from clinical neurology than those which I have so far touched, I mean the biocher Cajal, you will remember, in the passage I have al quoted, sought as an ultimate scientific objectiv physico chemical representation of events The litt have already learnt about the biochemistry of nervous system has been enough to show the impor of this subject in the interpretation of all neurol phenomena The biochemistry of the vitamins o B group has revealed something of the complexity o intracellular enzyme processes in the nervous sys and, after all, all pathological changes are fundamen physico-chemical changes Hence the biochemistr the nerve cell enters not only into those disorders w are commonly called metabolic, but also into its rea to infections and the processes of resistance and im nity, into the care of the comatose patient, the dea survival of cells after vascular occlusion, and the degenerations which are either hereditary in orig associated with the process of ageing If we add to t the biochemistry of the synapse, whether within nervous system itself or in the autonomic ganglia, o myoneural junction, and of the metabolism of muscles themselves, the significance of biochemistry neurology needs no emphasis

What I would emphasise, however, is the part t played by the clinical neurologist in the biochem field. It is not often that he will himself be an ex biochemist, but he must surely be sufficiently in t with what is going on in the biochemistry of the ner system, not merely to work in fruitful collaboration the biochemist, but to be able to suggest to his biochem colleagues promising fields of research Biochem research in neurology always begins either because clinical neurologist asks the biochemist a question because he presents the facts of clinical neurology to biochemist in such a way that the biochemist him asks the question

Take myasthenia as an example The discovery of value of physostigmine and all the knowledge that flowed from it was based upon a clinical observat The thymus was brought into the picture by the pat st, but only because he discovered abnormalities in thymus in patients already labelled as suffering from sthenia by the clinician. From this sprang thymec y and the observations of pharmacologists and iologists on a possible relationship between the mus gland and the myoneural junction Essential ugh the contributions of the non-clinical scientists are he solution of the problem, I do not believe that the k of the clinical neurologist is therefore finished king broadly at the clinical picture he may well ask self whether myasthenia is a single entity—whether act it is a disease or a symptom, whether there is h a thing as thyrotoxic myasthenia as well as an ciation between thyrotoxicosis and myasthenia vis, and where in the picture are to be placed the sthenic syndromes associated with avitaminosis and h carcinoma of the lung In other words the contri ons which the pathologist and the biochemist are king to the building up of the hypothesis about sthenia should stimulate the clinician to discriminate ther in his own field.

nd so one might multiply instances the various ms of polyneuritis, motor neurone disease, dissemi ed sclerosis, parkinsonism of the degenerative type, n epilepsy itself at once suggest themselves as fields research where the clinical neurologist with a wledge of the possibilities of biochemistry may e a contribution which he alone has the power to ke.

The relationship between the metabolism of the vous system and that of the rest of the body is still ost uncharted territory How rich it is in possibilities hown by recent research on the metabolism of copper d the amino-acids in Wilson's disease, and this also ws how important are the links between neurology d internal medicine.

A Challenge

I have but touched the fringe of a vast subject, but hope I have said enough to convince you that the spects for clinical neurology were never brighter than y are today Let me conclude with some words of ful which are both an encouragement and a challenge s, his successors:

"Great men are at times geniuses, occasionally children, t always incomplete. Even granting that the genius jected to the test of critical inspection emerges free from error we should consider that everything that he has covered in a given domain is almost nothing in comparison th what is left to be discovered. Nature offers to all of us xhaustible wealth, and we have no cause to envy those who ceded us, nor to exclaim as did Alexander in consequence the victories of Philip: My father is going to leave me thing to conquer!"

The long words of science are justified because they unfamiliar This seems to be a doubtful recommendation d one which suggests that the scientist takes a pride in ning pages that are deliberately obscure. This is not so e apparent unfamiliarity of scientific words, the air they are of belonging to a specialised type of thought and language, ts them apart, in some way from the speech of everyday e. This is an advantage to the users of both languages. tepless and amorphous are literally the same sleeplessness es not seem to be very different from insomnia, yet in each e both words have their appropriate uses, and the English nguage is the richer because both are available It is not ue to say that either language can be translated into or placed by the other without loss. The loss may be small, d hypogeal is replaced by underground it is much greater if ypostatic is translated into understanding It may even be complete. Kipling once told us that,

> The Colonel's Lady an' Judy O'Grady
> Are sisters under their skins.

His meaning is lost if a scientist describes them as subcutaneous siblings."—T H. Savory *The Language of Science*. London, 1953, p. 184.

II STATEMENT AND TESTING OF PROVISIONAL HYPOTHESIS

The suggestion emerged from part I of this paper that physical activity in work is associated with a lower incidence and severity of coronary (ischæmic) heart-disease in middle-aged men This proposition is interesting in view of the present dearth of useful theories on the causes of coronary heart-disease and of its probable increase The possibility that the association may be a causal one, and that factors of *low* incidence and mortality may be identified in occupation, is worth pursuing in the hope of eventually discovering clues to the prevention of the disease. As has so often happened in epidemiology clues may be discovered before the intimate processes of the disease are fully understood. We therefore adopted the suggestion as a working hypothesis, and proceeded to test it as best we could. The provisional hypothesis may be stated, as an association between variables, thus:

> Men in physically active jobs have a lower incidence of coronary heart-disease in middle age than have men in physically inactive jobs. More important, the disease is not so severe in physically active workers, tending to present first in them as angina pectoris and other relatively benign forms, and to have a smaller early case-fatality and a lower early mortality rate.

Since there was no indication that the greater incidence and severity of coronary heart-disease in the physically less active workers was associated particularly with mental factors in their work and for other reasons, no alternative hypotheses were framed for the present in psychological terms and the observations were confined as far as possible to the dimension of physical activity and inactivity of work The hypothesis, thus is not advanced in any exclusive sense it was necessary, however to try to isolate it if any progress was to be made.

Methods Adopted in Testing the Hypothesis

In this type of research dealing as it often must with material impossible to control," of less accuracy than might be wished and from which it is difficult to isolate variables, *special precautions need to be taken by the investigator* In the present instance reliance was placed on the power of simultaneous attack on the problem from different directions and independent bodies of material were used so that the cumulative effect (as well as individual findings that may by themselves lack conviction) can be considered

Attempts have been made to test the provisional hypothesis by observing its capacity to predict in a variety of situations. The following tests were carried out

First test.—Enlarging the evidence by a further period of observation of the experience from which the original observation was made (London Transport and the Post Office)

Second test.—Extending the hypothesis from early to all coronary mortality and observing the national experience

of twenty years ago, described in the Registrar General's Occupational Mortality Supplement

Third test—Making deductions from the hypothesis in terms of the course of coronary heart disease as well as its incidence and mode of presentation, and trying to verify these on yet another set of data—a current sample of death certificates

First Test (Direct Confirmation) Further Observation of Transport and Postal Workers

The information in part I covers the years 1949–50, and it was mostly collected by the middle of 1951 The analysis, however, could not be undertaken until 1952, and by this time it was impracticable to collect detailed morbidity data for 1951 and 1952, highly desirable though this was now seen to be The deaths, however, that occurred during those years were recorded in the Central Record of Staff Statistics of London Transport Executive, and the Post Office has for many years kept records of the mortality of its staff Since the lower death-rates of the conductors and postmen during the first days and weeks of clinical coronary heart-disease were the main findings in 1949–50 it was clearly important to know whether these workers maintained their advantage in 1951–52, particularly since wide variations in mortality-rates from year to year are commonly found in this type of study even when dealing with substantially larger numbers of cases than we have been able to do

Table VII(A) gives the early mortality rates from coronary heart-disease among the drivers and conductors of the central ("red") buses in 1951–52 (The figures for tram and trolleybus drivers and conductors are not shown in table VII because the trams were being withdrawn during 1951) The drivers have a higher mortality in each ten-year age group during 1951–52 (in each five year group also) and the standardised rate summarises the excess as 90% This was little different from the findings in 1949–50, the greater excess shown in the middle columns of table IV being mainly due to the particularly low mortality among the tram and trolleybus conductors

Table VII(B) amalgamates the experience of the central bus workers for the four years by adding and averaging the deaths and population figures over 1949–52 The 'immediate mortality" of the drivers is seen to be about twice that of the conductors, and mortality in the rest of the first three months is about two thirds higher, total early mortality is over 80% as much again in the drivers as in the conductors

Table VIII(A) describes the early mortality among the five postal grades during 1951–52 The Civil Service executives and clerks were not studied in 1951–52, so, unfortunatel only one truly sedentary grade remains—the telephon In 1951–52, as in 1949–50, the postmen had a substanti lower early mortality than the telephonists, comparis with the three "intermediate" grades are again of lit interest The combined rate for 1949–52 in table VIII(B) sho the by now expected trend (fig 2)

Summing up in 1951–52 the physically more acti workers (conductors and postmen) had lower ear mortality-rates than the physically less active worke (drivers and telephonists, respectively) Enlargeme of the evidence by two further years' experience therefor supports the hypothesis

The next test should be to repeat these special observa tions in different groups of workers, but this would me

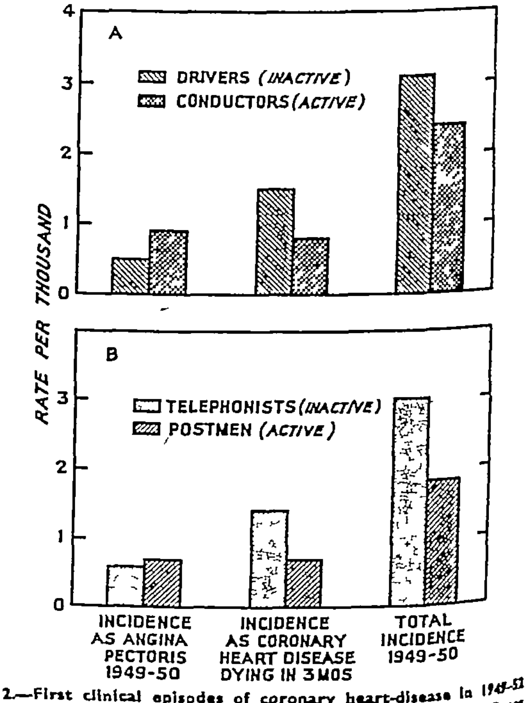

Fig 2.—First clinical episodes of coronary heart-disease in 1949-51: A, drivers and male conductors, aged 35–64, of Central London Buses, B G P O male telephonists and postmen, aged 35–59

lay of some years before results could be available therefore turned to data already available, such having the merits and drawbacks of being collected quite other purposes.(c)

ond Test Physical Activity of Work, and the Death rate from Coronary Heart disease

has been postulated, as the most important part he hypothesis to be tested, that the "early mortality" coronary heart-disease—death in the first three ths of the clinical disease—is lower in middle-aged in physically active jobs than in men doing physically tive work. But it has previously been suggested his series[14] that this early mortality is responsible about three-quarters of the coronary deaths in ddle age.(d) The present postulate may thus be ended to include *all* coronary deaths

That men doing physically active work have a lower mortality from coronary heart-disease in middle age than men in less active work.

test of this extended hypothesis will be a test though rhaps not a rigorous one, of the original hypothesis. It was decided therefore to make a special analysis the mortality from coronary heart-disease in the rious occupations for which data are available in the gistrar-General's Occupational Mortality Volume of e Decennial Supplement for 1930–32[17] the latest nd only) years that could be studied "Coronary rombosis" was beginning to be commonly diagnosed this country late in the 1920s,[18] so the analysis is making

METHOD

It is very difficult to differentiate between the occupational oups of social class I (the leading professions managers, ners, &c.) or of social class II ("lesser" professions, &c.) terms of the physical work they involve. We therefore amined social classes III (skilled workers) IV (semi-skilled rkers), and V (unskilled workers) which include a wide riety of heavy and light jobs. There are mortality data for occupational "groups" in these three classes (excluding e Armed Forces) and they contain over 2½ million men ed 45–64 years—the great majority of all the men in these sses.

They used three categories:

Categories	Groups	No of men
A Physically heavy jobs	16	670 465
B Physically light jobs	23	546 012
C Intermediate and doubtful jobs—i.e., jobs which were both heavy and light or neither; about which the referees disagreed or which they were unable to to classify	31	1 400 549
Total	70	2 617 026

(The contents of the categories are detailed elsewhere[19]) We then sorted the groups into their social classes, and calculated death rates for coronary heart-disease.

We do not in our unit have the necessary knowledge to make an informed grading of these occupation groups to heavy and light work, especially for as long ago as 1930–32. And for a different reason, also we invited others to make the classification for us It is important in this kind of inquiry to take precautions against any recognisable source of "bias": in the present instance the grading of jobs should obviously be "blind," so that in cases of doubt the decision whether a job is heavy or light in respect of physical activity cannot be affected by knowledge of what is happening to the other variable being studied—coronary mortality We therefore requested two colleagues, experts in industrial medicine to classify the occupation groups—without telling them our hypothesis or indeed, what problem we were investigating They kindly agreed and, in addition, they did the grading independently consulting together only at the end over a few doubtful groups.

TABLE IX—MORTALITY FROM CORONARY HEART-DISEASE IN HEAVY AND LIGHT WORKERS (MEN AGED 45–54) ENGLAND AND WALES, 1930–32

Average Annual Death-rates per 1,000 000

Social class	Physical demands of work		
	Heavy	Intermediate and doubtful	Light
III	*172*	*225*	*341*

Mixed	*78*		*265*
Total classes III IV and V	*139*	*239*	*337*
Total no of deaths (3 years)	154	531	321
1931 Census population ×3	1 110,390	2,303 772	951 732
Men Aged 55–64			
III	*497*	*608*	*916*
IV	*353*	*468*	*556*
V	*363*	*490*	*738*
Mixed	*259*		*561*
Total classes III, IV and V	*396*	*530*	*866*
Total no. of deaths (3 years)	357	983	519
1931 Census population ×3	901 006	1 855 675	668,304

Death-rates calculated from information given in table 4A of the Registrar-General's Decennial Supplement, part IIa (1938).[17]
Deaths are those certified to no 94 of the Fourth Revision of the *International List of Causes of Death*, 1929
The classification of occupation groups was specially made.

The rates for classes III IV and V combined at other ages were:

Ages (years)	Heavy	Intermediate and doubtful	Light
35–44	*46*	*61*	*61*
65–69	*859*	*1137*	*1745*
70–74	*13 7*	*1501*	*2307*

(c) The first two authors alone are responsible for the remainder of this paper

(d) This study[14] showed that 70% of all coronary *deaths* during the years 1940–50 among a group of medical practitioners, aged 40–64, took place in the first month of the first clinical attack of the disease; the majority of these being deaths in the first few days (here called "immediate").

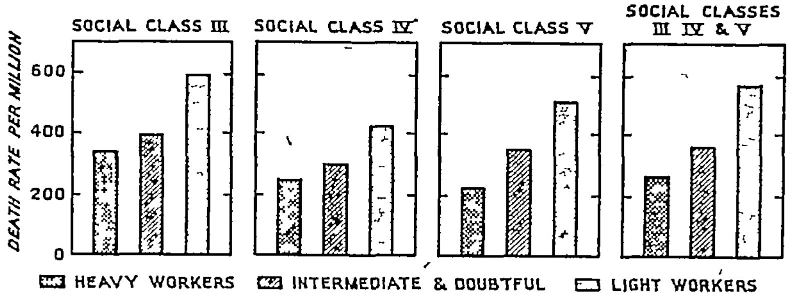

Fig 3—Mortality from coronary heart-disease in heavy and light workers, men aged 45–64, in England and Wales in 1930–32.

RESULTS

The results are shown in table IX and summarised in fig 3. In brief, the coronary mortality of the groups doing physically heavy work is rather less than half that of the light groups. The advantage of the heavy workers is seen at ages 45–54 and 55–64 separately, and in the social classes individually. As satisfactory (technically speaking!) as this finding, which supports the hypothesis, is the central placing of the intermediate and doubtful groups, and the strong "trend" shown in the figures. Moreover, the fact that the excess mortality of the light occupation groups is no more evident among the skilled men of social class III than in the semi skilled workers of social class IV and the unskilled workers of class V does not suggest that there is an important psychological strain involved in the light occupations which might be responsible for *their* excess mortality. These jobs in classes IV and V—skilled workers in gas works service, metal machinists, metal glazers, &c., barmen, printing-machine minders, printers, &c., messengers and porters (excluding railway, &c., porters)—do not obviously involve "responsibility" or special "brainwork," however much some light jobs of social class III may or may not be saturated with psychological stress factors. Fig 4 plots the mortality rates of occupation groups with an average of 10 or more deaths per year, and shows almost no overlap of heavy and light groups. If there is a major psychological influence operating to produce the mortality gradient of table IX, the scatter of fig 4 suggests that it is so intimately associated with the physical factor as not to be readily distinguishable from it.

DISCUSSION

The validity of this test depends on several things, including the classification of the occupations. We cannot at the moment do anything about that. Of another order is the difficulty which arises because men may change their jobs on account of illness. They may be advised, for instance, to transfer from heavy work to light for the sake of their health, and the mortality-rates in light jobs may thus be exaggerated. (Certain low skilled light jobs indeed are often reserved for the infirm.) This is one disadvantage of having to accept the last occupation before death as a sufficient indicator of a man's main occupation during his life. As already indicated, however, this problem is unlikely to be critical in the present instance, because a majority of all deaths from coronary disease in middle aged men probably occurs in the first clinical episode of the disease—i e, *before* there is opportunity to change jobs on account of it. The distribution of deaths in the doctors has already been mentioned. The standard of diagnosis in these doctors is likely to be particularly high, and premonitory clinical manifestations of coronary heart-disease, mild or atypical as well as typical, are far likelier to have been diagnosed among them in 1940–50 than in the general population in 1930–32. Yet, as has been said, in almost three quarters of the coronary deaths among the doctors there was no record of illness (lasting as much as a week) due to coronary heart disease before the first reported and fatal attack.

Two further pieces of evidence may be mentioned in support of this proposition.

(1) In a representative sample of death certificates obtained for another inquiry and referring to March, 1952, there were, in men aged 45–74 years, 118 deaths from coronary heart-disease about which some clinical information was available. From this information it appeared that 83 (70%) of the deaths had probably occurred in first clinical episodes of the disease, and 35 probably in second or later episodes. This material will be discussed more fully in the next test of the hypothesis.

(2) A group of light occupations which are highly specialised and require considerable skill and training was isolated from social class III in the Registrar-General's occupational mortality data. Such occupations are potter, compositor, french polisher, railway engine driver, railway signalman, and the police. It is very unlikely that middle aged men will transfer to these occupations because they are suffering from coronary heart-disease, or one of its precursors (or even from ill health not considered at the time to be related to coronary heart-

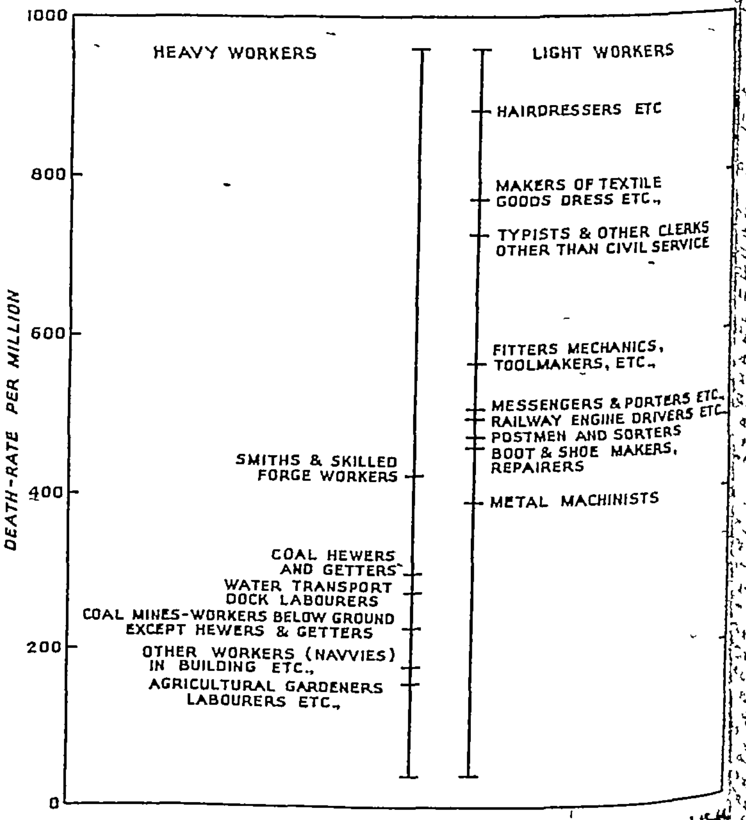

Fig 4—Mortality from coronary heart-disease in heavy and light workers men aged 45–64 in England and Wales in 1930–32. Rates for occupation groups in social classes III, IV and V having 10 or more deaths per year

ae). Moreover certain of these occupations will require -employment medical examination The mortality from ary *heart disease* in this *special* group of light occupa was found to be substantially greater than in the heavy ers of social class III, and this excess was apparent from 4 through 70–74 years of age. This is evidence of course about one side of the problem—that light workers have h mortality

he only alternative explanation we can think of which it account for the trend of table IX is that since y workers live often in villages and small towns light workers in cities where medical facilities have been better the diagnosis of coronary heart se—still a relatively 'new' condition in 1930–32— ht have been more readily made in light workers vever in the years under consideration, mortality as commonly ascribed to so-called myocardial e in light workers as in heavy workers, and this ers unlikely an explanation depending mainly on the ity of diagnosis and certification It will be interest to observe the trends of occupational mortality een 1930–32 and 1949–53 when figures for these er years become available and this may provide ther test of the hypothesis (The suggestion from the minary figures for 1949[10] is that the difference een heavy and light workers will be less than in)–32.)

umming up, therefore it appears that coronary tality as a whole in each of social classes III IV and V lower during middle age among heavy than light kers, and the hypothesis has been supported and nded This test has one considerable advantage r the first, for it provides information about categories work—heavy and light—and not merely about vidual jobs It may also be added that the excess mortality with light work is more striking in coronary rt-disease than in any of the other causes of death which the Registrar General provides data.(4)

ird Test: Physical Activity of Work and the Natural History of Coronary Heart disease

o far, these investigations have begun with *occupa al groups* involving various degrees of physical activity and have observed the rate of occurrence of cases of coronary heart-disease in them We next tried to test the hypothesis from the opposite direction by collecting *cases* of coronary heart-disease and observing their distribution among men with various degrees of physical activity in their jobs

TABLE X—MORTALITY OF HEAVY AND LIGHT WORKERS (MEN AGED 45–64 INCLUSIVE) ENGLAND AND WALES, 1930–32. SOCIAL CLASSES III, IV AND V COMBINED

See footnotes to table IX and ref 13

Coronary heart-disease of middle aged men may be regarded clinically as a 'spectrum' Cases first presenting as angina pectoris belong to the benign and chronic end of the spectrum those dying in the first clinical episode of coronary thrombosis represent the other extreme of malignancy and acuteness; and between these two which may be regarded at this level of abstraction as 'minimal' and 'maximal' modes of first attack, there are various grades and stages. (The justification for such an approach lies in the unitary pathology structural and functional, of ischæmic heart-disease and in the varying prognosis in different clinical types of it.) Similarly, with deaths from coronary heart-disease deaths in *later* clinical episodes represent a more benign and chronic type of disease than do deaths in *first* clinical episodes Regarding the spectrum in terms of the present hypothesis, it may be postulated that the physical component of their work affects the chances that middle-aged men will suffer from coronary heart-disease—i.e, will get on to the spectrum (the incidence) and also how they will fare what type of disease they will suffer, and when they will die, if they do get on to it.

We may be able later to test the hypothesis in hospital outpatient departments and wards on patients with coronary *heart-disease* but this will be difficult for many technical reasons connected with the characteristic unrepresentativeness of hospital data. Meanwhile we are limiting ourselves to a preliminary consideration of *deaths* from coronary heart disease and to quite simple approaches to the natural history of the disease in terms of the mode of first presentation and the subsequent course.

HYPOTHESIS AND DEDUCTION

In heavy workers, it is postulated, the first clinical episode of coronary heart-disease is particularly likely to take the form of angina (or other relatively benign manifestation) and heavy workers are therefore less likely than light workers to die in their first episode Now coronary heart-disease is a chronic relapsing condition and men who have recovered from a *first* episode of it are liable to have later attacks in one of which they will die. If the heavier workers have a more benign form of onset and a lower case-fatality in their first episode than light workers, as the hypothesis affirms

---

Analyses in these terms of heavy occupation groups and light is not particularly rewarding with other cardiovascular and related conditions Table X summarises the findings.

"There is a heavy/light trend in mortality from 'nephritis'—probably much of it hypertension[18] and a much stronger one in diabetes; but it is impossible to be as sure in these conditions as with coronary disease that the greater mortalities in the light occupations are not due in substantial part to inflation of the rates by transfer of sick men from heavier jobs. Nephritis fails on the trial of the special group of light occupations though diabetes mortality passes this trial. Many of the diabetes deaths which, because of the coding rules then in force, are best regarded as deaths in diabetic men rather than deaths from diabetes may well have been due to coronary disease and the gradient of mortality with physical activity in diabetes, may therefore be a further support of the main hypothesis (see also Joslin[3])

In the other conditions included in the table the excess mortality in the Intermediate and Doubtful column suggests that the approach is wrong that the material has been cut, so to speak, against the grain. This may be because physical activity in work is not relevant to the ætiology whatever it may be, of these conditions; or because these conditions have led to much job-changing —from heavy work to less heavy *for example* or from more skilled lighter jobs to less skilled heavier ones.

We thought of another test of the hypothesis along these lines—that the incidence of coronary heart-disease should be *inversely* correlated with conditions which are commoner in heavy workers. That this test might be useful is indicated by the Registrar General's occupational mortality data, which show an inverse relation between deaths from coronary heart-disease and deaths from accidents.[11]

they are thus more likely to have the disease in a chronic form—to suffer later episodes, and to die in a later episode It may therefore be predicted that analysis of a *representative* series of deaths from coronary heart-disease and of the occupations of the men dying (provided these have not been changed to any important extent on account of the disease) will show that

> Heavy workers have a smaller proportion of their coronary deaths in first clinical episodes of the disease, and a bigger proportion in later episodes, than light workers (Deduction A)

This deduction may be restated, that the ratio

$$\frac{\text{Deaths occurring in first clinical episodes}}{\text{Deaths occurring in later episodes}}$$

will be smaller among heavy workers than light workers It is, of course, an inference drawn from the more important part of the provisional hypothesis—that physical activity in work is associated with less severe coronary heart-disease

METHOD

We were much interested in the idea of testing the hypothesis in this way, but the only sample of death certificates available, though representative, was not really large enough for a thorough treatment of the method What follows must therefore be regarded as a trial run, a "pilot" of the proper test.

TABLE XI—NATURE OF WORK OF MEN (AGED 45–74 INCLUSIVE) DYING OF CORONARY HEART DISEASE, LONDON AND HOME COUNTIES, MARCH, 1952

Number of Deaths in Various Categories

<table>

</table>

The table includes all deaths registered in the sample period in London and the Home Counties (population approx. 11½ million) except for the following

In 4 deaths the men had no occupation, or the occupation was not stated on the certificate

In 3 deaths the occupation could not be graded.

In 21 deaths the certifying practitioner did not provide further clinical information.

The true total is therefore 184

Row 5 is made up of 19 ordinary certificates and 19 coroners' certificates

Statistical significance—The distribution of deaths in row 1—where we are most certain that the episodes were "first"—is significantly different (at the 5% level) from that of row 4 but the addition of row 2 makes the difference insignificant Tests of significance based on such small numbers lose most of their value, however, in the presence of a failure rate of 36% (we are dealing mainly with 118 deaths out of a possible total of 184) On the other hand of the 66 deaths not included in the 118, there were 59 (38 from row 5 plus the 21 cases about which the practitioners did not provide further clinical information) where occupation data were available 32 of these deaths were in "heavy' workers and 37 in 'light.' It can be shown that only a very bizarre distribution of these deaths to first or later episodes (of which there is no evidence) could falsify the general support given by these data to the hypothesis.

We have copies in our unit, as said, of a representative though small sample of death certificates (kindly supplied to us by the Registrar General for another and related study[1]). The sample included all deaths from cardiovascular (and some other) conditions that were registered during the first week of March, 1952, in London and the Home Counties and a one-in three sample of those registered in the second week. The certificates for Coronary Heart Disease, coded by the General Register Office to no 420 in the Sixth Revision of the *International List of Causes of Death,*[8] were extracted In nearly all cases the certifying practitioner had provided the unit with clinical information additional to that already on the certificate It was therefore possible to classify the deaths as follows,

ORDINARY DEATH CERTIFICATES

Deaths that, judging from the information which was provided by the patients' medical attendant seemed to have occurred in the *first* clinical episode of coronary heart disease

Deaths that seemed to have occurred in *later* episodes

"Unclassifiable" deaths

CORONERS' CERTIFICATES

Coroners' certificates, after necropsy without inquest, were classified into

Deaths that occurred in hospitals (the minority)

Deaths that occurred elsewhere—mainly at home (the majority).

The latter were regarded as deaths which more probably had occurred in first clinical attacks of the disease than in later attacks, though this can only be a guess, the former, since extraneous factors enter into the decision whether deaths in hospital are notified to the coroner or no, were allotted to "Unclassifiable"

This classification was done independently by two physicians, and only cases on which they agreed were allocated to "first" or "later" categories In the great majority of certificates there was no doubt about the appropriate categorisation, where there was doubt certificates were regarded as "unclassifiable"

We thus had the following groups of deaths

(1) Deaths in first clinical episode (ordinary certificates)
(2) Deaths in first clinical episode (coroners' certificates)
(3) The sum of these—all deaths regarded as having occurred in the first clinical episode of coronary heart-disease
(4) Deaths in later episodes (ordinary certificates).
(5) Deaths that could not be classified (ordinary and coroners' certificates)

Meanwhile, we also copied the occupation from each certificate and approached two more colleagues, specialists in industrial hygiene, with the request that they grade the various jobs in terms of the physical demands of the work, and, as in the previous test, we did not tell them our hypothesis. The new occupational grading used a 4-point scale heavy physical demands—moderately heavy—moderately light—light physical demands. The experts we consulted had each independently selected this scale, they separately agreed on the allocation of nearly all the jobs, in a few, so they informed us, they agreed after discussion, in three they were unable to suggest any grading (e)

RESULTS

Table XI presents the results of this classification of deaths and jobs, the horizontal rows corresponding to the categories of deaths listed above Row 1 gives the occupational distribution of the men whose death certificates were signed in the ordinary way, and which were judged to be deaths that had occurred in the *first* clinical episode of coronary heart disease on the basis of the special information supplied by the attending practitioner 2 of the 45 men who so died were heavy workers, and 20 were light workers Row 4 makes the same analysis for men considered to have died in *later* episodes, 5 of the 35 were heavy workers and 11 were light workers Reading down the *heavy* column it can be seen that of the 17 heavy workers who died of coronary heart disease, 2 on ordinary certificates were regarded as having died in their first attack, a further 5 were coroner's cases also classified as deaths in the first episode making 7 deaths during the first attack in

---

(e) Examples of the grading are

Heavy	*Moderately heavy*	*Moderately light*	*Light*
Builder's labourer Platelayer Agricultural worker	Bricklayer Sheetmetal worker Stoker	Tailor and cutter Maintenance engineer Medical practitioner	Clerk Compositor Telegraphist

XI(A)—DEATHS FROM CORONARY HEART DISEASE IN ' HEAVY ' AND ' LIGHT ' WORKERS

(Data of table XI)

NUMBER OF DEATHS

Episode of disease in which death occurred	All classes		Social class III		Social classes IV and V	
	First	Later	First	Later	First	Later
" Heavy "	13	11	1	4	11	7
" Light "	70	24	41	14	4	0

RATIOS

atios of deaths in first episodes to deaths in later episodes

	All classes		Social class III		Social classes IV and V	
	First	Later				
" Heavy "	1·2 :	1	0·25	1	1·6	1
" Light "	2·9	1	2·9	1	> 1·6	1

ers are taken from row 3—all deaths in first episode—and ow 4—deaths in later episodes—of table XI amalgamating he heavy and moderately heavy workers as " heavy " and he moderately light and light workers as " light."

ow 3 in the *heavy* column) The *light* column shows 34 of the 56 light workers were judged to have died eir first attack (20 on ordinary certificates and 14 oroners certificates) as against 11 in row 4 which considered to be deaths in later episodes. And so on able XI (A) orders the data of table XI in a form suitable testing the Deduction stated previously (f) The uction, on the whole, seems to be borne out Among " heavy " workers in all social classes combined ratio of deaths in first attacks to deaths in later cks is less than half what it is in the " light kers—13 to 11 or 1 2 1, compared with 70 to 24, or 1 If, as discussed in the Second Test, heavy kers have transferred in any numbers to light account of the disease and then died, it would mean t the number 24 is inflated and the ratio of 2 9 : 1 ong the ' light ' workers, compared with 1 2 : 1 in the eavy," underestimates the true difference in the ribution of deaths between these two groups

able XI(A) also breaks down the information by social s, and indicates why this has to be done In brief re is only one moderately heavy worker (a farmer) ong the 36 men in social classes I and II so it is not sible to test the deductions on our present data for e classes Social class III includes 5 moderately vy workers (engineering craftsmen) among the 60 s, but none of the really heavy workers Social ses IV and V, on the other hand, have all the really vy workers of table XI (they were mostly labourers various kinds) and only 4 light and moderately light rkers among the 22 deaths being considered. Since physical demands of work are thus strongly associated th social class, we had to try to make sure that under e of heaviness and lightness of work we were not merely dealing with an aspect of social class. The analysis of table XI(A) was therefore repeated *within* social class III, and *within* social classes IV and V taken together It can be seen that the deduction is also borne out within these classes so far as the numbers permit (fig 5)

The possibility that the trends of table XI are the product of social class factors is so interesting that we examined it in another way by making a similar analysis of the 67 deaths of married women from coronary heart-disease in the present sample of certificates. (The occupation given on the death certificate of a married woman is that of her husband.) The data referring to the married women showed *no* such trends as table XI(A) and Deduction A is refuted in them There was no evidence, that is to say that the *wives* of ' heavy workers in social classes III IV, and V had a different pattern of mortality from the *wives* of ' light ' workers. The nature of the physical demands of their jobs, it may therefore be proposed, affects the coronary experience of men as a direct *occupational* influence : if physical activity in work was only a reflection of *class* (or social economic) influences the natural history of the disease in their wives might well also have been affected (g)

Summing up this death certificate material which deals with current experience, thus also provides some support to the provisional hypothesis by bearing out deductions drawn from it Heavy workers there is some evidence, tend to have coronary heart-disease in a more benign and chronic form than light workers, and to die more commonly than light workers in second or later episodes of the disease. That is to say, using independent data, an association has been demonstrated or (at least there is promise of it when adequate numbers are available) between physical activity at work and the *course* of the established disease This association is complementary to that already demonstrated with incidence mode of first clinical presentation, initial severity of the disease, and early mortality rate.

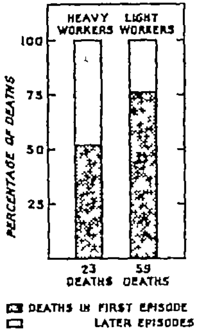

Fig. 5—Nature of work of men, aged 45–74 dying of coronary heart-disease in London and home counties in March, 1952.

III COMMENT

The present study began with observation of transport workers and the finding that one group of them the conductors whose job obviously involved considerable physical activity, had a different experience of coronary heart-disease from the drivers, whose job

---

) We had not intended to extend the present study beyond 65 years of age because the other parts of it are limited to middle age. But available numbers were too small especially when it became essential to break them down by social class. The tables therefore include the deaths occurring at 45–74 years of age For the same reason it was also necessary to amalgamate the moderately heavy workers with the heavy and the moderately light with the light ; and these groups will henceforth be termed " heavy " and " light " for short. Again, to ensure sufficient numbers, the cases of row 1 could not be considered separately from the coroners cases of row 2 so that in effect rows 3 and 4 can alone be used in testing the deductions. (As the distribution of deaths at 65–74 years is very similar to that at 45–64 years, the introduction of another decade does not introduce a new element into the discussion in so far as the present problem is concerned. The other amalgamations were equally undesirable but since they made the tests more rigorous —blurring the contrast between row 1 and row 4 for instance—we thought them justifiable.)

(g) Another deduction involves a slightly different treatment of the data It may be postulated that the *duration* of the disease before death, in a representative series of deaths will be longer in heavy workers than in light workers Using only the ordinary certificates with adequate information, such an analysis shows that the deduction is borne out. Of 16 heavy workers who died of coronary heart-disease aged 45–74 years 12 died at three months or more, and 4 died in less than three months, after the clinical onset of the disease. In 59 light workers the duration before death was three months or more in 25 men, and under three months in 34

(There were 57 deaths ascribed to myocardial diseases in men aged 45–74 years in the sample of death certificates. It has been suggested that these deaths should be amalgamated with those certified to coronary disease in analysis of cardiovascular mortality ; but scrutiny of the information now available to us indicates that such a procedure would be quite unwarranted.[4 11])

obviously involved less physical activity The conductors had a lower incidence of coronary heart disease More important, the disease they had was less severe, and was less often rapidly fatal. Analysis of the experience of postal workers and Civil Servants showed a similar trend when the postmen were compared with sedentary workers.

A provisional hypothesis was then made about the relations of physical activity in work to the incidence, severity, and mortality of coronary heart disease in middle aged men This hypothesis (briefly, that physical activity in work is associated with a more favourable experience of coronary heart disease) has now been tested in three different ways—on four independent bodies of evidence, on data from the same source as the original hypothesis and on other data remote from it, basing predictions on deductions and extensions from the hypothesis as well as on parts of the hypothesis itself

None of the tests we have applied (they are all reported in part II) falsify the hypothesis, some support it strongly, some weakly The protection against coronary heart disease associated with physical activity in work has now been demonstrated, in some measure, in national, regional, and group statistics, in the mortality of three social classes separately, and of the larger occupation groups in them individually, in the morbidity from coronary heart disease of several grades of workers, as well as in their mortality, over the range of middle age and within it, when the standard of diagnosis was held constant and was probably high, and when it may have varied widely, currently and twenty years ago, before the disease was commonly diagnosed and since, on two separate gradings of physical activity, and approaching the problem through the study of "populations" as well as by the collection of cases Reliance may be placed on the cumulative effect of the regularities that have been demonstrated, however inadequate some individual pieces of evidence by themselves so obviously are Moreover, the constancy of the association in such varying circumstances encourages the hope that we are dealing with a causal relationship—the most likely origin of such a constancy The hypothesis, therefore, may be regarded as a useful one which has so far survived Several questions that arise will now be briefly discussed

PHYSICAL AND PSYCHOLOGICAL FACTORS

The most important question is about the difficulties, in this type of study, of separating observations of the physical aspects of work from observations of other aspects such as the mental and socio economic In the present instance it is quite impossible to be sure how far we have succeeded in isolating physical activity from, for example, confounding psychological factors Special pains were taken to focus on this physical dimension of work physical activity and inactivity were identified and examined in a variety of situations, and in each of them they seemed to be important variables If in fact we have been studying only, or mainly, psychological factors operating under cover of the physical, the association of these psychological factors with physical activity must be extraordinarily close, so close that no matter how the data are analysed from the physical point of view, the unknown psychological factors turn up instead or as well It is possible that psychological variables, such as work satisfaction and frustration, the presence or absence of anxiety, emotional equilibrium, or personality integration, are correlated with physical activity at work, and they may be in part produced by it But it seems unlikely that the relation between such psychological aspects and physical activity can be close and regular enough to explain in psychological terms the association with coronary heart disease that was found (a) in such a variety of occupations, and (b) in such a diversity of psychological situations The problem, it must be remembered, is not merely one of coincidence or complementarity in any particular job, but of intimate functional association of emotional equilibrium, for example, with a general physical attribute of work—its physical activity Another consideration is important There are, of course, differences in the psychological strains involved in different jobs and in the emotional support they afford, and these may apply generally to the men working in them. However, compared with such general environmental factors, the relative importance of the immediate personal situation (and what it means to the individual) is so much greater in the psychological field than in the physical that an intimate functional association of the psychological with a general physical factor, such as activity, again seems unlikely At any rate, it has yet to be demonstrated Nevertheless, it is quite conceivable that at the biological level, physical activity in work performs a stabilising function (for example in channelling so called aggressive drives) and this may be important in highly civilised societies and, for all we know, may be particularly relevant to conditions such as coronary heart disease However applicable these considerations may or may not be, it seems reasonable to postulate that physical activity of work is a relevant factor in coronary heart-disease, whether or no there also are significant psychological aspects, and whether or no these are closely associated with physical activity

POSSIBLE EFFECT OF PHYSICAL ACTIVITY ON CORONARY CIRCULATION

The next matter of interest is the possible mechanism whereby physical activity could influence coronary heart disease if the relationship is causal One relevant observation at least has been made—that men engaged in more active work do not appear merely to have a lesser total incidence of the disease but also, within this feature *more* angina This is easy to understand—that with greater effort a symptom, angina, induced by effort is commoner, and the outdoor nature of much heavy work may also be contributory Is it possible that this is all that is happening, and that everything else in the coronary circulations of the contrasting occupational groups is equal? that with more physical activity there is more angina, and that this is sufficient (by acting as an early warning signal) to produce the other and beneficial phenomenon of a substantially lower mortality

It is unlikely from the evidence (and from general experience of coronary heart disease also) that this can be the whole story If physical activity in work is effective solely by evoking the symptom of angina, certain corollaries should follow—which do not. The total incidence of the disease should be *higher* in the more active men (whatever the partition of cases between fatal and non-fatal), and it should be appearing at earlier ages because their greater exertion will be inducing symptoms and making manifest in them coronary heart

---

(h) Rough and ready psychological classifications of most of the Registrar General's occupation groups of 1930-3 They were attempted by two psychologist colleagues They place little reliance on them, among other reasons because of the variety of jobs included in single occupation groups, and because of gaps in their own experience It is interesting, therefore, that in spite of these reservations some suggestive findings emerged In social classes III, IV, and V, taken together, occupation groups involving (a) "team work", (b) "little or moderate responsibility for things", and (c) "banging, bashing and cutting" (i e, expression of aggression in action upon materials or physical objects), had less mortality from coronary heart disease than their relevant contrast groups These differences are not accounted for simply by the heaviness/lightness of the occupation groups concerned disease which in sedentary workers will be quiescent and undetected. Neither in the transport workers nor in the postal workers, however is there any evidence of greater incidence among the physically more active Indeed the total incidence is somewhat lower in the conductors and postmen despite its probable inflation with the cases brought to light by greater exertion Nor is there any suggestion that the disease is appearing in the physically more active at younger ages

The proposition then that their different rate of symptom formation and manifestation (highly important influences of occupation on health), together with the consequences of these alone distinguish the physically more active group from the physically less active would appear to be an inadequate explanation of the present observations. We need, therefore to consider the possibility that physical activity acts upon the coronary circulation itself as well as influencing the demands made upon it that greater physical activity benefits the coronary circulation or lesser activity damages it or both. What mechanisms may be involved can only be guessed: whether for example there is protection (a greater ability to "cope" with thrombosis/occlusion) because of hypertrophy of arteries and small vessels with activity (an increased coronary capacity with the increased blood flow of exercise,) or contrariwise whether there is a greater liability to thrombosis or atheroma with inactivity

Satisfactory evidence is not available on the possible contribution of sunlight and outdoor life (the last of these, at least strongly associated with physically active work), or the sedentary posture (not easily separated from lightness of work) or the effects of particularly violent or sudden physical efforts which may introduce other and harmful factors[1, 9, 22] Nor are there any facts on the occupational distribution of influences that may mediate the final results—dietary habits, and obesity or hypertension for instance. Meanwhile as a first step in the investigation of possible mechanisms we hope to define the prevalence of advanced coronary atheroma in men who were engaged in different types of work, bringing together the necropsy material at the London Hospital[16] with the present hypothesis, though special studies will be needed of the architecture of the main and collateral coronary circulation and of the blood lipids.(i)

OTHER OCCUPATIONAL AND SOCIAL FACTORS

There seem to be occupational factors in coronary heart-disease other than the physical effort of the job During the present inquiries quite substantial differences in their experience of coronary heart-disease have been encountered between occupational groups where no question of a substantial difference in physical activity arises. The group of general practitioners studied, for example, appeared to have twice the incidence in 1947–50 of the other doctors.[13] (j) The nature of these other occupational factors is unknown A highly tentative attempt at psychological analysis of the occupational mortality data has already been mentioned. The other scraps of evidence which we have do not suggest that the problem is simply one of responsibility—the executive officers for instance, do not have a higher incidence or mortality than the clerks Nor does it appear that mental work as such is sufficient to transform the incidence: schoolmasters whose experience was observed in much the same way have the same rates as the intermediate group of postal workers, the postal and telegraph officers supervisors, and postmen higher grade In physical activity these four occupations are similar though scarcely in mental (The total incidence in the schoolmasters in 1949 at 35–59 years of age was 2 0—41 cases—with an early mortality of 0 8 in these postal grades taken together the figures were 2 0 and 0 9 respectively)

Osler[14] commented on the ' remarkable fact with which we are all familiar—that angina pectoris is an affection of the better classes, and not often seen except in private practice. Allbutt[1] disagreed, and of course the greater prevalence of aortic syphilis before the first world war has to be remembered in connection with such discussions The Occupational Mortality Supplement for 1930–32 recorded a considerable excess of coronary mortality in the men of social classes I and II and in the course of an interesting discussion suggested that sedentariness of work and nervous and dietary factors may be involved.[17, 19, 21] (The standard—and fashion—in diagnosis may also be important in these class differences) Differences in nutrition (so likely to be proved important in atheroma, the basis of the disease) may provide another link between the contrasting coronary experience of Western and undeveloped countries[4, 5] and between war time and normal prevalence[10]

We are thus seeking at least three sets of factors in this field

(1) Physical activity/inactivity

(2) Other occupational factors (possibly including psychological ones).

These may operate *within* the same social class as well as contributing to the differences *between* the social classes. In addition, however there may well be:

(3) Other social factors (possibly including nutritional ones)

also tending to produce differences between the social classes. There is every reason to suppose that various physical, psychological, and social factors operate together and it is quite possible that unfavourable factors cluster in certain occupational groups.

CONSTITUTIONAL FACTORS

No evidence is available from the present study on the rôle of constitutional influences, traditionally so important, and of increasing interest in chemical and physical terms[2] What we are really concerned with, in a disease that certainly has many "causes," is heredity *in* environment The bus-drivers, for instance, had been driving London buses twenty-three years on average before their first clinical attack of coronary heart-disease, the conductors had "conducted" for twenty seven (Many of the drivers had been conductors for a time before they became drivers, but there is no evidence as yet that their experience was different from that of the men who had been drivers from the start) There are many ways in which constitution and early experience may affect the incidence and natural history of disease For example, they may influence initial and later choice of job—and also be related to susceptibility to particular diseases Or, personalities of certain types, and men with certain physiques, may find what they want in light rather than heavy jobs—and develop the diseases associated with their type of personality and physique, as well as the diseases associated with light work It is premature, however, when so little is known about either constitutional or environmental factors, to attempt any assessment of the contribution of each kind of factor to the production of coronary disease The problem is similar to the psychological one in that choice of a physical *category* of work, not any particular job, would need to be highly correlated with constitutional factors which increase proneness to coronary heart disease

---

(i) An incidental finding may be mentioned here. Analysing the deaths from coronary heart-disease in married women for the purpose of the Third Test it was noticed that compared with the men, they had far more of their coronary mortality in episodes of the disease later than the first. Among the men there were 83 deaths that had occurred probably in first episodes, and 35 probably in later episodes—a ratio of 2 4 : 1 In the married women using the same methods and information the numbers were 35 and 32 respectively or a ratio of 1 1 : 1 As discussed previously there is a substantial difference in this ratio between male heavy workers (1 2 : 1) and "light workers (2 9 : 1)—though not among their wives. That is to say the ratio among all married women is the same as in male "heavy workers. There are several possible explanations for this phenomenon besides the obvious one

(j) This excess, it is interesting to notice, was *over-all*, in all three main modes of first presentation of the clinical disease in angina pectoris as well as in coronary thrombosis —myocardial infarction and 'immediate mortality Such a uniform excess is unlike the pattern of the occupational differences in the disease that is the main concern of the present paper It is possible therefore that a high incidence of angina in the presence of a low total incidence, as in the conductors, (or more generally the frequency of angina pectoris as first clinical manifestation relative to that of rapidly fatal coronary thrombosis) may be an indicator that the coronary experience of different occupational groups is being affected by differences in the physical activity of these groups. When this is happening—the hypothesis might be advanced—men in the physically more active group who have a low total incidence and mortality for which their physical activity is materially responsible will nevertheless have as a discriminant feature a high absolute incidence of angina (or high, at any rate relative to the incidence of immediate ' death.) There are many possibilities in industrial medicine for testing such a hypothesis.

* * *

Since we consider that we are dealing with what is still hypothesis rather than established fact—at most an association has been established rather than a causal connection—we do not propose now to discuss the social implications of the findings It can, however, be pointed out that they may be relevant to the suggestion that there has been a real increase of coronary heart-disease in recent years—i e, during a period in which heaviness and hours of work have declined, during the second Industrial Revolution with its new sources of power, its increasing specialisation and mechanisation, in a time of growth in the scale of enterprise, with increasing numbers of men engaged in management, administration, and the bureaucracy Thus observations such as now reported may indicate future possible approaches to the prevention of coronary heart disease, though at what stages in the natural history of the disease intervention will become possible is not apparent However important the constitutional factors may be in coronary disease there is mounting evidence of variation of its incidence with environment in time, place, and society Meanwhile, we need evidence as to whether physical activity *outside* work (this may well also have diminished in recent years) in exercise and games, for example, can compensate for lack of physical activity *in* work If exercise is taken up late in a chairborne life it may conceivably even be harmful

IV SUMMARY

This report continues the epidemiological study of coronary disease and deals particularly with the relations of physical activity and inactivity in work to coronary heart disease among middle aged men

Transport workers, postal workers, and Civil Service executive officers and clerks were observed during 1949–50 Bus conductors (on double decker vehicles) were found to have less coronary heart-disease than bus drivers, and postmen less than telephonists, executive officers, and clerks Moreover, what disease the conductors and postmen had was less severe

On the basis of these observations, the hypothesis was advanced that

> Men in physically active jobs have a lower incidence of coronary heart-disease in middle age than have men in physically inactive jobs More important, the disease is not so severe in physically active workers, tending to present first in them as angina pectoris and other relatively benign forms, and to have a smaller early case-fatality and a lower early mortality-rate.

This hypothesis was tested in three ways

The early mortality-rate of conductors and postmen in 1951–52 was again found to be lower than that of the drivers and telephonists Since this "early mortality" (i e, death in the first weeks of the first clinical attack) seems to be the greater part of the *total* coronary mortality in middle aged men, an analysis was made of the Registrar General's occupational mortality data for 1930–32, this showed that at 45–64 years of age heavy workers had half the mortality from coronary heart-disease of light workers Examination of a sample of death certificates of coronary heart disease in London and the Home Counties during March, 1952, suggested that heavy workers died less often than light workers in their first clinical attack, and tended more often than light workers to have the disease in chronic form

Reference is made to possible mechanisms whereby physical activity and inactivity might affect the process of coronary heart-disease

Other possible occupational and social class factors in coronary heart disease are considered At least three possible sets of factors in this field need to be investigated (1) physical activity/inactivity, (2) other occupational factors, including possible psychological factors, (3) factors in social class, including possible nutritional factors There may be a cluster of unfavourable factors among certain occupations, particularly in the upper social classes

We are grateful to a large number of people for helping us in this inquiry the many hundreds of practitioners and hospital staff who provided us with information, the General Register Office for the certificates in the Third Test and other information, Dr R S F Schilling, Nuffield Department of Occupational Health, University of Manchester, and Dr R Murray, H.M Medical Inspector of Factories, for the classification of occupation groups used in the Second Test, Dr P H Nash and Mr R J Sherwood of the Occupational Health Sub Unit, London School of Hygiene and Tropical Medicine, for the classification of jobs used in the Third Test, the National Union of Teachers, the Teachers' Provident Society, and Mr A J Eedle, and our medical and lay colleagues in the Treasury, in other branches of the Civil Service, in the Post Office, in London Transport Executive (particularly Mr F H Spratling, Mr F J Lloyd, and Dr L G Norman), and in the Social Medicine Research Unit (particularly Dr J L E Hoffman for reading the manuscript and helping to classify the deaths in the Third Test, Dr E M Backett, who also helped to classify these deaths, and Mr V B Kanter, who did the psychological ratings of the occupation groups with him, Mrs I R Murray and the secretarial and computing staff)

GAS-GANGRENE INFECTION IN AN OPERATING-THEATRE

SIMON SEVITT
M.D. M.Sc. Dubl., F.R.C.P.I., D.P.H.
CONSULTANT PATHOLOGIST, BIRMINGHAM ACCIDENT HOSPITAL

A YOUNG man sustained a closed fracture of the ankle. Next day an open operation was done, after which he developed gas-gangrene of the leg necessitating amputation. *Clostridium welchii* was isolated from the infected leg and from the floor, walls, and air of the operating-theatre suite.

Case record

On Jan. 10, 1953, a man, aged 20, fractured and dislocated his left ankle while playing football. That evening the ankle was manipulated to relieve pressure on the skin over the dorsum of the foot, and a plaster-of-paris cast padded with sterilised cotton wool was applied in the casualty theatre, which is on the ground floor.

Operation.—Next day he was operated on in theatre 1 of the main theatre suite (see figure). The skin of the ankle was incised, a large butterfly fragment of the fibula was wired, the torn joint capsule and ligaments were repaired with Mersaline sutures, and the lateral malleolus was screwed. Penicillin powder was dusted into the wound, which was closed in layers with catgut. Finally a below-knee plaster-of-paris cast padded with sterilised wool was applied. A course of prophylactic penicillin 250,000 units six-hourly was started.

Progress.—Next day, Jan. 12, the patient's temperature was 101.2°F in the morning and rose to 104.6°F in the evening. At 2.30 A.M. on Jan. 13 the operation site appeared normal. Nevertheless polyvalent anti-gas-gangrene serum 25,000 units was given intramuscularly. Later that day the patient's leucocyte-count was 23,800 per c.mm. (polymorphs 90%). A course of aureomycin 1 g. daily divided in four doses was started. On the morning of Jan. 14 pus and gas bubbles were found in the wound, and microscopy of the exudate showed many large non-sporing gram-positive bacilli and some pus cells. Culture later gave a heavy growth of *Cl. welchii* and micrococci. At midday the wound was explored under general anæsthesia. Some foul pus was present, and the peroneal muscles were pale, gelatinous, and necrotic; these were mostly excised. Portions of muscle and of catgut and mersaline sutures removed from the leg gave a heavy growth of *Cl. welchii* and micrococci. Histological examination showed a gas-producing myositis. A course of blood transfusions was started, and eight pints of blood was given during the next two days. In spite of increasing the dosage of penicillin to 1,000,000 units daily and that of aureomycin to 2 g. daily, and giving 75,000 units of polyvalent anti-gas-gangrene serum intravenously, muscle necrosis extended, and the limb was amputated above the knee on Jan. 16. Within forty-eight hours the patient's general condition improved and the pyrexia was settling. Chemotherapy was discontinued on Jan. 21, and the patient was discharged to outpatient care on Feb. 14.

Possible Sources of Infection

Since the original fracture was closed, the leg muscles are unlikely to have been contaminated by *Cl. welchii* before the operation on the ankle. However, the skin may have been contaminated with *Cl. welchii* before the operation—e.g., on the football field—and the surgical wound may have been infected from the surrounding skin. On the other hand, *Cl. welchii* may have been introduced into the wound during the operation from sources not related to the patient. Attention was focused on this possibility because the ankle was operated on in a theatre the ventilation system of which had formerly disseminated tetanus and other anaerobic spores throughout the theatre suite (Sevitt 1949).

Operating theatre

The suite (see figure) is situated on the top floor of a four-storeyed building and consists of a main corridor, two operating theatres (theatres 1 and 2), each with an anæsthetising and sterilising annexe, communicating through a central assembling room, and other rooms. The ventilation is of the exhaust type and is produced by two power-driven fans, one for each theatre. The two air outlets are situated on an outside wall, and each communicates with an independent system of air ducts and vents. Air is drawn directly from each theatre, from each sterilising and anæsthetising room, and from the assembling room into the outside air.

Strong currents of air are produced and are largely directed into the two operating theatres from the main corridor. Air is drawn into this corridor up the lift shafts and stairway. The result is that air and dust from the main corridor of the theatre and from other parts of the hospital are drawn into theatres 1 and 2 while the ventilation is on.

Moreover, since the air vents are raised about 10 ft. above the floor, upward currents of air from the floor develop within each theatre and its annexes.

Bacteriological Investigation

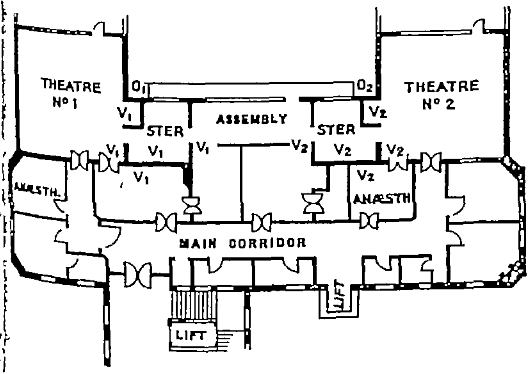
It was sought to answer the following questions:

(1) Was the dust of the floors, walls, and air of theatre 1 contaminated with *Cl. welchii*? If it was, how was this organism spread within the theatre suite, and how widely? Was the source within the theatre? This was asked because parts of the theatre walls were crumbling, and it was known that some of this wall plaster was bound by animal hair which contained various clostridia (Sevitt 1949).

(2) Were any of the operating materials used during the ankle operation, such as glove talcum powder, catgut or other suture material, plaster bandages, padding cotton wool, &c., contaminated with *Cl. welchii*?

Twenty-five swabs and portions of exposed wall plaster from different areas of the floors and walls of theatres 1 and 2, from the top of the operating lamp in theatre 1, from the walls of the assembling room and from the floor of the main corridor of the theatre suite were examined (see table).

The air of theatre 1 was sampled by Dr E. J. L. Lowbury on Feb. 28 during a surgical operation and with the ventilation working. A slit sampler was used, and narrow streams of air were sucked on to revolving discs of soft moist agar. These were broken up, and the pieces were inoculated into six flasks of cooked-meat broth.



Plan of main theatre-suite.

O_1, O_2 = fan-driven exhaust outlets of the ventilation units.
V_1, V_2 = air vents at various points in theatres and annexes.

BACTERIOLOGY OF DUST AND AIR OF MAIN THEATRE SUITE

Source and nature of specimen (no examined)		Date of collection	Bacteria present	
			Cl welchii	Other organisms
Theatre 1	Floor swabs (2)	Jan. 16, 1953	Both +	*Cl sporogenes*, A.S B, *Staph albus*, microco and coliform bacilli
	Swab from top of operating-theatre lamp (1)	,,	+	Proteus, micrococci, and A.S.B.
	Exposed wall plaster (5)	,,	2 + 3 −	A S B and micrococci
	Wall swabs (3)	March 6, 1953	−	Micrococci or A.S B. or both
	Air samples (8)	Feb 28, 1953	+	Coliform A.S B, micrococci, and other c tridia
Theatre 2	Floor swabs (2)	Jan 16, 1953	Both +	Hæmolytic strep A.S.B, and micrococci
	Exposed wall plaster (4)	,,	−	Micrococci and A.S B
	Wall swabs (4)	March 6, 1953	1 + 3 −	A.S.B or micrococci
Assembling room	Wall swabs (2)	,,	Both +	Micrococci and A.S.B
Main corridor	Floor swabs (2)	,,	Both +	Micrococci and A.S B

A S B, aerobic sporing bacilli

Seventeen specimens of plaster from the walls of theatres 1 and 2 and four from the walls of the assembling-room were removed with a sterile drill, and each was cultured in duplicate

The reels of twenty six catgut ampoules from 23 different batches (including those used at the operation), specimens from six reels of mersaline sutures, including those used at the operation, and four of 'Nylon' sutures from theatre 1 were cultured after washing to remove the immersing alcohol

Also cultured were samples of autoclaved talcum (glove) powder, penicillin powder spray, 'Benzomastic' skin paint, skin marking ink, all similar to, or identical with, those used during the operation, duplicate strips (3 × 2 in) from the inside of four plaster-of paris ('Cellona') bandages, two from the main theatre suite, and two from the casualty-theatre, and samples of autoclaved and unsterile cotton-wool both from the casualty-theatre and from the main theatre suite

Methods

The various swabs and specimens, &c, were inoculated into Robertson's cooked meat broth, when possible in duplicate, and these were incubated at 37°C The cultures were examined after 2 and 7 days' incubation and, if necessary, one and two weeks later Gram stained films were prepared, and subcultures were made on to horse blood agar plates Sometimes the broth was heated to destroy non sporers before subculturing

Identification of *Cl welchii* was based on its morphology, including the virtual absence of spores, its colonial appearance, its failure to digest the meat in cooked meat broth and the absence of other proteolytic properties except for the liquefaction of gelatin, the ability to produce acid and gas from iron peptone water media containing glucose, maltose, lactose, and saccharose and failure to ferment mannitol, the ability to precipitate a lipoprotein from human serum and the inhibition of this property by anti welchii anti toxin (the Nägler reaction), the "stormy fermentation" of milk, &c

Other bacteria were isolated and identified by the usual methods Virulence tests of clostridia were made in mice

Results

The results of the cultures from the floor, walls, and air of the theatre suite are summarised in the accompanying table

Cl welchii in the Theatre

This organism was isolated from all the swabs of the floors of theatre 1, theatre 2, and the main corridor, from the top of the operating-lamp in theatre 1, from all the cultures of the air of theatre 1, from the surfaces of the walls in the assembling-room, from some of the exposed wall plaster in theatre 1, and from the surface of one of the walls in theatre 2

Other organisms included aerobic sporing bacilli of the *Bacillus subtilis* group, various micrococci, coliform bacilli, proteus, diphtheroids, *Cl. sporogenes* and other clostridia, and a hæmolytic streptococcus.

Theatre wall plaster—Only two of the first five plaster specimens from theatre 1 and none of the four from theatre 2 yielded *Cl welchii* Since these were taken from pl crumbling on the surface and exposed to the air, the inc sistent results could have been due to irregular contaminat of the walls with air borne dust carrying *Cl welchii* spo Therefore the wall plaster was re-examined Specimens drilled out from areas where the wall paint was intact, flaming and scraping it off Four specimens each from thea 1 and 2 and the assembling room were examined, but n grew *Cl welchii* or other anaerobic bacteria, eight remai sterile It was concluded that the wall plaster was not a sou of *Cl welchii*

Cotton-wool—The unsterilised coarse brownish cotton received from the casualty and main operating thea yielded *Cl sporogenes*, a non toxigenic strain of *Cl te* another non pathogenic clostridium, and various saproph aerobes, but *Cl welchii* was not found. This kind of cott wool is commonly used to pad plaster of paris casts over clo fractures Interesting as these findings are, they are proba irrelevant to the present investigation, because the cott wool used under the plaster casts of the present patient autoclaved white cotton-wool

Plaster-of paris bandages grew only an aerobic long slen gram positive bacillus, probably a sporer

The various specimens of *catgut*, *mersaline* and *nylon sutu* *talc powder*, *penicillin powder*, *benzomastic paint*, and *marking ink* were sterile except for cocci or diphther contaminating the mersaline and nylon reels

Efficiency of theatre autoclaves—Tests had last been d four weeks before the operation and were then satisfacto Tests made a few days after the operation showed that au claving at 20 lb for 20 minutes (dressings) and at 15 lb. 15 minutes (gloves) killed the test *B subtilis* spores

Discussion

The investigation of the source and route of infecti with bacteria like *Cl welchii*, which cannot yet divided into different phage or serological types, is fraug with difficulty Direct proof is virtually impossible wh the event is over, and a judgment can only be based indirect and circumstantial evidence Such was the sit in the present investigation

Since *Cl welchii* was isolated from the gas gangren muscle of the patient it is considered to be the bacte cause of the infection *Cl welchii* was also present only in the air and dust of theatre 1, where the an was operated on, but also was widely distributed in dust throughout the main theatre suite Specimens talc powder, suture material, &c, similar to, or identi with, those introduced into or near the patient's wou did not contain *Cl welchii*

It is therefore reasonable to conclude that the air theatre 1 contained welchii spores during the operat on Jan 11, and that aerial contamination of the patien ankle took place then

Similar contamination of surgical wounds at oth times must have happened Nevertheless, postoperat gas gangrene is very uncommon This is because co tamination is not infection For gas gangrene to devel more than the right bacteria are required, mus ischæmia or necrosis or sepsis or other factors are nec ry In the present patient ischæmia of the peroneal muscles due to arterial spasm may have been present nd have provided the necessary tissue conditions for the *evelopment of gas gangrene.*

xhaust Ventilation

The real villain of the piece is the exhaust type of entilation which sucks air and dust from the hospital nd theatre corridors and from other parts of the hospital nto the operating theatres In other words, each theatre ecomes an "air sewer" draining much of the hospital ir and dust and, since dust commonly bears spores of l. *welchii*, the theatre suite is widely contaminated with his organism. Other ways of spreading *Cl welchii* may ave occurred, such as the contamination of the theatre orridor floor by dirt from the soles of shoes.

Further, upward draughts towards the vents suck loor dust into the air Every wound made or exposed in he theatre is therefore exposed to floor-dust bacteria ncluding *Cl. welchii*. Moreover wounds have been nfected with other bacteria, such as the two cases of etanus which were traced to aerial dissemination of etanus spores by the same ventilation plant (Sevitt 1949).

Air Hygiene for Operating theatres

Exhaust ventilation was originally introduced into operating theatres to remove steam from the sterilisers and to make the theatre comfortable for the surgeon and the theatre staff to work in Though this is a highly admirable purpose, the problem of designing ventilation to minimise wound infection as well as to ventilate the theatre was not considered until recently Bourdillon and Colebrook (1946) introduced an air-conditioned room for the dressing of burns. Filtered warmed, and humidified air is passed into this dressing room from the ceiling by a forced ventilation plant and is extracted at floor level. This ensures "an atmosphere almost free from bacteria at the start of the dressing and a rapid evacuation of organisms disseminated through the air in the course of each dressing"

The incidence of added infection due to hæmolytic streptococci, *Pseudomonas pyocyanea*, and proteus among the burnt patients was greatly reduced after the introduction of this dressing station (Colebrook et al 1947, 1948). A controlled trial now in progress has already confirmed the reduction of added infection with *Ps pyocyanea* and other coliform bacilli when the burns are dressed in cleansed air (E J L Lowbury, personal communication)

If ventilation systems designed to control the hygiene of the air within operating theatres were introduced it is highly probable that the incidence of surgical wound infection would decline. In particular, aerial dissemination of tetanus and *Cl. welchii* spores, such as gave rise to the previous and present investigations, would not occur

Surgeons and hospital authorities who insist on sterile gloves and instruments for operations should be equally particular about the cleanliness of the air in their theatres. Clean air is desirable in all theatres but is of high priority in those dealing with traumatic, thoracic orthopædic and neurosurgical cases, in all of which the hazards or results of infection are particularly serious.

Summary

An open operation was done on a closed fracture of the ankle. Gas gangrene followed, and the leg had to be amputated: *Cl. welchii* was isolated from the infected muscle.

An investigation showed that the floor, walls, and air of the operating theatre were contaminated with this organism It was known that the exhaust ventilation of the theatre suite sucked air and dust from much of the hospital into the operating theatre and disseminated this dust within the theatre. It was therefore concluded that aerial contamination of the wound took place during the operation and that this was brought about by the air currents produced by the ventilation

Thanks are due to Mr W Gissane clinical director, and to Mr K Barnes, for the use of their patient's notes to Dr E J L Lowbury for the air sampling and to Mr J Skelding F.I.M.L.T for skilled technical assistance The writer is in part time employment by the Medical Research Council

CORTISONE AND RHEUMATOID DISEASE

H F West
M.D Lond. M R.C P D T.M
CONSULTING PHYSICIAN

G R Newns
M B Birm M.R.C.P
SENIOR REGISTRAR

SHEFFIELD CENTRE FOR THE INVESTIGATION AND TREATMENT OF RHEUMATIC DISEASES

Many papers have been written during the last four years on the use of cortisone in the treatment of rheumatoid disease The profound effect of this hormone especially in a daily dosage of 100 mg or more, on the symptoms and signs of the disease in the early weeks of treatment is acknowledged by all Unfortunately doses bigger than 75 mg a day can rarely be maintained for many months without serious complications. It has yet to be shown whether a restricted dosage of 50–75 mg a day is worth while Many favourable opinions have been expressed but they have not been backed by the kind of evidence that one expects from the clinical trial of a new treatment (see Tenth Rheumatism Review 1953)

The present study was made to provide a definite answer to the question whether the oral administration of cortisone acetate 50–75 mg a day continued for a long time, favourably affects the course of rheumatoid disease or not

The Treated Group

31 patients with rheumatoid disease were started on long term cortisone treatment from one to three years ago 1 fell out after three months, 3 died after a year's treatment, and the remaining 27 (table I) are still receiving cortisone to date The progress of the 27 patients will be considered first. The average duration of daily cortisone *acetate therapy for this group is nineteen months.*

At the beginning of treatment each patient had many joints affected (clinically and radiologically), the disease was active, and the erythrocyte-sedimentation rate (E.S.R.) was above 15 mm in 1 hr (Wintrobe) According to the classification of Steinbrocker et al. (1949) 16 patients were in stage II and 11 in stage III.

TREATMENT

In the early months of the investigation cortisone acetate was given by intramuscular injection For the last two and a half years it has been given solely by mouth The dose given during the last two years has fluctuated between 50 and 75 mg a day, occasionally

TABLE I—DESCRIPTION OF PATIENTS

—	No	Age range (yr)	Average age (yr)	Range of duration of disease (yr)	Average duration (yr)
Men	12	35–60	46	2–33	7
Women	15	18–51	41	1½–16	5½

exceeding 75 mg for a week or two when the symptoms and signs have been most acute In addition each patient has been given physiotherapy, mainly active Only 1 patient has been able to dispense with aspirin or compound codeine tablets for more than a few months The average patient has needed at least eight tablets a day for most of the time It would not have been possible to stop these patients from resorting to aspirin

RESULTS

To assess progress the patients have been seen at least every four weeks for interrogation, for physical examination of joints, grip, weight, blood-pressure, &c , and for laboratory investigations—E S R , hæmoglobin packed-cell volume, eosinophil-count, and plasma protein, plasma fibrinogen, and plasma cholesterol levels

A sound idea of the results of treatment in rheumatoid disease may be gained by answering the six questions below In assessing the results for any treatment for rheumatoid disease it is essential to make as much allowance as possible for the natural fluctuations in the activity of the disease It is so natural to select patients for a new treatment at the height of an exacerbation and to be misled into believing that the improvement, which would have come about naturally in many cases, has been due to the treatment Consequently the clinical assessments given below are those for the six months before treatment began and for the last three months of treatment The laboratory data represent the average of readings during the same periods

(1) *Have the affected joints ceased to stiffen with rest?*

96% of the patients still have joints that stiffen with rest The intensity of the stiffness in an affected joint and its duration after a night's rest provide in most cases of rheumatoid disease the simplest means of assessing the activity of the disease

(2) *Are analgesics still necessary to relieve pain and stiffness?*

89% still find analgesics necessary to obtain relief from pain and stiffness Aspirin is the best friend of the rheumatoid patient When a patient says that she cannot manage without aspirin, this is almost invariably a true symptom of continuing activity of the disease

(3) *Can the patients do more?*

As a group they have been able to do more in recent months than in the six months before treatment, but the increase is small The meanings of the numbers P1–P5 in the tables are as follows

P1 able to work and play as a normal person of the same age

P2 able to do light work without real difficulty but unable to manage heavy work or vigorous games because of the rheumatoid disease

P3 able to do light work only with considerable difficulty , taking some hours to limber up each day , poor grip and considerable limitation in walking and on stairs

P4 only able to struggle round indoors with aids , needing help to dress and to get up and down

P5 bed fast , unable to stand or to attend to simple needs

Patients often fluctuate between grades P2 and P3 in a few months When this has been the case during a period of assessment (table II), they have been graded as P$2^1/_2$ In no case has the reduced physical ability been due mainly to burnt out rheumatoid arthritis

(4) *Has the E S R fallen?*

The average E S R before treatment was 34 mm in 1 hr (Wintrobe) The average E S R during the last three months of treatment was 29 mm in 1 hr (Wintrob Only 2 patients have had an average E S R. below 15 m in 1 hr during the last three months

TABLE II—ASSESSMENT OF RESULTS

Physical ability (P grades)	Improved by			No change, at		Worse by
	2	1	$^1/_2$	P3	P$2^1/_2$	$^1/_2$
No of patients	1	5	8	6	5	2

(5) *Has the anæmia, the raised plasma fibrinogen level, a abnormal albumin-globulin ratio associated w rheumatoid disease been corrected?*

The average Hb before treatment was 11 3 g per 1 ml , and in the last three months of treatment 12 3 per 100 ml The average plasma-fibrinogen level bef treatment was 0 42 g per 100 ml , and in the last th months of treatment 0 34 g per 100 ml The aver albumin-globulin ratio was 1 6 1 both before treatme and in the last three months of treatment

(6) *Do radiographs of affected joints taken at the beginn of treatment and recently show evidence of at least arrest in the disease?*

There was new or increased bone erosion in 16 (60% no change or absence of bone erosion in 8 (30%) , hea bone erosion in 1 , and doubtful erosion or not kno in 2 It was impossible to make a scientific assessmen changes in bone density Our opinion is that in onl cases had bone density definitely improved In 1 of th patients fresh erosions had developed in other bon Where there was reasonable doubt about the appeara of new erosions or the extension of pre existing erosio the result was recorded as " no change "

According to Steinbrocker's criteria of improvement patient is in complete remission, 4 patients show mark improvement, 4 show minor improvement, and 19 unchanged

Controls

The impression gained from many published studies differing methods of treating rheumatoid arthritis that at least 15% of patients recover and at least 5 are much improved The results given above appea to fall so far short of this standard that it was conside very necessary to assess by the same criteria a sim group of patients who had not received cortisone

From about 1000 cases seen in recent years 27 w selected to pair with individual cases in the cortiso treated group The patients naturally had to be of same sex and under our observation during the sa time They were selected as most nearly resembling th cortisone treated opposite numbers as regards age, du tion of disease, and distribution of affected joints for instance, a given cortisone-treated patient, aged had had the disease for four and a half years, and h the joints of all four limbs involved, then a control w selected who most closely resembled him in th particulars

Comparisons

(1) *Joints stiffening with rest*

Cortisone group 96%
Paired group 89%

(2) *Need for analgesics*

Cortisone group 89%
Paired group 93%

(3) *Physical ability*

Cortisone group before, P3 , recent, P2 7
Paired group before, P2 6 , recent, P2 3

(4) *E S R (Wintrobe)*

Cortisone group before, 34 mm. , recent, 29 mm
Paired group before, 23 mm , recent, 25 mm.

(5) *Hæmoglobin*

Cortisone group before, 11 3 g , recent, 12 3 g
Paired group before, 13 5 g , recent, 13 2 g (M.R method

The hæmoglobin estimations for the cortisone treat patients were made by an oxyhæmoglobin method w a standard checked by gas analysis experiments. T M R C method is generally known to give high readi —about 8% above those given by the other method is concluded that the hæmoglobin values today in bo groups are about the same, and that in neither group have they risen to average normal levels Plasma protein and plasma fibrinogen levels were not estimated as a routine in the paired patients

(6) *X ray changes*

Of the 27 controls only 20 had suitable films taken at the appropriate times. Of 20 pairs there was an advance in erosions in 15 of the cortisone group and 12 of the controls.

(7) *Strength of grip*

One expects men to be able to send the mercury up to the top of the sphygmomanometer scale (260 mm.) and women to at least 200 mm The results were as follows

Cortisone group : latest reading right 135 mm. left 153 mm.
Paired group latest reading, right 122 mm. left 116 mm.

The interpretation of this difference is complicated by the fact that the paired group had their readings taken in the morning, whereas most of the cortisone treated group had their reading taken in the afternoon The physical abilities of most patients with active rheumatoid disease improve as the day wears on and are usually maximal by mid-afternoon

Well-being

Much has been said of the increased well being that cortisone treatment imparts to rheumatoid patients. This is undoubtedly the case in the early weeks of treatment, but it falls off in time. Whether any remains after a year's treatment is difficult to assess. No attempt has been made to assess and compare the sense of well-being in the paired group

DISCUSSION

The evidence so far presented shows that the administration of cortisone acetate, as described above does not have a favourable effect on the course of rheumatoid disease. It may well be asked why it is that in spite of continuing disease activity in both groups the average physical ability of the patients improved. The answer is that in a unit devoted almost entirely to the investigation and treatment of rheumatoid disease vigorous measures are taken to restore muscle power so far as is possible, and to retain it also to prevent and to correct deformities. But for these measures some patients would have sunk to category P4.

Complications

Infections mental and endocrine disorders operations—No abnormalities as regards infections and inflammations, mental behaviour or the endocrine system have been noted during a prolonged treatment with oral cortisone acetate in the restricted dosage The X ray appearances of the lungs have remained unaltered. Three major and some minor operations have been done without untoward happening For these operations the dose remained unaltered—it might have been wiser to raise it temporarily (see theoretical discussion below)

Gastric hæmorrhage—There have been five instances in 3 patients. No hæmorrhage occurred in the controls The bleeding occurred in spite of precautionary advice on diet and the use of antacids.

Osteoporosis—No evidence of a general increase in bone porosis has been noted but 1 patient a man aged [illegible] with long-standing disease, had a pathological fracture of the neck of the femur An acrylic prosthesis has remained satisfactory to date (eight months) Only 1 patient had open epiphyses they closed normally

Weight increase—The average weight before treatment was 59 kg. and in the last three months of treatment [illegible] kg. Of the paired patients only 22 had weight records at about the same intervals Of the 22 pairs the average weight of the cortisone-treated patients before treatment was 60 kg. and in the last 3 months of treatment 66 kg whereas of the controls it was 61 4 kg before treatment and 6[illegible] 7 kg in the last three months of treatment. The difference in increase is 4 7 kg (10 lb) This increase in weight has not bothered the men but some of the women do not appreciate what they consider to be a disproportionate increase about the hips Many have faces fuller than normal. The weight increase is mentioned under complications since it is of abnormal distribution and not related to a subsidence of disease activity

Enlargement of heart—When the chest films were being examined for evidence of tuberculosis, it was noted that in many cases the heart appeared to have increased in size On close examination it was found that of the most recent films 17 showed a raised diaphragm, 4 a lowered diaphragm and 6 no change The films were referred to Dr T Lodge for an opinion about alteration in heart size He gave his opinion that 6 showed definite enlargement These 6 comprised the 4 with the lower diaphragm, 1 with an unaltered diaphragm level and only 1 of the 17 with a raised diaphragm level. One wonders how many more would have been considered enlarged had there been no raised diaphragm to complicate the assessment It seems most likely that increase in fat in the omentum and in the abdominal wall accounted for the elevation of the diaphragm

Blood pressure—The average blood pressure before treatment was 131/79 mm Hg and the average of the last two readings 135/84 mm Hg Unfortunately too few of the paired patients had blood pressure readings at the appropriate times to allow a comparison One can at least infer that for the group as a whole there was no gross increase in blood pressure

Serum-cholesterol level—The average total serum cholesterol level before treatment was 143 mg. per 100 ml, and in the last three months of treatment 160 mg per 100 ml. In only 1 patient did the total serum-cholesterol level exceed 200 mg per 100 ml.

Leucocytosis—At the start of cortisone treatment there is usually a considerable leucocytosis In this study the average rise was from 7700 to 11 400 per c mm The average of the last (most recent) two readings for the group was 9200 per c mm The average counts for the paired group were 8100 per c mm at the beginning and 7300 per c mm at the end In considering whether the treatment given has been physiological or not this rise in the total white-cell count must be considered. The lymphocyte-count appeared to remain stable More than eight hundred eosinophil-counts were made during the study In only 1 patient did the counts remain below 50 per c mm. ; in 6 they remained less than 100 per c mm., and in 9 they exceeded 200 per c mm

Withdrawal syndromes—Relative adrenocortical deficiency and acute deficiency at times of stress may follow the withdrawal of cortisone acetate after prolonged therapy Such states were not observed in this study but must be considered when evidence for and against this therapy is weighed. Now that a comparatively simple laboratory assay of the adrenals output of hydrocortisone is available (Norymberski et al 1953 Brooks and Norymberski 1953 West 1953) it is not difficult to find out whether the adrenal function has been restored, and whether a normal response follows the administration of corticotrophin This still does not tell us whether the pituitary has been restored to normal activity and whether it can respond to severe stress Little is known of the stresses in man that call for a rapid increase in adrenocortical activity, but it is known that the stress of a major operation may call for the secretion of 100 mg or more of hydrocortisone in twenty four hours

Fatalities

The first 2 deaths have been fully reported (West and Newns 1952) Both patients had received cortisone daily for about a year One died of amyloid disease, and the other died suddenly after having been without cortisone for four days In neither case could death be ascribed to cortisone therapy, but in both cases death was undoubtedly hastened by its use

The third patient, a man aged 36, developed polyarteritis nodosa He was a typical case of rheumatoid disease, the signs having appeared first in the proximal interphalangeal joints two years before cortisone therapy was begun The first symptoms suggesting polyarteritis appeared in the fourth month of treatment The dose of cortisone was increased, but he died five months later as a result of hæmorrhage from one of many gross intestinal arterial lesions Lesions developed with a prolific cellular exudate while he was receiving cortisone acetate 150 mg a day This single case might not be considered remarkable but for the occurrence of similar cases in the U S.A Levin et al (1953) reported 3 such cases in their series, and we have heard indirectly of several others in the U S A. The cortisone treatment must be held at least partly responsible until more evidence is available

Theoretical Considerations

Is there any theoretical reason why cortisone should have a curative effect in rheumatoid disease ? There is not No abnormality in corticosteroid metabolism has been confirmed in this disease This does not exclude the existence of an abnormality, since comparatively little is yet known of the metabolism of corticosteroids or of the essential rôle they play in the tissues, or of the tissues' needs We have now estimated the total urinary output of the known metabolites of cortisone and hydrocortisone (as 17 ketogenic corticosteroids) of 30 rheumatoid patients, and have found their output on the average about 40% below that of normal controls When these levels are raised to those of normals, however, the disease does not appear to be significantly affected The levels can be raised by the administration of either corticotrophin or cortisone acetate

Are there theoretical reasons for condemning the administration of cortisone acetate (in the doses used above) for a long time ? It may be held that a hormone is being administered in unphysiological amounts, regardless of the diurnal variation of the body's needs and regardless of the need for considerable variations during certain stressful episodes The doses given correspond to less than the natural output during the stress of a major operation, but they correspond to twice the normal day-to day secretion Evidence of the unphysiological nature of these doses may be seen in the patient's increase in weight and possibly in the raised total white-cell count

Some evidence has been provided in our laboratories that cortisone acetate 50 mg administered daily will completely suppress the endogenous output of hydrocortisone-like steroids (Norymberski et al 1953) Does this matter ? So far we have no evidence that it does What does matter is the consequence of stopping cortisone therapy after the adrenal production of hydrocortisone has been suppressed for a long time

Conclusions

Cortisone acetate given for a long time in doses of 50–75 mg a day does not favourably influence the course of rheumatoid disease It does not necessarily follow that prolonged administration is not of benefit in certain types of rheumatoid disease Claims for such benefit have not yet been substantiated by controlled studies

In attempting to justify the prolonged use of cortisone acetate, the early benefit enjoyed by some patients and the possibility of some continuing improvement in well-being must be weighed against complications that cannot necessarily be foreseen or prevented Until such complications can be avoided with certainty the long-term stration of cortisone acetate for rheumatoid cannot be recommended

Does this mark the end of a chapter ? We do not think so for two reasons

(1) A dose of 50 mg of cortisone acetate produces a profound effect in some cases of rheumatoid disease, particularly in some long standing cases Now such a dose has not been shown to relieve any other kind of inflammation. The fact that these good effects are not maintained suggests that some adaptation takes place to the raised level of circulating corticosteroid Preliminary studies have not shown any alteration in the total excretion of cortisone metabolites following prolonged therapy (unpublished data), but the possibility remains that an alteration in the metabolism of cortisone does take place which, when understood, may help us to overcome the loss of therapeutic effect

(2) Far too little is known of the metabolism of corticosteroids to exclude them from an important rôle in rheumatoid disease or in hypertensive diseases or in some forms of cancer.

Summary

Cortisone acetate 50–75 mg daily has been administered to 27 patients with rheumatoid arthritis for an average of nineteen months A further 3 patients treated in this way died after nine to thirteen months

A comparison has been made with a similar group of 27 patients who did not receive cortisone

The conclusion has been reached that long-continued cortisone therapy for rheumatoid disease is not to be recommended

The observations recorded are not thought to exclude corticosteroids from a rôle in the pathogenesis of rheumatoid disease

Most of the cortisone acetate used in this study was provided by the Medical Research Council and Nuffield Foundation joint committee on cortisone and A C T H in chronic rheumatic diseases, to whom our thanks are due Particular thanks are due also to both the patients and the nurses for their loyal coöperation

A SKIN TEST FOR MUMPS
USING CEREBROSPINAL FLUID FROM CASES OF MUMPS MENINGITIS

CHILDREN'S CLINIC, ATHENS UNIVERSITY

During the last epidemic of mumps in Athens we often observed cases with involvement of the central nervous system 107 patients presenting symptoms of meningitis were treated in our clinic

Montenovesi (1952), reporting an outbreak of epidemic parotitis in Verona in 1951, mentions 54 cases of meningitis He cites Fox and Grotts (1949), who described 23 cases of meningitis among 35,322 patients with mumps, of Hack (1910), who found 9 cases among 476 patients, of Gott (1950), who found 10 cases among 3306 patients, and of Cozza and Capretti (1948), who found 27 among 55 patients

The meningo encephalitic symptoms, which appear occasionally before or without involvement of the parotid glands, are not only of practical diagnostic importance but be of theoretical interest. It is now well established hat the meningo-encephalitic symptoms are due to nfiltration of the virus into the central nervous system

The virus has been isolated from the cerebrospinal fluid c.s.f) of patients with mumps and cultured (Levaditi and Lépine 1948, Klöne 1952) Fanconi et al (1945) distinguish wo types of involvement of the central nervous system—1) meningitis due to the direct damage of the cells by the rus (early type) and (2) encephalitis due to serous non pecific inflammation of the Rössle Eppinger type as a result f antigen-antibody reaction (late type)

It is well known that mumps leaves immunity which s transmissible and can be studied by complement xation, hæmo-agglutination inhibition tests and skin ests. The development of the skin tests is largely due to he work of Enders (1943) By injecting a suspension f parotid gland, obtained from an infected monkey and nactivated at 65°C for twenty minutes, intradermally nto patients who had had mumps he obtained an rythema and infiltration of 1–4 mm in diameter at the ite of injection in almost 100% The reaction lasted two o four days. The injection of parotid gland suspensions from non infected monkeys produced no reaction

According to Enders the skin test is usually positive when done at least a week after the onset of mumps The dermal hypersensitivity may last up to two years after the onset of mumps. On the other hand the reaction is found positive in 50% of people with no history of mumps The same holds for the complement-fixation test.

The practical importance of the skin test is diminished by the fact that monkey parotid glands are not easily obtained. Habel (1945) has got better results with a suspension of egg yolk from infected chick embryos

We report here a simpler method of proving skin hypersensitivity to the mumps antigen It is based on the fact that the virus of mumps is present in the c.s.f of patients with mumps meningo-encephalitis

Investigations and Findings

We used c.s.f of such patients The involvement of the central nervous system was confirmed in these cases by examination of the c.s.f Increased pressure and a slight increase in the amount of albumin were often found, but an increased white-cell count (mainly lymphocytes) was the constant finding At times it was so high that it gave a cloudy appearance to the c.s.f

The samples of c.s.f were initially obtained on the fifth, tenth, and fifteenth days of the illness. They were inactivated at 65°C for twenty minutes and centrifuged at 2000 r.p.m for thirty minutes. The sediment was diluted and injected intradermally

We first tested 72 patients with mumps or with a history of mumps, and 28 without such a history The results differed according to the day of the disease on which the specimen of c.s.f was taken :

C.S.F *obtained on the fifteenth day* was injected into 21 patients with mumps. There was no reaction.

C.S.F *obtained on the tenth day* was injected into 17 patients with mumps No reaction was noted

C.S.F *obtained on the fifth day* was injected into 34 patients with mumps or recovering from mumps and into 28 controls with no history of mumps. As the accompanying table shows, the reaction was positive in all except the controls, the red area measuring 3–10 mm and the zone of infiltration 2–6 mm. In a few cases redness and infiltration reached 2 cm., and in 1 case we observed a blister as big as a pea. The reaction obtained by this method is much more intense than those described for the older methods.

In 150 children at an orphan asylum where there was an outbreak of epidemic parotitis recently, the reaction (with c.s.f taken on the third day of the illness) was positive in 30 (90%) of those who had had mumps in the previous six months, in 19 (74%) of those who had had mumps between six and twelve months previously, and in 26 (65%) of those who had had it one or two years previously The reaction was also positive in 75 (10%) of the children with no history of mumps, but, since the children are orphans an accurate past history was difficult to obtain Even if they had really not had mumps, a positive skin test might be explained on the basis of immunisation by contact with the virus. Enders et al (1945) *obtained positive reactions in 50% of people with* no history of mumps.

By further tests carried out with c.s.f taken during the first five days of the illness we have found that this sample has considerable antigenic properties which are present on the first day of the illness, are greatest on the third day and decrease gradually until they disappear on the tenth day The strongest reaction is obtained during the two or three months after the subsidence of the attack of mumps, but skin hypersensitivity is still present after six months. How long it continues we do not yet know

We have obtained positive reactions with a dilution of 1 in 10 000 The usual dilution which gave us 100% positive reactions was 1 in 10 (see table) (It may be mentioned that the supernatant c.s.f after centrifugation also gave positive but less intense reactions) We are studying how long the c.s.f can keep its antigenic properties We have reasons to believe that when it is kept at 4°C it can remain active for a time.

The specificity of the reaction has been controlled with cross skin reactions. c.s.f from poliomyelitis, infectious mononucleosis lymphocytic choriomeningitis, and chickenpox was injected intradermally into patients with mumps and c.s.f from patients with mumps meningitis was injected into patients with those diseases. No positive reaction was obtained.

Summary

In mumps meningitis the c.s.f has strong antigenic properties Its antigenic potency reaches its peak about the third day of the illness and decreases gradually until it disappears by the tenth day

RESULTS OF SKIN TESTS WITH C.S.F TAKEN ON FIFTH DAY OF ILLNESS

Specimens of C S F kept at a low temperature can probably maintain their antigenic power for some time

Using C S F obtained from patients with mumps meningitis on the fifth day of their illness, in a dilution of 1 in 10, a positive skin reaction was seen in all the persons tested who were suffering from mumps or had a recent history of mumps The reaction was positive as long as two years after the infection

Reactions were also positive in about 10% of children who were not known to have had mumps No reaction was obtained in cases of poliomyelitis, infectious mononucleosis, lymphocytic choriomeningitis, or chickenpox

HEPATIC VENOUS HUM IN CIRRHOSIS OF LIVER

A J S McFadzean
M B Glasg, M R C.P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF HONG-KONG

John Gray
M.A, M D, M Chir Camb, F R C S, F A.C S
SURGICAL SPECIALIST, QUEEN MARY HOSPITAL, HONG-KONG

Venous hum in cirrhosis of the liver was first reported by Pegot (1833), whose patient, an alcoholic ex soldier, presented with a caput medusæ whose centre at the umbilicus was a widely dilated vein as large as an orange The hum was audible over a restricted area of this dilatation in the immediate vicinity of the umbilicus The necropsy findings were described by Cruveilhier (1835) Since then other reports have been published, and Bloom (1950) collected 60 published cases and reported 2 further ones

Catti (1907) and, independently, Thayer (1911) first emphasised the superficial origin of the hum They considered that it was produced in collateral veins in the abdominal wall by the rapid passage of blood through a relative constriction into a dilated segment All subsequent accounts, with two exceptions, have subscribed to this view Huber et al (vide Florand 1922) thought that the first hum which had developed in the case reported by Florand (1922) was due to an arteriovenous shunt, and Bates (1937) considered that the hum in his case resulted from constriction of the inferior vena cava by perivenous hepatic fibrosis—a view first advanced by Gambarati (1903)

While in most cases the collaterals are subcutaneous and visible, in many none are seen In these latter necropsy has revealed collateral channels in or deep to the rectus muscles, and the most frequently encountered localised dilatation lies immediately superficial to the xiphoid process, the area in which the hum is most commonly heard Lutembacher (1936) reported a case in which a venous hum could be heard in two sharply defined areas over the xiphoid process, where no collaterals were visible, and some 2 cm away from a saccular dilatation on a subcutaneous varicose vein At necropsy a large dilated vein was found on the deep aspect of the rectus muscle, and immediately under the areas in which the hum had been heard there were [illegible] dilatations

Those reported cases of venous hum which have established beyond dispute as being produced in colla channels have certain characteristics The hu localised to an area of at most a few centimetr diameter and is not propagated along the vein in whi arises Although varying in intensity it is loud or roaring, continuous, and in most cases increased by inspiration In most cases there is a palpable thrill the site of the hum, and this is invariably present the hum arises in a subcutaneous collateral

We report here a case of cirrhosis of the liver in w a venous hum was heard which differed in many res from that described above and probably had its o in arteriovenous shunts in the liver

Case-record

A Chinese carpenter, aged 32, was admitted to the Ui sity Department of Medicine, Queen Mary Hospit November, 1952 His only complaint was of an abdo mass to which his attention had been drawn by disco while wearing a tight belt some four months before admi

He had been born, and had resided all his life, in Hong Kong and, save for irregular attacks of fever between 1937 and 1945, one of which was established as being due to malaria, his previous health had been good

On examination he was healthy looking, well developed, and muscular The abdominal mass was found to be an enlarged mobile non tender spleen, the lower pole being defined 6 cm below the costal margin in the mid clavicular line The liver was not felt were no visible collateral veins The presence of a amount of free fluid was demonstrated in the abd The only other abnormality detected on physical e nation was a murmur heard over a wide area exte from the right mid axillary line over the lower thoracic cage anteriorly into the upper epigastrium upwards in a narrow area on both sides of the sternu the fourth intercostal space Over the right thora murmur was distant, it became suddenly louder i immediate vicinity of the xiphoid process and when upwards on either side of the sternum it rapidly dimin disappearing above the fourth intercostal space The dis tion and relative intensity of the murmur are depict fig 1 It was a continuous humming sound which in all had a distinct systolic accentuation almost synchronou the radial pulse It was not influenced by the pha respiration, nor was it affected by changes in posture thrill could be detected on palpation

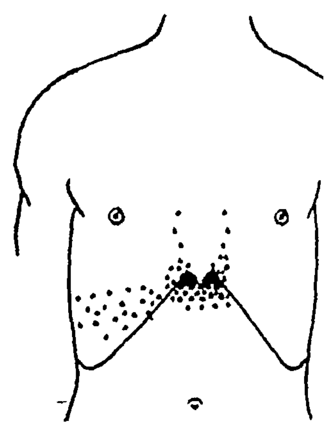

Fig 1—Distribution and intensity of v hum

Investigations—A barium swallow demonstrated presence of œsophageal varices, and the appearanc aspiration liver biopsy were those of a diffuse hepatic fi A blood count showed hæmoglobin 9 2 g per 100 ml., re 3,200,000 per c.mm, mean corpuscular volume 90 c.μ, cells 2200 per c.mm (neutrophils 39%, eosinophils lymphocytes 59%), and platelets 84,000 per c.mm S marrow biopsy showed normoblastic erythropoiesis hyperplasia of both erythroid and myeloid series a increased number of megakaryocytes

Diagnosis—Diffuse hepatic fibrosis and gross splenom with pancytopenic hypersplenism were diagnosed.

Operation—Splenectomy was considered the only trea because there was no history of gastro intestinal hæmor and the amount of the fluid in the abdomen was sma readily controlled. The abdomen was opened through a line incision The liver was smaller than normal and sl diffuse hepatic fibrosis. Running in the falciform ligam

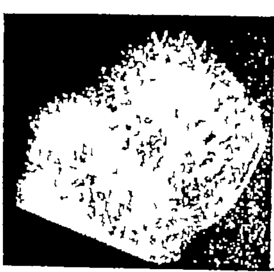

Fig 2—Hepatic arteriogram (left lobe) in reported case of cirrhosis, showing that lipiodol has entered large branches of portal vein, and arterial bed is greatly increased (cf. fig. 3)

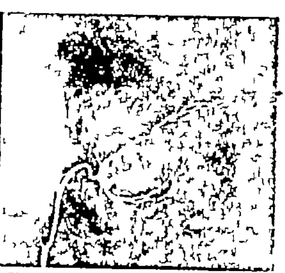

Fig. 3—Hepatic arteriogram (left lobe) in normal liver by same technique as in fig 2.

reach the deep aspect of the right rectus muscle a few centimetres from the xiphoid process was a large vein which was subsequently shown at necropsy to be the left para-umbilical vein. When the liver was retracted from the abdominal wall, the murmur could no longer be heard over the lower thoracic cage but it persisted unchanged in the vicinity of the xiphoid process and on both sides of the sternum It was promptly abolished in those latter areas when the vein in the falciform ligament was occluded by digital pressure The chest-piece of a sterile stethoscope was next applied to the postero inferior surface of the right lobe of the liver and of the quadrate lobe. A murmur was heard identical to but louder than that found on auscultation externally increasing in intensity as the porta hepatis was approached, and heard over the portal vein in the gastrohepatic omentum Light palpation of the portal vein revealed a purring thrill The hepatic artery was isolated and, when it was occluded by pressure between finger and thumb the external murmur and that over the liver and the portal vein promptly ceased. Occlusion of the portal vein did not exert any influence The spleen was removed. After the operation the patient developed an inexplicable peripheral circulatory failure which could not be corrected and he died six hours after the operation.

Necropsy Findings—The dilated collateral vein in the falciform ligament arose in the left branch of the portal vein and ran through the falciform ligament to the posterior aspect of the rectus sheath 3 cm. below the xiphoid process, where it divided into right and left branches, each branch anastomosing with the corresponding internal mammary vein. Incorporated in the wall of the vein close to its origin, but readily dissected from it was the ligamentum teres. The collateral was therefore a greatly dilated left para-umbilical vein. The liver was excised, Lipiodol was injected into the hepatic artery at a pressure of 50 mm. Hg; the liver was radiographed (fig 2) The lipiodol not only outlined the hepatic arterial tree but also entered large intrahepatic vessels in distribution corresponding to that of major branches of the portal vein The demonstration of lipiodol in the portal vein and its branches on dissection clearly established that these large vessels were branches of the portal vein. No lipiodol was demonstrated in the hepatic veins. Fig. 3 shows the hepatic arteriogram produced by the technique employed above in a normal liver excised at necropsy the lipiodol is confined to the arterial tree and does not enter the branches of the portal vein Comparison of figs. 2 and 3 shows a further significant difference: in fig 2 the arterial bed is greatly increased as a result of a great increase in the smaller branches of the hepatic artery The arteriogram in fig 2 might well be likened to a tree in summer and that in fig 3 the normal arteriogram, to one in winter

Direct Auscultation of Cirrhotic Livers

It seemed to us possible that in other cases of cirrhosis of the liver a hum of intrahepatic origin might be audible on direct auscultation of the liver when no hum was heard before laparotomy

9 consecutive cases of non alcoholic diffuse hepatic fibrosis have been investigated In none of these was a hum audible on auscultation before operation. However in 5 cases a continuous humming murmur was heard on auscultation of the postero inferior su of the right lobe and of the quadrate of the liver in each case becoming lo as the porta hepatis was approached 4 of these there was a systolic accentu and the hum was audible over the po vein, light palpation of which reveal purring thrill In all 5 cases the hum when present the thrill ceased when hepatic artery was occluded. In 3 of t cases a large left para umbilical vein demonstrated in the falciform ligam No hum was detected in the remainin of the 9 cases, nor in 10 subsequent ca with macroscopically normal livers, wi were similarly investigated

Discussion

The auscultatory findings at lap otomy and the hepatic arteriogram necropsy establish that the hum the present case had its origin in arteriovenous shu in the liver There is no reason to doubt that the h heard solely on direct auscultation of the liver in th cases of cirrhosis was of similar origin

The hum so produced seems to have been transmit to the parietes by two routes (1) along the large para umbilical vein to the neighbourhood of the xiph process, and thereafter for a short distance along internal mammary veins and (2) via the overly tissue. Since the hum was loudest in the vicinity of xiphoid process and was conducted to this area by collateral vein this mode of transmission seems to the more effective, but the presence of such a collate does not ensure conduction of the hum to the pariet as was seen in 3 of the 5 cases in which a hum was audi only on direct auscultation of the liver

According to Moschowitz (1948) arteriovenous shu in the cirrhotic liver were first demonstrated anatomica by Sabourin in 1885 an observation subsequently co firmed by Epplen (1922) and Popper et al. (1950) T histological observations of Cameron and Mayes (1930) the effects of experimental ligation of the hepatic arte in animals indicated the existence of communicatio between the hepatic artery and the portal vein arteriolar level in the normal liver and Wakim a Mann (1942) concluded, from observations on the tran illuminated liver of living animals, that interconnectio occurred between branches of the hepatic artery and the portal vein at sinusoidal and presinusoidal leve Herrick (1907) first noted the effects of these shunts arterial perfusion experiments on excised normal a cirrhotic livers He found that in normal livers there w a rise in portal pressure of 1 mm. Hg for every 40 mm. rise in arterial pressure, whereas in the cirrhotic liver was 1 mm Hg for every 6 mm Hg rise in arterial pressur Dock (1942) using kerosene as the perfusing fluid, showe that, if the portal vein and the hepatic artery wer perfused simultaneously at a pressure of 20 and 100 mm Hg respectively the rate of flow in the normal liv through the portal vein was 30% less than if the porta vein was perfused alone In contrast, he found that th rate of flow was reduced by 78% in alcoholic cirrhosi The perfusion experiments of Dock (1942) further showe that the degree to which arteriovenous shunts operate i cirrhosis varies widely, being in certain cases of non alcoholic cirrhosis less than in normal livers

Berman et al. (1951) and McFadzean and Cook (1953 have discussed the rôle played by arteriovenous shunt in the production of portal hypertension and, amon others have reported ligation of the hepatic artery i the treatment of portal hypertension This operation ca only be successful in the presence of excessive arterio venous shunting in the liver As emphasised b McFadzean and Cook (1953) where this is not present ligation of the hepatic artery may well lead to the removal of the main, or in some cases the only, blood-supply, with resulting ischæmic necrosis Such cases of necrosis have been recorded If it were possible to demonstrate active and excessive arteriovenous shunts, cases likely to benefit from ligation of the hepatic artery could be selected and those in which necrosis might occur could be excluded In view of the information obtained from hepatic arteriograms at necropsy hepatic arteriography at operation might prove of value, but our radiological facilities are inadequate for this purpose Observations on the influence of occlusion of the hepatic artery on portal pressure directly measured at operation are to be avoided because of a high incidence of portal-vein thrombosis in Hong-Kong Chinese suffering from diffuse hepatic fibrosis Since both these methods are denied us, the demonstration of a hum on direct auscultation of the liver may well prove to be of value in such a selection Although from a small series of cases it is impossible to draw general conclusions, it is of importance to note that 3 patients in whom a venous hum was heard over the liver at laparotomy had the hepatic artery tied and subsequently progressed satisfactorily, whereas 1 patient in whom no such hum was heard underwent the same operation and died from hepatic necrosis

The greatly increased arterial vascular bed seen in fig 2 is of great interest This increase has been found not only in other cases of diffuse hepatic fibrosis but also in biliary cirrhosis and primary carcinoma of the liver The full significance of this finding is under investigation and evidence is accumulating that suggests that the greatly increased arterial bed plays an important part in the genesis of ascites in these three conditions

Summary

In a case of diffuse hepatic fibrosis a venous hum was heard over a wide area A similar but louder hum was heard on direct auscultation of the liver at operation Occlusion of the hepatic artery abolished the hum Hepatic arteriography at necropsy showed numerous arteriovenous shunts between branches of the hepatic artery and of the portal vein, and it is concluded that these shunts were responsible for the hum

Direct auscultation of the liver at operation revealed a hum in 5 of 9 cases of diffuse hepatic fibrosis in which a hum was not heard previously In the absence of facilities for hepatic arteriography at operation a hum so demonstrated may aid selection of cases for treatment by ligation of the hepatic artery

A greatly increased arterial vascular bed was seen in the arteriogram of the case recorded This increase has been found not only in other cases of diffuse hepatic fibrosis but also in biliary cirrhosis and in carcinoma of the liver

We wish to thank Prof Hou Pao Chang, of the department of pathology, University of Hong Kong, and Dr H. C Ho, senior radiologist, Queen Mary Hospital, for their coöperation.

RIGHT-SIDED THORACIC APPROACH FOR COMBINED LOBECTOMY AND MITRAL VALVOTOMY

K M SHAW
M B Dubl, F R C S I

LATE SURGICAL FIRST ASSISTANT, LONDON CHEST HOSPITAL

THE operation of mitral valvotomy for mitral stenosis has rapidly become established as a routine procedure with a standardised technique The early approach through an anterior thoracotomy with the patient supine has been largely abandoned in favour of the more direct posterolateral thoracotomy through the left pleural space, with the patient in the right lateral position. The pericardium is opened widely, and the mitral valve is approached through an incision in the auricle of the left atrium

So far as I can ascertain, no report has been published of an approach to the mitral valve through the right pleural cavity It is easy to conceive of a situation where such an approach would be advantageous, as in the following case

CASE-REPORT

The patient, a small frail woman aged 52, presented with cough and pain in the chest and was found to have an undifferentiated carcinoma of the lower lobe of her right lung. Preoperative examination revealed mitral stenosis, although she had previously been in good health with no symptoms of heart disease This was confirmed by a cardiologist, who found the heart slightly enlarged, with evidence of right ventricular hypertrophy, the heart was in regular rhythm, and there was no evidence of congestive failure He agreed that thoracotomy was justifiable after preliminary digitalisation

Operation —A right posterolateral thoracotomy was done through the bed of the fifth rib, with the patient in the lateral position There were no obviously invaded hilar glands, and lower and middle lobectomy was done without difficulty The patient's general condition had given some anxiety from the induction of anæsthesia, and during the pulmonary resection auricular fibrillation began It was thought that recovery might be facilitated if the mitral stenosis could be relieved. The pericardium was opened round the stump of the inferior pulmonary vein, and a clamp was placed on the left auricle at the base of the vein, from which the ligature was then removed The tip of the right index finger was next inserted into the vein, and the clamp removed The lumen had to be stretched considerably before the finger could be wholly inserted into the auricle There was slight regurgitation *from the mitral orifice, which was as large as the finger tip* The commissures were easily split to admit the finger The posteromedial commissure was split further, but on the attempt to split the anterolateral commissure further the valve moved away to the left before the finger, and no purchase could be obtained The final aperture was estimated to admit two fingers On removal of the finger the clamp was replaced on the auricle and the vein closed with a continuous fine silk suture The chest was closed in routine fashion with drainage, and the patient's condition was much improved at the end of the operation

Pathology —Section of the growth confirmed the diagnosis of undifferentiated carcinoma without evidence of gland invasion

Convalescence was uneventful, the patient being up on the fourth and discharged on the sixteenth postoperative day She was examined by a cardiologist before discharge, and it was considered that the signs of mitral stenosis were less evident than before the operation There were a slapping first sound and only a faint diastolic murmur, auricular fibrillation was still present

COMMENT

Mitral valvotomy through the right inferior pulmonary vein after lobectomy is feasible and technically simple, providing finger pressure is sufficient to separate the fused commissures

This patient was under the care of Mr J R Belcher, to whom my thanks are due for permission to publish her case-record

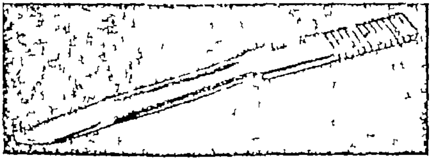
New Inventions

ELEVATORS TRANSPARENT TO X RAYS FOR SMITH-PETERSEN NAILING OPERATIONS

A DISADVANTAGE common to bone elevators or xtractors normally used during operations for insertion f Smith Petersen nails and allied procedures under X ray control is that they have to be removed each time adiographs are taken, or else they may spoil the ilm.

Trauma and time may be spared by using elevators hat may be left in situ throughout the operation

The type shown here is not unlike the Bristow bone ever, but the shape may be altered when necessary to enable it to remain in the wound when films are being taken The material used is polymethyl methacrylate * (unplasticised) having the following qualities it can be sterilised by boiling it is slightly malleable when very hot, and it resumes its original shape after boiling



These elevators are made by Allen & Hanburys Ltd., 48 Wigmore Street London, W 1,

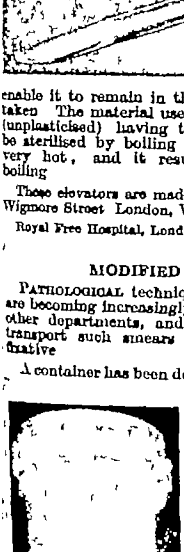
Royal Free Hospital, London

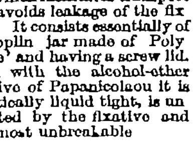
ROY H MAUDSLEY
F.R.C.S

MODIFIED "COPLIN JAR

PATHOLOGICAL techniques involving wet-fixed smears are becoming increasingly common in gynæcological and other departments, and it is sometimes necessary to transport such smears while still immersed in their fixative

A container has been devised which facilitates transport and avoids leakage of the fixative It consists essentially of a 'Coplin jar made of Polythene' and having a screw lid. Used with the alcohol-ether fixative of Papanicolaou it is practically liquid tight, is unaffected by the fixative and is almost unbreakable





The design was submitted to A. R. Horwell 18 Christchurch Avenue, London, N W 6 who has arranged for its manufacture.

Reviews of Books

Social Medicine

S LEFF, M.D, D P H., barrister-at-law London Routledge & Kegan Paul. 1953. Pp 297 28s.

SINCE the Goodenough report et al., it has been fashionable at medical hunt breakfasts for the Master in the Leacockian manner, to stride to the sideboard drain a dipper of Social Medicine, and gallop off in all directions. The dust wrapper of Dr Leff's book promises us "a completely new approach to the subject,' but it is in fact a forcible and well-documented plea for more attention to be paid to social factors in health and disease and as such is in the direct and grand tradition of Chadwick, Southwood Smith, Farr, Simon, Ryle, and Winslow This is by no means to say that it was not needed and need not be read

After discussing (but failing to define) social medicine Dr Leff relates his subject to the background of history, and sets out his thesis that the most promising field of advance in medicine today is by the application of social measures *This he illustrates by chapters on the infectious diseases* death rates, housing nutrition working conditions tuberculosis, rheumatism, mental disorder the aged war, and the health services. It is not a textbook, but special pleading of a high order The sections on the results of statistical research, on conditions of work on mental disorders, and on the effects of atomic explosions are particularly good. Perhaps the most valuable is that on the health services which includes an attack on excessive specialisation His illustrations of the economy resulting from preventive programmes may be commended to ministers of health in all countries. 'The question is not whether we can afford to carry out these social reforms, but whether we can afford *not* to carry them out.' Dr Leff is convinced that medicine is facing a crisis (it always is, of course), and that social medicine is one of our main weapons in the battle against disease, both in the struggle for the elimination of adverse social factors and for the advancement of the theory and *practice of medicine. It is the medicine of the future* emerging from the medicine of today" Whether we go the whole way with him or not, this book can profitably be read by all concerned with the future of medicine

Hormonal and Neurogenic Cardiovascular Disorders

Endocrine and Neuro-Endocrine Factors in Pathogenesis and Treatment. WILHELM RAAB M.D. F.A.C.P F.A C.C F C.C.P professor of experimental medicine and head of cardiovascular research unit, University of Vermont. Baltimore: Williams & Wilkins London Baillière Tindall & Cox. 1953 Pp 722. 114s

As Professor Raab points out, it is one thing to admit the existence of certain facts and another to incorporate them as tools into one's daily reasoning In writing this book, however he has clearly carried the process a long way In the first section he surveys the effects of individual hormones, such as thyroid, pituitary extract noradrenaline and adrenaline, on the cardiovascular system. In the second he recounts the cardiac manifestations of the differing endocrine syndromes, including phæochromocytomas In the third section he discusses the influence of hormonal and endocrine effects on various cardiovascular syndromes, such as angina pectoris and congestive cardiac failure His intention has been to struggle out of the dead end street of exclusively mechanistic thinking in matters of cardiovascular pathology and therapy ' In this he is right for little more can be deduced about the fundamental causes of heart-disease from hæmodynamic and electrocardiographic observations: advance now depends on study of the profound metabolic upsets seen in congestive failure, the severe cardiovascular disturbances in endocrine disorders, such as phæochromocytoma, and the fundamental changes wrought by corticoid therapy In particular he has been concerned with the possible rôles of noradrenaline and adrenaline and the ways in which *they are inactivated* or potentiated by abnormal states in the body, with consequent effects on the cardiovascular system. It is a little difficult to accept some of his arguments, many of which are based on biochemical measurements which are not yet sufficiently accurate This does not in any way deny the force of his general theme, in support of which he has provided a complete review of all the non-mechanistic factors affecting the heart Few important references can have been omitted from the 3700 he supplies, of which more than 70 apply to his own work Though his English at times is difficult to follow, all cardiologists should read this book

Ear, Nose and Throat Diseases for Medical Students

WILLIAM MCKENZIE, M B Camb, F.R C S, surgeon, Royal National Throat, Nose and Ear Hospital Edinburgh E & S Livingstone 1953 Pp 256 21*s*

THERE are two features of this new book that will immediately commend it to the medical student—its size and its price There are also many good things in it—pleasant production, a useful list of E N T questions set in the qualifying examinations of London University and the Conjoint Board, brief illustrative case-reports, and some good photographs of the methods of clinical examination But there is far too little on the basic sciences, the important subject of cancer is dismissed in the short space of 11 pages, much of which is devoted to photographs of advanced cases, while early symptoms are inadequately described, no description or illustrations of tracheotomy tubes are given in an otherwise good description of the operation, and one statement in particular is a dangerous exaggeration —that "a careful history is more important than any examination by special instruments"

A Dictionary of Midwifery and Public Health

G B CARTER, B SC, S.R N, S C M, M T D, and G H. DODDS, M D, F R C S, F.R.C O G London: Faber & Faber 1953 Pp 686 25*s*

Miss Carter and Miss Dodds have written this book primarily for midwives, but they hope—and on good grounds—that it will be of use to other workers in the public-health field, and also to medical students It is much more than a dictionary of terms, though it is that too, but the definitions are supported by explanations, so that it has more of the nature of an encyclopædia than a dictionary (and indeed it is the offspring of an earlier work, the *Midwife's Dictionary and Encyclopædia*)

Thus the entry headed "hæmolytic disease of the newborn" is a little article filling 5¹/₂ columns of text, giving a clear and up to date summary of rhesus sensitivity, types of hæmolytic disease, prophylaxis and treatment, and ending with a cross-reference to "rhesus blood groups" In the same way, "uterine inertia" is dealt with in an informative and practical article of 7 columns, and the same principle holds throughout the book It has evidently been put together with great care and labour, and the terse clear sentences are a pleasure to read Occasional line drawings, equally clear and economical, illustrate the text The section on public health and administration occupies some 130 pages at the end of the book, and deals mainly with those aspects of public health which affect pregnant women, infants, and growing children

The Breast in Roentgen Diagnosis

RAUL A LEBORGNE, M D, head of the radiologic department, instituto de Radiologia y Centro de Lucha Contra el Cancer—Hospital Pereira Rossell, Montevideo, Uruguay Translated by Lucy Crocker de Leborgne Montevideo Impresora Uruguaya, S A London Constable Pp 194. 63*s*

IN this country radiography has not so far been found a useful means of diagnosing breast lesions Dr Leborgne's book suggests that this may perhaps be the result of insufficient attention to technique It consists largely of X-ray pictures, supported by photographs of specimens and slides, and makes a good case for a much more thorough trial of radiography in this field He finds straight radiographs of the breast the most generally useful, particularly for neoplasms in the breast substance Contrast radiography, after injection of the ducts with a dir opaque medium, is employed for the diagnosis of duct lesions, particularly of those which produce a nipple discharge without other clinical signs

In a short opening chapter on technique he describes intraductal biopsy by means of fine wire loops introduced into the duct openings after they have been dilated with a small laminaria tent, this is the sole example in which technical virtuosity seems to outrun utility Normal radiological appearances are discussed in the second chapter The secreting and fibrous tissue of the breast are more opaque than the surrounding fat, and the value of straight radiographs depends on this fact In young women, especially when they are lactating, the predominance of secreting tissue makes radiology less useful than it is when advancing age has brought infiltrations of fat The third and longest chapter deals with carcinoma of the breast Malignant tumours show up as opaque masses with a spiculated edge and thickening of the neighbouring ligaments of Cooper—points which are well seen in the illustrations, and contrast strikingly with the smooth edge of benign tumours and cysts. Thickening of the skin over malignant tumours may also be seen, and a characteristic spotty calcification is sometimes apparent, especially in duct carcinomata Short chapters on cystic disease, fibro adenoma, infective mastitis, and certain rare conditions occupy the rest of the book

Dr Leborgne has found an able translator in his wife, who writes proper English prose, with only an occasional word to which we are not yet accustomed The 307 photographs and diagrams, all in black and white, are well reproduced

Atlas of Medical Mycology

EMMA SADLER MOSS, M.D, director, department of pathology, Charity Hospital of Louisiana, New Orleans, and ALBERT LOUIS MCQUOWN, M D, pathologist, Our Lady of the Lake Sanitarium, Baton Rouge, Louisiana. London Baillière, Tindall, & Cox 1953 Pp 24, 61*s* 6*d*

AN atlas of medical mycology should not be merely an illustrated textbook, and it cannot be a substitute for a textbook Special care is required in the selection of the illustrations to ensure that they fulfil the peculiar purpose of the atlas, showing clearly the characteristic features of the subject, whether clinical, pathological, or mycological In some instances, coloured reproductions may be necessary

In this work the authors have presented a collection rather than a selection of photographs, and though some are good others are disappointing, and a few could be identified only by reference to the legend The general plan of the book is sound, and with better illustrations it should make a valuable atlas

---

Textbook of Pathology (6th ed. London Henry Kimpton. 1953 Pp 1024 88*s*)—"In 1951," says Prof. William Boyd in the preface to the sixth edition of his well-known textbook, "over 73,000,000 pounds of synthetic chemicals were administered with or without good reason in the United States, or half a pound for every man, woman and child in the country", and he mentions in passing that the wholesale change in the normal bacterial flora of the bowel produced by antibiotics "may have dangerous or even fatal consequences." As the author of a text on pathology he has his own reasons for feeling testy about the modern appetite for drugs diseases which were formerly common and fatal have disappeared or become relatively trivial, and new diseases have appeared in their wake, and it all makes a lot of work But a man who produces a large textbook and then revises it six times in 20 years is a glutton for work in any case, and his stupefying list of new material suggests that no student need fear (or hope) that he has left anything out

An Atlas of the Commoner Skin Diseases (4th ed. Bristol John Wright London Simpkin Marshall. 1953 Pp 371 75*s*)—Dr Henry Semon's admirably illustrated book has for nearly twenty years been giving a very helpful hand to those who find skin conditions a recurrent cause of perplexity A number of new photographs have been added in this latest edition, but the majority are those originally prepared under the direction of Dr Semon's collaborator, the late Dr Arnold Moritz They will long stand as a tribute to his outstanding skill at this work.

THE LANCET

LONDON SATURDAY, NOV 28 1953

Operating-theatre Infections

DESPITE the aseptic ritual of even a well run operating theatre, surgical wounds are probably contaminated more often than the surgeon believes The contamination is seldom clinically significant, however either because the organisms introduced are not pathogens or because they are not too many for the tissues readily to destroy them The skill of modern operating and the efficacy of chemotherapy have further reduced the risks of minor contamination of deliberate wounds This means however, that the postoperative infections which still supervene are more likely to have such tragic consequences as those described in two recent reports. One of these recounts the death of an 18 year old girl from tetanus after appendicectomy [1] The other, to which Dr SEVITT refers in his article on an earlier page, concerns a man of 26 who fractured and dislocated his left ankle at football, and lost his leg above the knee because gas-gangrene caused by *Clostridium welchii* followed an open operation on the ankle The source of the girl s infection was not settled but Dr SEVITT's inquiries into the case of the young footballer leave little doubt that the infection resulted from the exhaust system of ventilating the operating theatre This conclusion is strengthened by the evidence in SEVITT s earlier report [2] that the same ventilation plant, by causing aerial dissemination of tetanus spores, was responsible for two cases of postoperative tetanus, one of them fatal In 1946 ROBINSON et al [3] reporting two fatal cases of postoperative tetanus, emphasised the need to exclude infected dust from operating theatres

What can surgeons do to eliminate this small but deadly residue of postoperative infections? However many of the details of sterilisation they must inevitably delegate to theatre-sisters and staff nurses, they should satisfy themselves about the measures taken in their theatres to ensure the sterility of gowns masks, swabs packs, dressings gloves, talc penicillin and other powders solutions lotions local anaesthetics, syringes, and so forth The measures must be adequate in the first place and the understanding and efficiency of those who carry them out ought to be checked periodically In particular it is essential to make sure that the theatre autoclave is used properly If drums are too tightly packed, or if a proper vacuum is not established and maintained before turning on the pressure, the temperature needed for sterilisation may not be reached in all the material within the steriliser This point can be simply checked by including in the steriliser, and later submitting to the laboratory for culture a suitably wrapped test swab which has first been contaminated with dust known to contain sporing organisms From the accidents already cited, it is evident that surgeons should al look into the possibility of dust being disseminated l the ventilating system of their theatres As D SEVITT emphasises, the real villain of the piece is th exhaust type of ventilation which sucks air and du from the hospital and theatre corridors and from oth parts of the hospital, into the operating theatre, that the theatre becomes an " air sewer " draining in itself dust often contaminated with sporing organism Upward draughts towards the vents suck floor du into the air and every wound in such a theatre exposed to serious risk of dangerous contaminatio BOURDILLON and COLEBROOK [4] devised a speci dressing unit with a system of ventilation whic delivers filtered warmed, and humidified air from th ceiling The air, which is extracted at floor level, changed 10–20 times per hour without discomfort occupants of the room. This plant is expensive put in and to run, but it should be at the very least guide to the design of the ventilation for futu operating theatres, and its costs must be measure against the disasters caused by a method of ventilatio now clearly and tragically established as dangerou Until a completely satisfactory system of ventilatio can be installed in all theatres there is need to reduc the dangers from existing conditions Operatin theatre floors and walls should be regularly dust with damp cloths wrung out of antiseptic solutions precautions should be taken against introduction infected dust on the footwear of those coming into th theatre preferably by their putting on gumboots some equivalent which have been left standing in stron antiseptic and hospital corridors and blankets shoul be oiled to reduce dust dissemination in hospital But perhaps the most important thing is to tackle th present exhaust systems of theatre ventilation. F example it has been suggested [5] that extractor fa may be reversed so that they draw air into the theat through their ducts, which can readily be guarded b fitting them with air filters This produces a outward draught of air through the doors of th theatre into the hospital corridors Such a relativel uncontrolled method of disposing of warm air an steam from the theatre is not ideal, but it would no be a bad thing perhaps if the unpleasant visibl consequences of its use drew attention to the need for proper system of theatre ventilation It is better t accept the disadvantages of this simple expedien than to tolerate unmodified a system which has bee proved dangerous to the lives of patients

Civilised—and Sedentary

OCCLUSIVE coronary heart-disease is often regarde as one of the disorders of civilisation. Its appare predilection for the medical profession has led to it being called the doctors disease with the flatterin suggestion that doctors are particularly civilise A popular view is that the greater prevalence of th and some other conditions reflects the greater stres of modern life In a sense this is a truism an rapid increase in incidence is likely to depend o environmental changes, and any disease provokin change may reasonably be called a stress. Bu those who use the phrase are probably thinking mor generally in some way, they imply, we get a tougher break from life than our ancestors did

[4] Bourdillon R. B., Colebrook, L. *Ibid*, pp 561 601.

[5] *Army med Dep Bull.* 1941-4 [illegible] p [illegible]

The increase in occlusive coronary heart-disease is real, if hard to estimate MORRIS[1] has pointed out that, though better diagnosis and treatment should have reduced deaths from (for example) cardiac rupture these are in fact becoming more frequent On the other hand he showed that severe atheroma is, in contrast, becoming less common This suggests that occlusion is a complication and not an integral feature of atheroma , and we should therefore separate the two problems—the cause of atheroma, and the cause of thrombosis (or other occluding process) in atheromatous vessels Much work, mostly American, on the first problem has produced a strong case for regarding atheroma as a sequel of disordered lipoid handling[2] Broadly speaking, the suggestion is that the arteries are not quite watertight, that there is continual leakage of plasma into the venæ vasorum and adventitial lymphatics, and that the less soluble lipoid *moieties of lipoprotein complexes will tend to* be sieved out in the intima The outward flux will be greater where the blood-pressure is higher, and lipoid trapping will be assisted by endothelial thickening or local lymphatic obstruction This would explain the concentration of atheroma in the lower aorta or over regions of aortitis, and its occurrence in the pulmonary artery only when the pressure there is raised But the most important variable, it is thought, is the state of the plasma-lipoids The concept is that each individual consuming a given number of calories can safely handle a certain quantity of dietary cholesterol (mostly from eggs and other dairy produce) , but, if this is exceeded, the normal lipoid transport will be overloaded and a more "atheromagenic" type of lipoprotein will appear in the blood The dietary cholesterol threshold is probably lowered by an excess of total calories and also by such diseases as hypothyroidism and diabetes Whether right or wrong these views are more likely to stimulate therapeutic research than the picture normally offered to British students of an inevitable furring of the pipes with age As the dangerous foods are expensive in peace and scarce in war, a greater prevalence in the well-to-do and a decrease during rationing periods are to be expected

In an article concluded in this week's issue Dr MORRIS and his colleagues produce important new evidence about the incidence of occlusive disease By comparison between occupations within the same social group but involving different grades of physical exertion, they show that the disease is commoner in the more sedentary workers It is also more severe more die in the first occlusive attack and fewer escape major infarction to present as angina of effort Does this greater prevalence among the sedentary reflect more atheroma or some other factor favouring occlusion in atheroma ? If the former, is there a difference in eating habits between the active and sedentary workers ? This seems unlikely, but a sample comparison would be worth making The more general findings of MORRIS and HEADLY[3] may provide a clue They found that sedentary workers show an excess of deaths from quite a number of disorders (including appendicitis, diabetes, and duodenal ulcer) which have been regarded as diseases of modern life

If *the excess of coronary disease in light* workers is not due to more atheroma, our tentative conclusion must be that, while atheroma follows faulty diet, the likelihood of occlusion is increased by sedentary habits It will be interesting to see how readily these notions are accepted by the profession Doctors who smoke have been moved to unparalleled subtleties of statistical exegesis in their efforts to prove that the cause of the commonest cancer has not been discovered Will they welcome the idea that the stresses of modern life that give them coronary disease are the outcome of unwise eating and deficiency of exercise ?

Mumps Sensitivity Tests

ALTHOUGH typical cases of mumps with involvement of the salivary glands may be diagnosed readily enough, there are circumstances in which immunological tests of infection or resistance to infection are of value During attacks of mumps and the subsequent convalescence, specific antibodies to the virus appear in the serum and are detectable by complement fixation methods[1] Using the allantoic fluid from fertile eggs infected with mumps virus, two antigens participating in the complement fixation reaction have been prepared[2] One of these, designated S, is regarded as the soluble antigen and is obtained from the supernatant fluids, whilst the other, the V antigen, is associated with the virus bodies themselves During an attack of mumps, antibodies to the S antigen appear in the blood before V antibodies , and, since S antibodies appear within a week of infection,[3] their presence in the serum is a help in early diagnosis, Antibodies to the S and V antigens persist in the blood for 9–18 months, and when they are detected a mumps infection within this period can be presumed The mumps virus agglutinates human and chicken erythrocytes, and in cases of mumps the serum contains antibodies inhibiting the hæmagglutinin[4] The antihæmagglutinins appear in the blood-stream soon after the complement-fixing antibodies, but the value of the test is limited by the instability of the antigen used for the test

After a patient has recovered from mumps his skin is hypersensitive to inactivated mumps virus, and this reaction is apparently unrelated to the development of complement-fixation antibodies For the skin test, the virus used has been obtained either from the parotid glands of infected rhesus monkeys or from infected fertile eggs , and it has been inactivated by heating or by treatment with formalin[5] On another page of this issue Professor CHOREMIS and his colleagues in Athens report that the cerebrospinal fluid of patients with mumps meningitis can be used as the source of antigen for skin-testing The heated centrifuged deposit from cerebrospinal fluids taken on the fifth day of the disease was found to produce skin reactions in patients with mumps and in those who had lately recovered from the infection. Positive skin reactions were obtained in 90% of the children who had had mumps within the previous six months, but in only 74% of those whose attack had been between six and twelve months previously

[5] Enders J F , Kane L W , Maris, E P , Stokes J jun. *J exp Med.* 1946, 84, 341

The hypersensitivity shown by the skin reaction is evidence of resistance to mumps following previous infection and it is therefore of value in excluding the possibility of the disease developing in these people when they have been exposed to infection [6] The test is also useful in implicating the mumps virus as the cause of an orchitis or a meningitis, when the hyper sensitivity develops two or three months after the infection A considerable proportion of patients with mumps show some involvement of the nervous system and in some cases there may be meningo-encephalitis without swelling of the salivary glands Although the skin tests or serological reactions are clearly of value when used in this way, there has lately been a tendency to discourage tests of skin hypersensitivity, because the reaction may be late in appearing and because the material injected may itself stimulate the production of complement-fixing antibodies in non infected persons

Epidemiology of Influenza

INFLUENZA viruses, and particularly influenza A viruses, are notoriously variable in their antigenic characters, and there are two views about the pattern of their variability Some virologists believe in continued antigenic novelty they consider that the antigens are undergoing progressive modification from one epidemic to the next older antigens being gradually replaced by newer ones every few years Others think that the influenza viruses contain a finite number of antigenic components, which undergo quantitative changes or rearrangements within the virus particle from one epidemic to another and Prof T FRANCIS of Ann Arbor speaking last week to the section of epidemiology of the Royal Society of Medicine, made it clear that he belonged to this second school. A decision between these two possibilities has practical significance, for it would determine policy in the use of influenza vaccines. If there are a finite number of virus antigens, it is conceivable that the antigenic changes will pursue a circular course, and we may be confronted once more with the influenza viruses of two or three decades ago With this possibility in mind, Professor FRANCIS would advocate including early as well as recent strains of influenza virus in current vaccines. Two types of investigation in his laboratory have a bearing on this viewpoint. The first is a study, with virus-absorbed antisera, of representative strains of influenza virus recovered during the past twenty years Among the strains examined a number of antigens could be identified, and there was clear evidence (as in other studies [7]) of the gradual appearance and disappearance of antigenic components. Recently isolated strains were far removed antigenically from the strains of twenty years ago, but some strains recovered in 1947 were intermediate in character between older and more recent strains Until now the change has appear be unidirectional. The second investigation was cerned with antibodies against representative influ strains, of the last two decades, in some 2000 speci of sera taken from people of different ages Prof FRANCIS found that children's sera showed anti against recently isolated strains only, while sera older people showed antibody mainly against viruses prevalent at the time when they might first contracted influenza This interesting and u pected finding falls into line with the studies on antigenic characters of the viruses, but it also sugg that people tend to respond to infection with influ virus by producing more antibody against the st of virus which first attacked them rather antibody against the current strain The implicat of this finding in relation to influenza immu both natural and artificial will require car evaluation

Another conclusion from this work is that viruses of swine influenza which are antigenica related to earlier strains of human influenza A w prevalent at the time of the 1918–19 influenza p demic ANDREWES et al [8] found in 1935 that s from children under 10 unlike sera from adu contained antibody against human but not sw influenza virus, and, basing his view on this obser tion, LAIDLAW [9] suggested that the virus of sw influenza became established in swine during 1918–19 pandemic STUART HARRIS et al [10] tested s from St Helena which had escaped the pandem the islanders had low levels of antibody to the sw virus but, after a mild influenza epidemic th in 1936 antibodies appeared in the sera of a numb of them. The conclusion was that the swine influen antibodies might merely represent a broad antiger response to a related virus, and there was experiment evidence of the ferret's immunological response infection to support this belief Professor FRANCIS results support the alternative interpretation th swine-influenza viruses were prevalent during the fe years before and after the 1918–19 pandemic and th a highly virulent mutant of that antigenic make-u was responsible for the pandemic On this hypothes the St Helena population might have been infecte earlier with a less virulent strain of the swine-influenz type

At the same meeting Prof. C H STUART HARRI described the investigation which he and his colleagu carried out during last winter's influenza outbrea in New York State Sera were collected at interval from a number of districts in different parts [illegible] State, and they were tested for evidence of [illegible] infection by the complement-fixation test [illegible] antigen In this test a positive result [illegible] indicate recent infection, since complement-fixing antibody, unlike neutralising [illegible] to disappear fairly rapidly after infection [illegible] areas investigated, influenza was not [illegible] winter but reports were received from [illegible] of increased numbers of cases during February and March. This peak coincided with [illegible] in the numb of positive sera which [illegible] from about

during December and January to about 15–20% of the samples tested during February and March, and in the following months this proportion declined considerably In further investigations of this type it would be necessary to show that samples taken in the preceding summer had practically no antibody Meanwhile, these results suggest that there may be a wide seeding of virus in the form of subclinical infections a month or two before an actual outbreak As Professor STUART-HARRIS remarked, there may be a connection between these results and ANDREWES's postulated "basic" inter-epidemic virus[11], and this is clearly a point worth investigating

In the search for influenza virus in subclinical infections, it would be important to have a screening test for determining which washings or garglings are likely to yield virus The nasal-inhibitor test of FAZEKAS DE ST GROTH[12] would be suitable for this purpose, but Dr B E ANDREWS told the meeting that technical difficulties in its application necessitated further investigations He described the laboratory tests and Dr J C MACDONALD the clinical examinations made during a vaccination experiment in a Luton factory last winter They were encouraged to find good agreement between clinical and laboratory tests in most cases In addition to the influenza A one case of influenza C was suspected on serological grounds, if confirmed this would be the first case reported in this country

The news and views put before this meeting prompted Dr F O MACCALLUM to remark that though it was twenty years since the influenza virus was first recovered in the laboratory, this field of research had lost none of its life And it was encouraging to note that many laboratories in this country are hard at work, either on their own account or as part of the international programme of research organised by the World Health Organisation A report,[13] lately published in Geneva, shows clearly the extent of last year's world-wide influenza epidemic and illustrates in vivid terms the size of the problem. The influenza virus intends to keep us busy for some time to come

COUNTER-ATTACK ON SMOG

To say that every day tons of soot and grit fall on our industrial towns is not a pleasantry but a fact In 1950–51 the London County Council placed collecting-trays at four points in mixed residential and industrial districts, and other trays in the neighbourhood of power-stations The average deposit in the first four areas was found to amount to about 1 ton per sq mile per day which seems plenty, until it is realised that in the neighbourhood of power stations the figures ranged from 1 to 79 tons per sq mile in summer and from 4 to 72 tons in winter The three power-stations of Fulham, Lots Road, and Battersea lie within a circle with a radius of a mile, and their coal consumption is nearly 2,000,000 tons a year There was a time when it was the boast of employees at one of these great power-stations that a white plume about a yard long was all that anyone could see coming from the noble chimneys Now the picture has changed to that described by Dr Horace Joules in a recent letter[1] The London County Council, in a statement of evidence[2] to be submitted to the committee now inquiring into the causes and effects of air pollution (the Beaver Committee), say that when a power-station is to be built they have always pressed for the installation of the most efficient means of preventing the discharge of soot, ash, grit, and gritty particles, and that they have also pressed for remedial equipment to be installed in the older power-stations, to mitigate the nuisance The failure of their efforts to change the face of London they attribute in part to the difficulties arising from the use of coal containing a higher proportion of ash than the grit arrestors can cope with However it may be with power stations, Mr John Fox, in the current issue of *Smokeless Air*,[3] claims that steam raising factories can burn low grade fuel—and even the reviled "nutty slack"—efficiently and without smoke, provided they install suitable stoking equipment Such equipment is expensive, and he regrets that combustion equipment has been specifically excluded from the Government's loan scheme for increasing industrial efficiency

Power stations and industrial firms contribute only half our smoke domestic fires provide the other half. Here the use of smokeless fuels should help, but it offers no complete or immediate answer As the Earl of Selkirk[4] pointed out in the recent debate in the House of Lords, less than 1 million tons of smokeless fuels are put on the domestic market every year, as against 35 million tons of coal and 3 million tons of coke. We should get less smoke if householders used coke for heating, but coke cannot be burned in the old fashioned grates which are still the commonest types, and smokeless fuels cost more than coal or coke The L C C suggest that the Government should do everything possible to ensure that ample supplies of smokeless fuel are made available at a competitive price Even that, however, would not rid our atmosphere of sulphur compounds

When coal is burned most of the sulphur goes up the chimney in the form of sulphur oxides, to be carried into our lungs on foggy days, dissolved in water vapour, as the most lethal components of fog and smog In big plants the sulphur compounds can be very largely removed from flue-gases by washing, but this process costs 8–10s per ton of coal burned The flue-gas washing plant at Fulham power-station was allowed to go out of use during the war and has not been reinstated. Because of the difficulties of keeping such plants in operation, and the high cost of the process, flue gas washing, the L C C say, is not economically practicable for ordinary industrial firms Even for power stations it may have its drawbacks the British Electricity Authority argue that the discharge of hot gases from high chimneys is likely to ensure much wider (and therefore less harmful) dispersal of sulphur compounds than is the discharge of cool washed gases, and that when weather conditions favour fog, such washed gases are much more likely to hang about the power station and increase the percentage of sulphur oxides in the a than are gases carried off unwashed and piping ho On the other hand, it has been shown conclusively th gas-washing has reduced the concentration of sulph dioxide in the neighbourhood of Battersea pow station The L C C recommend the better clean of coal at the pits (which would remove some of sulphur compounds), and ask for power to sample fl s from shafts suspected of causing heavy pollution y also think powers for the establishment of smoke zones should be less cumbersome, and they urge need for speedy investigation of the many problems ch smoke abatement presents.

leanwhile, to citizens threatened with smog the long n preventive aspect appeals less perhaps than the k therapeutic measures proposed by Mr N Pilpel,[5] search scientist at King's College, London These e been submitted, on his behalf to the Beaver Com tee by the chairman of the scientific advisory council the Ministry of Supply Mr Pilpel suggests that y weak solutions of surface-active materials made with traces of 'seeding agents,' and sprayed finely n aircraft, could cause the water droplets of fogs to lesce and *fall as rain—carrying with them the soot,* and sulphur dioxide which they are supporting ding agents—such things as silver iodide, dry ice, l salt—spread, it seems, into cold clouds and drive supercooled water droplets together as snow but s only happens efficiently if the temperature is 10°C more below zero Since fog clouds are not cold enough respond in this way, Mr Pilpel suggests that such face-active *agents as the common soapless detergents* ld be used, either in conjunction with seeding agents separately They are already used in industry to rcome similar temperature difficulties The amounts ded would be so small that the cost of fog clearance uld be very low It all sounds too good to be true ence, however has now concentrated successfully almost every subject except ethics and the weather s may be an indication of an advance into new fields

THE E.E.G. AND THE MIND

THE relationship between electro encephalic changes d psychological disorders is far from clear Kennard[6] reviewed published reports with a view to answering ree questions (1) are abnormal E.E.G patterns mmon in patients with primary mental disorders who ve no other evident organic disorder of the nervous stem ? (2) to what factor or factors might such a fference be due ?; (3) of what significance is this fference ? Defining normality of the E.E.G is not sy, since some 15% of the 'normal' population have normal patterns. Even so, several studies have shown at E.E.G abnormalities are least common in groups ghly selected for fitness (such as R.A.F pilots) and r commoner in overt neurotics while they are most mmon in groups with known organic disease of the rvous system Attempts to correlate specific person lity patterns with specific E.E.G changes have proved rewarding A passive type of personality seems to be sociated particularly with alpha rhythm, and obsessive mpulsive features with paroxysmal dysrhythmia but his is of little diagnostic help in individual cases. The cords of psychotics are no more specific The one roup of patients with a characteristic E.E.G pattern re the aggressive psychopaths. Among children with haviour disorder E.E.G abnormality is even more usual han in adults with abnormal psychological traits.

Kennard concludes that the fluctuations of E.E.G attern may coincide with several different clinical ppearances on the one hand and with any one of several ifferent chemical or physical factors on the other No e factor has been shown to be of paramount importance, or is there any indication that the physical change is sponsible for the psychological change or vice versa ince E.E.G abnormality is commoner in people with sychological abnormality than in others its diagnostic alue may increase as methods become more refined ll that can be said at present is that instability of ersonality may be associated with instability of E.E.G pattern and the most obviously relevant E.E.G abnormality is a lowered threshold to environmental stimuli. This instability may arise from hereditary factors, changes in the structure or chemistry of the nervous system and possibly (and here is the difficulty) psychological factors.'

AUREOMYCIN IN THE PREVENTION OF RHEUMATIC FEVER

THREE out of every four children who are recovering from first attacks of rheumatic fever and who are subsequently untreated may be expected to have further attacks.[1] This recurrence rate is significantly reduced, however, if they are protected against respiratory infections with group A hæmolytic streptococci by effective and continuous chemoprophylaxis[2] The recommendations[3] of the American Heart Association's council suggest that for this purpose the drug of choice at present is sulphadiazine With daily doses of 0 5–1·0 g, given over long periods, toxic reactions are infrequent and usually slight, and a great deal of evidence is now available to show that this regimen may reduce the incidence of recurrent rheumatic attacks by as much as 90%[4] *If such a prophylactic scheme were widely applied* to those at risk in this country we could reasonably expect a considerable reduction in the number of cases of rheumatic fever But the occasional serious toxic effects of sulphadiazine and (perhaps more important) the emergence of significant numbers of resistant strains of streptococci must modify enthusiasm for the method

Penicillin, when wisely used against streptococcal sore throats, is of proved value in preventing rheumatic sequelæ[5] but evidence of its usefulness as a continuous prophylactic against incidental streptococcal infections is less convincing For this purpose, either oral or very long-acting parenteral preparations are essential, and, so far we have had insufficient experience of these kinds of penicillin to allow full assessment of their prophylactic value. Among the other antibiotics, aureomycin seems to be a possible alternative. McVay and Sprunt,[6] who have already used aureomycin continuously for long periods in patients with chronic infections have now given it a trial in the prophylaxis of rheumatic fever and they report favourably on the results. In their small series which consisted mainly of young rheumatic Negroes, observed over a period of nine months, the treated group received 500 mg of aureomycin daily No serious toxic effects were noted, and liver function tests *and bone marrow examinations were normal throughout.* The absence of gastro intestinal symptoms was attributed to the inclusion of the methyl and propyl esters of *p*-aminobenzoic acid in the aureomycin preparation—an addition which is said to discourage the development of moniliasis.[7] There was a significant reduction in respiratory infections and a lower recurrence rate in treated as compared with untreated patients

A comparison of the group A strains isolated serially from a group of non rheumatic patients receiving aureomycin with the strains from a control group showed no increase in the number of strains acquiring enhanced resistance to aureomycin This finding is perhaps less relevant than a consideration of the frequency of resistant strains in the general environment Strains relatively resistant to aureomycin certainly occur and may well become as common as sulphadiazine resistant strains.

Penicillin-resistant strains, however, are undoubtedly very rare, and this fact favours the further investigation of oral penicillin, rather than the expensive aureomycin, as an alternative to sulphadiazine

The results of McVay and Sprunt, therefore, do not suggest that, in the prophylaxis of rheumatic fever, aureomycin is likely to be superior to other bacteriostatic drugs, but it is probably an effective substitute in patients who are *intolerant to sulphadiazine or penicillin*

VISITING CHILDREN IN HOSPITAL

EMOTIONAL disturbances in children—bedwetting, temper tantrums, delinquency, and the like—date surprisingly often from a period in hospital, and there is good evidence that such disturbances are the outcome not of anything that happened to them in the wards, but of separation from the mother This evidence is so telling that in March of this year the Ministry of Health strongly urged all hospitals to allow daily visiting of children by their parents They were moved to take this step by the discovery that, in 1952, only 300 out of 1300 hospitals in the country which admit children allowed daily visiting, and that 150 prohibited it altogether[1] It is to be hoped that the figures are now very different, but it is disquieting to learn[2] that one management committee at least has rejected by 16 votes to 4 a resolution to introduce the daily visiting of children in hospitals in its group The chairman, who held that the committee should be guided by the strong request of the Ministry, noted at the outset that, though matrons collectively support daily visiting, doctors are collectively opposed to it Whether or not this generalisation holds elsewhere, it was certainly true at the meeting where the vote was taken No fewer than five doctors spoke against the resolution, most of them basing their objections on the sort of personal impressions which investigation has shown to be misleading Thus the experience of one had led him to believe that the daily visiting of children is not a good thing, he had seen, he said, too many emotional upsets in the ward and the outpatient department Another, who thought that the mother with a large family at home would find daily visiting a nightmare, was at once answered by a woman member of the committee such a mother, she said, can usually find someone to look after the family while she is away, and she added a simple statement of a complex psychological truth "If a child does not see its parents it grows away from them" Another doctor mistakenly argued that daily visiting is more for the sake of the parent than the child A fourth, who had been dumbfounded, he said, by the expressions of joy and happiness of children in hospital, had evidently been deceived by the superficial unconcern and cheerfulness which have misled so many The fifth doctor raised the practical objection that children of parents living near the hospital would be visited more often than those whose parents came from a distance, and that these latter would therefore feel neglected But if some must be deprived by circumstance, does it follow that the rest should be deprived by a hospital rule? That is an argument that could have some very odd conclusions

Some years ago we reported Miss Anna Freud[3] as saying in a memorable speech about the effect of hospital on the child

> "He lives from day to day, he depends on the evidence of his senses, and his understanding of the situation is fragmentary at best A loving mother who remains absent is a figure whom he is incapable of conceiving his own love demands the nearness of the beloved person, and if she withholds herself he lacks the only proof of love which he knows and can understand. His outward calm hides dejection and a feeling of having been abandoned by those he cares most about, he becomes inwardly apathetic, though capable of interest and animation on the surface. His roots in home are dying for lack of nourishment, and he is learning to do without them, at the expense of his normal emotional life and growth"

The child who is cheerful and unconcerned in hospital, and who takes his mother's coming and going without apparent perturbation, may be storing up trouble which becomes apparent only when he gets home The child who is disturbed by her visits and shrieks at her departure is in a far more healthy psychological state For such a child—or indeed for any child, as one member of the hospital management committee pointed out—the parting will be eased if he knows his mother will be back next day

It is interesting that another member of the committee, a woman, supported the chairman in his view that matrons—and nurses too, she said, as well as mothers and other women—are in favour of daily visiting At *one time some doctors held that the nursing staff would* never agree to daily visiting, but this, it seems, was probably a misplaced fear Having the child's ultimate *well-being in mind, they are ready to tolerate the tears*

THE CASE OF THE COUNTERFEIT JAW

IN the history of field anthropology there are a number of awkward discoveries which appear to fit nowhere into any coherent scheme of the relationships of man Prominent among these is the skull found some forty years ago at Piltdown in Sussex—a skull in which cranial fragments relatively modern in form appeared to be combined with a primitive mandible and dentition So peculiar was this combination felt to be that most anthropologists reserved judgment Evolution is not a tidy subject However, the lapse of time since the discovery of the skull has brought with it new methods of estimating the age of such specimens, and thus the chance of obtaining new information about the Piltdown fragments By a combination of fluorine analysis and estimation of the nitrogen-content Weiner, Oakley, and Le Gros Clark[1] claim to have shown that the mandible and teeth of the Piltdown discoveries are relatively modern, and cannot possibly be contemporary with the cranium But there is more than this Analysis has shown that the iron staining of the jaw, in contrast to that of the cranium, is only superficial, and that the coating on the canine tooth is a thin layer of "paint-like substance" It has also been shown experimentally that the morphology of the Piltdown teeth can be closely reproduced by artificially abrading the teeth of a chimpanzee

The suggestion is made, in round terms, that the mandible and teeth are part of a deliberate anthropological fake designed to mislead expert opinion. The evidence has not yet been discussed in full, but the preliminary report is damning enough If the skull is a fake, it has been a successful one From the pages of nearly every elementary book on our forefathers there peers a truculent hairy creature bearing the legend Piltdown Man The suggestion that there never was such a creature will be accepted by most authorities with something akin to relief The layman may even be tempted to say that the anthropologists have only themselves to blame In this branch of science the facts are scanty a tooth, a fragmented limb bone, a battered skull bone—meagre enough they are for the far reaching conclusions sometimes based upon them Yet it is only by the interpretation of such clues that we can expect the anthropological study of the ancestry of man to advance, and till now we would have been unreasonable to demand that anthropologists should always suspect every discovery of being an expert forgery

THE MOTHERS' AID (MØDREHJÆLPEN) INSTITUTIONS OF DENMARK

PREGNANCY: ABORTION ADOPTION

J D B Andrews
M.D Lond. D.P.H.
FORMERLY DANISH GOVERNMENT SCHOLAR STUDYING SOCIAL MEDICAL INSTITUTIONS

THE objects of the Danish Modrehjælpen (mothers' aid) institutions, as set out in the Act of 1939 are to provide for pregnant women and mothers with children, personal, social and legal assistance, advice and guidance during pregnancy and after confinement, and help with the support of the expected child. In addition, the Modrehjælpens are playing an increasing role both in the arrangement of adoptions and in giving general educational advice on motherhood, child care, and hygiene.

The seven Modrehjælpen institutions set up in 1939 are independent of each other but work in liaison. The Copenhagen institution, in particular offers advice to the others when asked. The cost is covered partly by the State and the county and borough councils, and partly by donations from private societies and individuals.

The councils of management consist of representatives of the State, local authorities, and private associations whose objects are in line with those of the Modrehjælpen. There is also a central Maternity Aid Joint Council which watches developments in the work of the various institutions and recommends to the Social Ministry such additional measures as may be necessary from time to time. All except one of the Modrehjælpen institutions have branches run by permanent staffs; thus many of the major towns in Denmark have their own full-time functioning Modrehjælpen.

The staff of the Modrehjælpen institutions consist essentially of

The head of the institution (generally a social worker or law graduate).

University graduates in law or sometimes economics.

Social workers who have had 2-3 years training at the Social School in Copenhagen.

Gynæcologists (one of whom often acts as physician to the Modrehjælpen).

Psychiatrists.

Clerical staff.

In their day-to-day work the Modrehjælpens give: social economic *and personal aid*; *legal aid*; advice on the possibility of obtaining a legal abortion and the special help available if permission for this is refused; family advice (in Copenhagen only); educational aid; and medical aid. They also arrange adoptions.

Social Economic and Personal Aid

The Modrehjælpen enables the mother to go through her pregnancy, confinement and early years of motherhood with a minimum amount of physical, social, and psychic stress to her and to her child. Cash gifts and loans are seldom given; the women receive the actual articles they are in need of, which helps them to realise that the social worker is taking a practical interest in their problems. Many towns have arranged for the distribution of free milk through the Modrehjælpen, and this makes it possible to keep in touch with most of the pregnant women in a particular area (about 87% in Copenhagen).

The doctor or midwife delivering an unmarried mother must inform the Modrehjælpen so that a social worker can visit her and find out if she is in any special need of help. In practice most unmarried mothers visit the Modrehjælpen of their own accord, before the child is born.

All unmarried pregnant women are entitled, after the birth, to free accommodation for themselves and their infants for a year if they want it. If there is no suitable home for them in the district, arrangements are often made for them to stay at a *private house—in many cases the home of a midwife.* The Modrehjælpen institutions also run homes for expectant mothers, as well as homes taking both expectant mothers and mothers with young children. They will also find mothers posts in private houses, where they can do domestic work both before and after their confinements, so remaining financially independent. Convalescent homes (mainly open in the summer) are maintained, where mothers with young children (generally under the age of 7) can stay for a week or a fortnight on production of a doctor's certificate saying it is necessary for their health. Again there are infant homes (for children under 2 years) which provide for infants waiting to be adopted or to be sent to foster homes found by the Modrehjælpen, as well as for infants whose mothers are unable to look after them temporarily but hope, in a year or so, to be in a position to do so.

Free milk is allowed to pregnant women (0·5 litre daily for 6 months before and 1 litre daily for 6 months after the birth). Where the home is very poor, Modrehjælpen sometimes adds to the furnishings or equipment. It also provides baby clothes for the child till it is 1 year old. Domestic help is arranged for the mother in her home both before and after the confinement; but this home-help service is mainly reserved for women who have unsuccessfully sought a legal abortion.

Legal Aid

PATERNITY

It is both the duty and the right of the mother of an illegitimate child to state who the father is; but even if the father admits paternity, the facts must be legally established. The Modrehjælpen gives the woman both legal and general advice on this subject.

There are about 2000 paternity cases at the Modrehjælpen in Copenhagen every year, and in at least half of these the father acknowledges paternity at once. In the remainder there is generally some obstacle or other to the establishment of paternity. In many cases the mother is both ignorant and frightened, and it helps her if one of the Modrehjælpen's legal assistants accompanies her to the law-court. In perhaps 150 cases yearly no clear decision is arrived at in the lower court. (In these cases, the father may have to contribute to the child's maintenance, but is not named the father.) Here the Modrehjælpen is sometimes able to find new evidence and fresh proceedings can be started. The court, in fact, often seeks the Modrehjælpen's assistance in solving difficult cases.

Once paternity has been established the illegitimate child has the same legal rights as if he were born in wedlock (in regard to such things as surname, inheritance). In addition, the father has to contribute towards the child's maintenance. If two or more men are putative fathers each of them has to pay the total amount, but the mother receives only one man's contribution. This sum is three-fifths of the cost of maintenance of a child boarded out as a foster child in a good home. The money payments are generally handed over to the local authorities and they in turn hand over the money to the mother. The Modrehjælpen often advances the money direct to the mother while the case is proceeding. This sometimes takes 3–4 months from start to finish. If a man accused of paternity wishes to have blood group tests carried out on himself and on the mother and child, the judge almost always agrees and accepts the specialist's opinion on the subject.

ABORTION

The legal personnel of the Modrehjælpen also give help in abortion cases of certain types.

Application can be made for a legal abortion on ethical grounds in a pregnancy which has resulted from an incestuous liaison. In such cases the law allows the paternity to remain unestablished. In a pregnancy resulting from a case of alleged violence or rape, or through excessive influence on the man's part, the woman must inform the police immediately after the incident if she wants legal abortion on ethical grounds to be considered In these cases the police work in coördination with the Mødrehjælpen Legal abortion is also permissible where a child under the age of 15 has conceived

If a girl under the age of 21 applies for a legal abortion, the legal guardian (usually a parent) must be informed. However, if the girl does not wish her parents to be informed she can apply for a trustee to act in the place of her guardian. In many cases a legally trained member of the Mødrehjælpen acts in this capacity

In Denmark a woman may have a legal abortion for one of the following reasons

A.—Medical Indications

(1) Where this is the only means of avoiding grave danger to her life or health (somatic or psychiatric)

(2) If the *medical* danger is not conditioned by sickness, but by social conditions (e g , exhaustion) a legal abortion can be granted under certain conditions (see below)

B.—Ethical Indication

When conception is the result of rape, violence, incest, &c , or conception has taken place under the age of 15

C.—Eugenic Indication

Where there is gave danger that because of hereditary predispositions the child will suffer from insanity, mental deficiency, other grave mental aberrations, epilepsy, or serious and incurable bodily disease

Before an abortion is considered by the Mødrehjælpen in category A(2) the woman is told by the Social Worker of the various ways in which her pregnancy, confinement, and period after the birth can be eased socially and economically, and she has to be informed of the danger to herself in having a legal abortion (as well, of course, as of having an illegal abortion) However, before it is decided whether a legal abortion will be advised on account of *any* of the above indications, the following procedure is carried out

In the case of a somatic medical indication being suggested, the woman is seen by a specialist in the particular field concerned if necessary, or is admitted to hospital for observation. In the case of a psychiatric indication the woman has a thorough psychiatric examination from one of the Mødrehjælpen's psychiatrists, and also, if necessary, is admitted to hospital for observation

In the case of an ethical indication the police have to be informed , and where rape is alleged the police interview and question the woman in detail Where the indication is eugenic the Institute for Human Genetics inquires into the personal and family history This institute has records of a very large proportion of the hereditarily tainted families in Denmark, including details of their admittance to hospitals or mental institutions, and the diagnoses made The institute sends a report to the Mødrehjælpen A " conditional " indication for abortion is said to be present when there are medical or ethical arguments in favour of a therapeutic abortion, and in addition there is a slight possibility of inheritance of disease Naturally it is generally impossible to give a percentage probability of a hereditary disease occurring in the offspring Legally, the case of a eugenic indication is treated separately from the question of sterilisation

In 1950, there were 702 applications to the Institute for Human Genetics for a legal abortion on genetical grounds , 626 of them came through the Mødrehjælpen, and 254 of these were granted, 279 were " conditionally " granted, and 93 were refused In addition there were 87 applications for legal abortion plus sterilisation, 71 coming from the Mødrehjælpen, of which 48 were granted, 21 granted " conditionally," and 2 refused

Procedure

The woman coming to the Mødrehjælpen seeking an abortion is generally referred there by her own doctor, but she can come direct if she likes Doctors are compelled by law to refer all women who come to them seeking abortion other than abortion for strictly medical [illegible] to a Mødrehjælpen

A social worker sees the woman, either at the Mødrehjælpen or in her own home, and takes a full social and medical history She confirms some of these details from the records of the child welfare committee, and the social offices, and often has an interview with the husband or other near relative. The case is then reported to the gynæcologist, who gives her a thorough general, obstetric, and gynæcological examination, and if necessary refers her to the psychiatrist A case-conference follows (in Copenhagen), and, if a legal abortion is thought necessary, the woman is referred to a surgical department of a hospital Before the operation is carried out two doctors have to give their consent , and in practice these are the surgeon undertaking the operation and the physician or psychiatrist attached to the Mødrehjælpen About a third of all women coming to the Mødrehjælpen (excluding those coming for free milk) are seeking legal abortions and, if the Mødrehjælpen decides that abortion is indicated, a full statement of reasons, with the case-history, is sent to the surgical department of the general hospital in which she will have the operation. Details of every case have also to be sent to the Medical Council after the operation has been done

Special Help

In 1948–49, 2321 women sought legal abortions in Copenhagen, and permission was given to 897, of whom 12 sought further help Of the 1424 refused permission, 265 sought further help from the Mødrehjælpen They are naturally entitled to all the usual help given by the Mødrehjælpen as well as the special help set aside for women who have been refused a legal abortion. This is specially designed to make their pregnancy, labour, and puerperium easier, and to provide better conditions for the child

In 1948–49 the Mødrehjælpen spent the equivalent of £1339 on furniture and equipment for the homes of patients, £435 in compensation for loss of work (mainly to unmarried mothers), £234 on other maternal expenses (clothing, rent, cash grants, and payments for the child in an infant home), £210 on mothers' debts and hire purchase instalments, £162 on home helps, and £161 on baby clothes and other equipment for the child (such as prams and cots)

The Mødrehjælpen also sometimes helps in training the mother in a trade (such as sewing), so that she may be able better to support herself and the child

Family Advice

About a third of the mothers seeking abortion give as their main motive family or personal conflicts In 1949 a family advice department was set up in association with the Copenhagen Mødrehjælpen, financed by the Social Ministry, where patients and their families could seek further social, psychiatric, and medical help

The staff consists of a psychiatrist, a psychologist, and three or four social workers They hold their sessions in the evenings so as to have a better chance of seeing several members of the family The social workers often interview the women in their own homes, and thus have a better opportunity to meet the father, who is sometimes unwilling to go out to a consultation But an effort is made in every case to see both wife and husband, as well as other members of the family concerned in the particular family problem (especially adolescent children, or the parents of the husband or wife) Patients are referred from a variety of sources—the school psychological services, psychiatric departments of hospitals (who send patients requiring aftercare), and general practitioners. In addition, some patients attend of their own accord. Many are referred from the Mødrehjælpen when permission has been refused for a legal abortion Results are often better where the patients have come directly from one or other of the Mødrehjælpen departments, as friendly relations have already been established. This also makes it possible to weed out apparently hopeless cases and so save the staff's valuable time

Most of the patients are married, some are engaged couples, or people living together, or single people with special sexual problems Most of them are in the younger age groups A very large number of patients relate their sent family problems directly to bad housing con ions. The main types of case seen by the family vice departments are

Women complaining of neglectful husbands, some of whom good husbands except for their addiction to alcohol
People seeking sexual education
Families in which one member at least has a neurosis or is ychopathic
Families whose external difficulties seem to be the main use of unhappiness (e.g the single mother with her child, ing in very poor conditions);
Sexual problems or unfaithfulness
Problems with adopted children.

Many of the patients need a combination of social, ychiatric, and medical help No deep psychotherapy is dertaken, but the patients are helped to adapt them lves better to their marriage partners and their rroundings. Group therapy is arranged once a fortnight der the direction of a psychologist and has helped eatly in giving patients social contacts A complete ck of friends and acquaintances has been very noticeable nong those seeking help from the family advice epartment.

Complete cures have been few but in well over half e cases the difficulties have been lightened and the milies have been better able to carry on In about a uarter the conditions remained the same but these atients were still being given help by the department ontact has been lost with most of the remainder except r a very few in which conditions worsened This evelopment, however was not unexpected in the cases question Separation or divorce was not as a rule dvised, though legal aid to these ends was given when t was sought.

Adoption

Adoption in Denmark is of two kinds

1 Where the parties to the adoption are acquainted and the mother of the child has access to the child (perhaps a quarter to half of all adoptions) In these cases, the adopting parents are often relatives of the mother

2. Where the adopters or the mother want a special clause inserted saying that the mother must not be allowed to see the child. In these cases the mother and the adopters are not acquainted (some half to three-quarters of all cases) In these cases the adoption must be handled by a body or person holding a special licence from the Ministry of Justice. The Modrehjælpen institutions, a few leading doctors, the heads of children's homes, and child welfare committees have hitherto held this licence but recently it has been decided that in future licences *will only be issued to* the Modrehjælpen institutions. At present probably about 80–90% of the adoptions with this clause in it have been arranged through the Modrehjælpen. In 1948–49 there was a total of 1052 adoptions.

A central department in Copenhagen now supervises all adoptions. This arrangement has given the Modrehjælpens wider choice of prospective adopters. The inter viewing of both the mother and the prospective adopters is done by the local Modrehjælpen As in other countries, there are more supposedly infertile couples wishing to adopt children than there are children free to be adopted so it is possible to choose the adopters carefully There are about three would be adopters for every child available, and many more wish to adopt girls than boys The waiting time at the moment is about 1–2 years The Modrehjælpen tries to place the children as soon as possible after they reach the minimum age (3 months) at which they can be legally adopted If the woman wants to have her child adopted, she does not as a rule breast-feed him or her unless the hospital where she is delivered makes breast-feeding a rule

The mother has the right to free accommodation for herself and her child at a mother-and-children's home for a year after the birth The Modrehjælpen makes sure as far as possible that the child is not being offered for adoption for financial reasons alone; if the mother needs help outside the scope of the Modrehjælpen she can get it from the child welfare committee Where adoption is decided on the social worker takes a full case history and asks about the father of the child—if possible interviewing the father as well. If there is any reason to think that there is some hereditary taint on either side, the Genetical Institute is consulted on the advisability of adoption

In 1950 out of 260 inquiries from the whole country the Genetical Institute reported that adoption was not contra-indicated in 162 cases, was indicated with reservations in 90 and was contra indicated in 6 In 2 cases no answer was made The Genetical Institute are often asked to say whether it is necessary to tell future adopters about the possibility of the child displaying some hereditary taint If the possibility is remote and will only worry the adopters, the Modrehjælpen usually favours silence

The social worker who sees the mother after the birth sees her again before the adoption takes place (at least 3 months later) to make sure she still wishes the adoption to take place

The physical condition of the child, and his mental growth and development is studied in a children's home. The mother can thus, if she wishes, take her child back without the prospective adopters being distressed—as they would be if the child was already living with them Where the advisability of adoption is doubtful it is often found wise to keep the child in the home for a year or more in order to assess its probable development.

The social worker at the Modrehjælpen, at her first interview with the adopters, asks them whether they have been to a doctor to have the cause of their supposed infertility investigated, and if they have not advises them to do so She then tells them of the legal and moral duties and rights of adopters.

Generally speaking the adoptive parents must be a married couple not under 25 years nor over 55 not suffering from any infectious disease and possessing some financial security They must have a certificate from the child welfare committee saying that they are considered suitable to adopt a child. The social worker asks whether the adopters have been in conflict with the law during the last 20 years; she receives information about their capital and income and interviews two people who have known the couple for many years she may also get a statement from a doctor or someone else who has known the couple intimately about the success or otherwise of their marriage their interest in children, and their motive for wishing to adopt. Lastly she visits their home and assesses its suitability

A conference on all the collected information about the child his or her parents and the prospective adopters, is held in the central department in Copenhagen The child's interests are regarded as absolutely paramount in deciding whether the adoption shall go through

Before adoption is completed the police interview both the mother and the adopting parents, and the case is then referred in most cases to the head of the county council If there are complications the papers are sent to the Ministry of Justice before being finally approved or rejected.

When choosing the parents, the Modrehjælpen takes various other factors into account thus, if the adoptive parents are living in a different locality from the mother she is less likely to see or hear of the child Then the Modrehjælpen tries as far as possible to place the child with people of similar intellectual capabilities and from the same milieu as its parents though naturally children coming from very poor homes are placed in better and more secure economic circumstances. Height, bodily habitus, and colour are taken into account so that there is some likelihood that tall people will adopt tall children &c

If the adoptive parents die or in the very rare cases where an attempt is made to annul an adoption order (for instance because the child proves to be oligophrenic) the legal advisers help to arrange a new adoption, or in the latter case advise the adoptive parents.

Medical Aid

The pregnant woman can be examined by a gynæcologist at the Mødrehjælpen, to confirm that she is pregnant, and she is also seen at least 3 times by the Mødrehjælpen doctor, and 3 times by the midwife during the pregnancy, and more often if necessary If she has any somatic disease likely to be adversely affected by pregnancy she is referred to a specialist and if necessary admitted to hospital Under the Pregnancy Hygiene Act, 1946, however, these duties now fall on general practitioners, as part of their service to members of the various health insurance societies

Educational Aid

Advice on health is given by the gynæcologist and the midwife when the woman first attends the Mødrehjælpen to have her pregnancy confirmed, and courses of lectures are arranged on various subjects such as hygiene of pregnancy, the proper nourishment of children, and child psychology. Classes in sewing and cutting are also held

General sexual education as well as instruction in methods of contraception, are undertaken by a woman gynæcologist

Research

Since 1947 a psychiatrist and 2 social workers have been following up 500 women who came to the Copenhagen Mødrehjælpen in 1943 seeking abortion The main aim of the research is to find out the long term results achieved by the three possible end-results

1. The woman proceeded to term (and either kept her child or had it adopted)
2. A legal abortion was advised
3. A "spontaneous" abortion took place (in many cases presumably due to illegal interference)

The practical difficulties of this social and psychiatric follow-up are great because the woman has often married, married again, or is living with parents who know little or nothing about the incident in question Much tact is needed

The Future

It is widely thought that the Mødrehjælpen should become a social institution used by the population as a whole, and not only by a particular section of it The free milk given to pregnant mothers is helping towards this goal as it is largely arranged through the Mødrehjælpen

Social and economic aid for women who have sought a legal abortion is provided from public funds, but the amount of private money available to help other pregnant women seeking help is very small indeed Flats are badly needed for single mothers with children (such as those provided in Sweden) where they can bring up their children in secure and homelike surroundings, one apartment house with 54 apartments has recently been opened in Copenhagen Educational establishments are needed where mothers (especially those who are single) can learn a skilled job, and so be able to support their child adequately More nursery schools would be welcome both for the children of mothers who have to go out to work, and for those of some mothers who are equally busy in the home Many think a law should be introduced forbidding employers to dismiss any woman on account of pregnancy (a law of this kind has been in force for a long time in factories) The loss of wages incurred by the women would be paid for out of public funds, so that employers would not have to bear the loss

The Mødrehjælpen institutions are only dealing with the fringe of the abortion problem More individual personal help and advice are obviously needed by women asking for an abortion Recent research carried out on women being admitted to two big hospitals in Copenhagen for the immediate after effects of an abortion showed that only 1–2% had previously applied to the Mødrehjælpen for a legal abortion A suggestion, successfully opposed in 1939, that there should be a social indication distinct from the medical indication for legal abortion is now being made again

Further development of the Mødrehjælpen institutions depends largely on whether sufficient public and private funds can be found to meet the growing scope of such an organisation, and whether interest in the institutions can be fostered among such people as doctors and lawyers, who are able to call public attention to the value of these centres and the need for their extension

Summary

The scope of the Mothers' Aid Institutions of Denmark is described They cover the whole of Denmark

The organisation gives medical, social, and legal help and advice to pregnant women and mothers with young children The daily work includes social, economic, and personal aid, legal aid, advice with regard to the possibility of obtaining a legal abortion, family advice, adoption arrangements, and educational aid

The institutions wish to become an agency for pregnant women and women with young children in general, and not only for those in social or economic distress. The social workers are the mainstay of the institutions, but in addition there are gynæcologists, psychologists, and lawyers attached to them

Probably the greatest advantage of the institutions is the comprehensiveness of the social aid they give. In other countries which have similar social welfare services the organisations concerned, both statutory and voluntary, are often widely dispersed

I would like to express special thanks to Fru Vera Skalts, head of the Copenhagen Mødrehjælpen, and Dr Henrik Hoffmeyer, psychiatrist attached to the institution, for the help they gave me while studying at the institutions in Denmark, and also to Fru Eva Knudsen for her help and kindness in the preparation of this article

---

RECENT ADVANCES IN THE PROTEIN *FIELD*

THE nutrition panel of the Society of Chemical Industry held in London on *Oct* 28 the first of a series of meetings devoted to Nutritional Reappraisals. Mr A E BENDER, PH.D, discussed Proteins. He dealt particularly with two topics—the biosynthesis of the peptide bond, and protein nutrition

Our earlier views on the static nature of protein katabolism, defined nearly fifty years ago by Folin, were revolutionised by the work of Schoenheimer and Rittenberg using isotopically labelled amino acids. Whereas we used to believe that protein synthesis came to an end at maturity we now know that it continues even in the adult We picture a small but rapidly metabolising amino-acid pool, fed from the dietary proteins and in equilibrium with the structural and functional proteins of the body While single amino acids and incomplete mixtures can enter the pool and participate in the various equilibria, as indicated by the rapid entry of labelled amino acids into tissues, they cannot remain in the pool and they, or their equivalents, are immediately excreted

The amino acid pool is turning over at great speed; the half life period of human protein is 80 days, that of the liver and serum-proteins is 10 days, and that of the carcase 158 days Rittenberg has calculated that the pool consists of 0 5 g nitrogen per kg body weight, and that protein is synthesised at the rate of 1 3 g per kg per day, or 90 g for the average adult Such rapid and continuous breakdown and resynthesis of protein emphasises the question of how the peptide bond is synthesised One fundamental fact has been clearly established—that the synthesis of a dipeptide from two amino acids requires the intervention of the energy rich phosphate bond Many isolated tissues will take up labelled amino acids and the process can be inhibited by reagents which are known to stop phosphorylation After the synthesis of the dipeptide several possibilities exist. One is the stepwise addition of further amino acids under the influence of proteolytic enzymes, such as chymotrypsin, resulting in a lengthening of the peptide chain. A second method involves the transpeptidation reaction catalysed by cathepsin. In this process the first step is the synthesis of the two amides—glutamine and asparagine—and the tripeptide glutathione which requires a supply of energy These compounds then exchange a group with the peptide chain without any further expenditure of energy resulting in a lengthening of the peptide chain These methods have been shown to work in vitro, but we do not yet know whether they are the actual methods involved in vivo A quite different procedure has been postulated by Dounce who suggests that the nucleic acids act as templates governing the order of arrangement of amino-acids in the polypeptide chains. Dr Bender suggested that these findings hold great promise for the speedy answer to the problem of protein synthesis.

With regard to protein nutrition he said that recognition of the need to be able to express the nutritive value of the different proteins rather than to think of all proteins as being equal has been slow in spreading from the laboratory to the fields of practical application There are still many medical men who regard all proteins as one substance and do not appear to be aware of their differing nutritive values.

The biological measurement of the nutritive value of a protein is a long and relatively inaccurate procedure and a valuable contribution has been the demonstration that the percentage of the limiting essential amino acid present as compared with egg protein—i e the so called chemical score—is closely correlated with the biological value. This correlation appeared to hold despite the recent evidence that the amino-acid make-up of a protein is not the only factor involved. For example it has been shown that amino-acids may be present in a protein but not liberated during digestion and are therefore unavailable. This is of particular importance in the case of cooked and stored proteins where lysine combines with sugars and cannot be liberated by enzymatic attack. Another difference is in the site and rate of liberation of the constituent amino acids which also affect their availability

It has been shown that for protein synthesis all the essential amino-acids must be presented simultaneously to the cell synthesising mechanism: there is no storage For example, if five of the essential amino acids are fed at one meal and the remainder twelve hours later the animal dies of protein starvation Hence the rate of release of amino acids during digestion is a factor of some importance, and it has been shown that different proteins release their amino acids at different rates Thus it should be possible to have two proteins of identical chemical composition but differing considerably in nutritive value. Despite this, biological value has been shown to correlate with chemical composition

The immense practical value of being able to predict biological value from chemical composition has made re-examination of the position worth while. Analytical and biological data suggest that there is a different relation between the content of the limiting essential amino-acid in a protein and its biological value from that originally postulated by Mitchell and Block in 1946 A protein completely lacking one essential amino acid —i.e., with a chemical score of zero—has a biological value of zero A protein containing its full complement of amino-acids (that is having a chemical score of 100) is completely utilised thus having a biological value of 100 From this relationship Dr Bender suggested that each chemical score should correspond numerically with the biological value

That the revised chemical scores accord with this theoretical relationship only approximately is due to the low standard of accuracy at present attainable in amino acid estimations, as was demonstrated in the recent coöperative test organised by the Rutger's Bureau of Research. Better methods of amino-acid estimation together with further applications of the revised chemical score method, might lead to a wider use of actual nutritive value rather than the non specific description of proteins merely as proteins. Mr E M **Learmonth** discussed the abnormal proteins observed in the blood plasma of infants receiving deficient diets In the absence of the essential amino acid lysine plasma-proteins have appeared in which the lysine is replaced by non essential arginine. Such changes may be involved in the evolutionary processes.

Mr K J **Carpenter**, PH.D said that, despite the poor agreement between different laboratories in the Rutger's Bureau coöperative assay of amino acids in proteins, the results have been of considerable value and microbiological assay has provided useful information He asked whether biological value is an important factor in diets where a surplus of protein is consumed Dr **Bender** replied that, while it is not significant in Western diets, it is important where the diet contains minimal amounts of protein

---

FELLOWSHIP FOR FREEDOM IN MEDICINE

Fear that a full time salaried health service is a real possibility was expressed at the annual general meeting of the Fellowship for Freedom in Medicine on Nov 21 at which Lord **Horder** presided The meeting reaffirmed the demand that private patients should be entitled to drugs under the same conditions as National Health Service patients, their doctors submitting to the same control in respect of prescribing as those in the service

Dr E C **Warner** (hon. secretary) reported that the medical and dental members of the Fellowship number 2530 compared with 3081 a year ago Those who left after the Danckwerts Award forgot that it was the Fellowship which had rescued arbitration from the wastepaper basket and insisted that it should again become the policy of the British Medical Association In the last few months there had been an increase in membership following the stand taken at the B M.A. Representative Meeting on the restoration of good will and the determination to resist a whole-time salaried service Speaking of the success of the Fellowship's pamphlet for doctors on the rights of the private patient under the N H S Dr Warner said that another leaflet was being prepared which could be handed to patients. Dr Warner emphasised that the Fellowship is not opposed to the B M A. as such. It had been able to make its voice effective in the councils of the association.

Dr G J V **Crosby** presenting the report of the general practitioner hospitals subcommittee, said that the general practitioner hospital is far more economical than the health centre General practitioners were being asked in some places to take on work from which they were excluded in 1948 and this again was a source of considerable economy

Dr J O M **Rees** secretary of the subcommittee on private practice called on the Fellowship to make drugs for private patients its target for the year

The meeting unanimously approved the programme of reform of the health service proposed by the Amending Acts subcommittee of the Fellowship This was presented by Dr A. C E **Breach** Asking that the possibility be examined of vesting the administration of the N H.S in an independent body composed of persons of national repute Dr Breach said that if medicine could once more be freed from politics there would be some hope The gradual, insidious onset of a salaried service was a real danger The greatest safeguard was the optional restoration of the right to buy and sell the good-will of general practices The subcommittee wanted to find ways of relating the remuneration of a doctor to the quality of his work, and not merely to the number of patients Other recommendations in the report were that there should be established under the presidency of someone of the standing of a High Court judge a permanent independent court of arbitration, that the method of constituting the local executive councils be adopted as a pattern for all other administrative committees, the relevant interests being directly represented, that regulations, orders, and "directives" should be issued only after consultations with appropriate interests, with arbitration in the event of non agreement, and that medical staff committees should be officially recognised Health centres should not be owned and controlled by local authorities and encouragement should be given to the formation of group practices by the provision of long-term, low interest loans In the interests of the public and the N H S itself, no opportunity should be lost of encouraging private practice The meeting agreed that the executive committee should act for the Fellowship when Dr Breach's subcommittee presented its further report on reform

A lay associates' committee was established, and to this was referred the question of drawing the attention of M P s to the provision of drugs for private patients

Lord HORDER, in his survey of the Fellowship's work, said that the Guillebaud Committee gave them a chance of saying once more that every time one shut out the general practitioner, one cost the patient and the country more time and money—and got less good results There was no economy without efficiency, as Disraeli remarked, and it was not efficient to eliminate the expert Lord Horder criticised B M A apathy in letting basic principles go downstream "they have ceased '*from mental fight*' We have not" It was not true that the public were in general thoroughly satisfied with the service Medicine must have freedom It must control its own career, it could not accept control from the State, least of all by party politicians He repeated what he had said ten years ago—if the nation wanted the best that medicine could give, this autonomy must be preserved against all comers

MYXOMATOSIS

THE PROTECTION OF LABORATORY RABBITS

IN response to inquiries the Laboratory Animals Bureau has issued some brief notes[1] on the steps which may be taken to protect laboratory rabbits against myxomatosis, a virus disease which has now spread from the Continent to parts of Kent and Sussex[2]

The bureau states that the infection is enzootic in certain wild South American rabbits, where it has a comparatively low mortality, but it is almost 100% fatal in European rabbits In the rare instances of natural recovery, permanent active immunity is established The disease has not been conclusively demonstrated in any other species

The virus is spread by bloodsucking insects, chiefly mosquitoes and midges, but fleas and other ectoparasites can carry it Infection may also occur by direct contact, and even human contact can convey the virus from an infected to a normal animal The incubation period is 4–5 days and death occurs from 3–10 days from the onset of symptoms The earliest symptom is blepharoconjunctivitis, followed by swelling round the nose and mouth, and a copious nasal discharge which is loaded with virus. Myxomatous swellings appear in various parts of the body, with rapid wasting and terminal pyrexia

Myxomatosis will readily spread to laboratory rabbits unless precautions are taken There is little chance of spread during the winter months, but it is very likely to flare up in the spring and summer Preparations for the protection of laboratory stocks should therefore be made without delay

(1) *Control of Vectors*—Wherever possible, vectors should be prevented from entering rabbit houses This will involve proofing windows, ventilators, and other openings against mosquitoes and midges, the provision of air lock doors, change of outer garments and footwear for those entering the rabbit house, and the use of insecticides within the house—for example, by means of aerosols To be effective, these precautions must be very thorough

(2) *Control of Cases and Contacts*—Immediate killing of cases in the early stage of blepharoconjunctivitis, burning the carcases, and disinfection of the cages, are essential precautions Contacts should be isolated for seven days Wholesale destruction of contacts, even of cage mates, is not necessary

(3) *Immunisation*—Vaccination with the Boerlarge strain of the Shope fibroma virus confers a strong immunity to myxomatosis lasting at least 12 months The vaccine is injected intradermally or subcutaneously, and immunity is established before the 14th day

If rabbits are obtained from another laboratory or from a breeder or dealer, the risk of their being infected must be accepted It would certainly be possible to arrange for the vaccination of accredited breeders' rabbits, and possibly of those of other breeders as well How far the bureau is able to help dealers will depend on the extent to which the dealers are willing to accept help and some measure of control.

An advisory committee on myxomatosis has been set up with Lord Carrington as chairman Until this has reported it is not possible to say where the vaccine is to be obtained, or what the recommended dose and vaccination technique are

GENERAL MEDICAL COUNCIL

OPENING the 187th session on Nov 24, Sir DAVID CAMPBELL, the president, paid a tribute to the work of the late Colonel Norman King, formerly registrar, who served the council from 1897 to 1933 As a new member he welcomed Mr Keith Paterson Brown, who now represents the Royal College of Surgeons of Edinburgh in place of Sir Henry Wade.

At its last session, Sir David said the council approved a method of election to the Medical Disciplinary Committee which while preserving the necessary degree of continuity in the membership will give each member of the council an opportunity to serve A similar scheme of election to the Penal Cases Committee will be proposed

Six years having passed since the publication of the current recommendations relating to the medical curriculum, the time is approaching when the council wil have to study the effects of these recommendations and consider how far it may be necessary to revise them in the light of the changing circumstances of medic practice In due course the council will be receiv reports from its visitors and inspectors, but meanwhil it will be asked to consider the desirability of hold a debate next May on the whole question of medi education, including the impact thereon of the co pulsory period of house-officer appointments

The council published last year a list of the hospitals Great Britain and Ireland and of the posts therein approv for the time being by licensing bodies for the purpose of hou officer service under the Act of 1950 That list included hospitals and 3048 posts Since then, the council has b informed that 53 other hospitals have been approved, wh 4 included in the list have ceased to be approved The numb of recognised posts has increased to 3232 A list setting o detail the changes both in the number of hospitals and posts as now been issued by the council for the guidance of all ncerned.

---

[1] Supplementary Memorandum to L.A.B News Letter no 7 (January 1954) Copies may be had from the bureau, at the Medical Research Council Laboratories, Holly Hill, London, N W 3

[2] See *Lancet*, Nov 14, 1953 p 1031

Licensing bodies are empowered to approve for this purpose ospitals not only in this country but also in the Common ealth and in foreign countries, and the council has now sued a list showing the hospitals and institutions in Colonial rritories which have been formally approved by one or ore licensing bodies for an indefinite period The list also ets out the posts which have been recognised in each hospital. he council understands that a number of licensing bodies hile not necessarily dissenting from the revised and con olidated list of hospitals and posts recommended earlier n the year by the Colonial Office intend to consider on its erits each case in which one of their graduates wishes to e employed in hospitals in Colonial territories.

After speaking with regret of the approaching retirement of Mr Frederick Winterbotham as solicitor to the council the President concluded by referring to cases in which there have been fraudulent dealings by general practitioners under the National Health Service In one case a practitioner obtained money from the local executive council by submitting forms relating to the treatment of temporary residents whom he had not in fact treated In another case a practitioner had been convicted in a court of law of fraudulently charging fees to patients who were on his N H S list.

"The Penal and the Disciplinary Committee have reason to believe that the cases in which inquiries have already been held are not the only cases in which a practitioner has wrongfully obtained sums of money from the executive council or has improperly demanded and accepted fees from patients on his National Health Service list I desire therefore to take this opportunity of bringing to the notice of the whole profession the gravity of offences of this nature A conviction in such a case inevitably brings an offender within the disciplinary jurisdiction of the council; and in instances where no conviction has occurred it is nevertheless open to the Penal Cases Committee of the council to refer to the Disciplinary Committee for inquiry any case duly reported to them in which there appears to be a prima facie case that a practitioner has been guilty of such serious unprofessional conduct

Public Health

County of London Census Figures

The full 1951 census figures for the County of London have now been published.[1] Details for other counties in England and Wales will appear at short intervals. The total population in the area of the County of London at the 1951 census was 3 347 982, representing a net decline over the whole period since the 1931 census of over a million, most of which has occurred since 1939 The dwellings in the county, occupied by private households or vacant, now number 820 918 Since the last census in 1931 some 100 000 new permanent dwellings have been erected, nearly one-third of them since the late war Some 70,000 dwellings were totally destroyed by bombing during the war; and 30,000 new dwellings have been added since the war as a result of conversions. There has been a further reduction in the over-all density of occupation of dwellings from 0 98 persons per room in 1931 to 0 83 persons per room in 1951—largely due to the increase in the proportion of small households. The proportion of persons aged 16 and over in full time education in London was more than twice as high in 1951 as in 1921, when the question was last included in the census. Comparison of the figures for the County of London and for England and Wales suggests that, both in the younger and the older sections of the occupied population the duration of full time education has been slightly longer in London than in the country generally no doubt owing to the migration to the Metropolis of disproportionately large numbers in the higher administrative and professional occupations.

Symposium

PHENYLBUTAZONE

EMPIRE RHEUMATISM COUNCIL'S DISCUSSION

In the two years which have elapsed since the first report[1] from this country on the treatment of rheumatic diseases with phenylbutazone, a considerable fund of experience of the effects of this important drug has accumulated Its actions and dangers have been the subject of considerable controversy, and in choosing phenylbutazone as the subject of the first of a series of symposia the Empire Rheumatism Council provided a useful opportunity for an interim stocktaking As the chairman of the clinical section, Dr W S C **Copeman**, pointed out the intention of the meeting on Nov 13 was to provide objective data rather than current views and experience

Relief of Symptoms

The ability of phenylbutazone to produce subjective relief in a high proportion of cases of rheumatoid arthritis was amply confirmed. Dr O **Steinbrocker** who described his extensive observations in the U S.A had found a significant analgesic effect in about 70% of his cases and improvement in function in about 50% with very definite benefit in 23% Dr G R **Newns** (Sheffield) had compared the effects in early and advanced cases; symptoms were relieved in 70% in each group and the good response of advanced cases was confirmed by Dr F **Dudley Hart** (London) Dr J H **Jacobs** (London) had found that failure to respond tended to occur in those clinically active cases with a high erythrocyte sedimentation rate.

While there is no serious disagreement about the proportion of cases obtaining subjective relief views on the extent of objective changes are less uniform. The figures quoted at the symposium were in general agreement with earlier reports on subjective responses during the early stages of treatment and it was perhaps of more interest to hear how patients had fared during long-continued courses. In Dr Newns's series of 197 cases 65% were still taking the drug after six months; 13% had dropped out because of failure to respond ab initio 7% because the initial response had not been maintained, and 14% because of toxic effects. In a rather longer follow up of 17 cases Dr Steinbrocker had seen 8 instances of relapse or interruption of improvement by toxic complications. Dr J P **Currie** (Glasgow) reported that 82 out of 131 cases maintained on treatment for a year or more were still improving while none had failed to enjoy continued relief of symptoms. It appears, therefore that while an immediate favourable response cannot always be maintained, either because of relapse or of intolerance a useful proportion of patients can benefit from prolonged treatment

In ankylosing spondylitis Dr Steinbrocker had found a good analgesic effect from phenylbutazone Dr G D **Kersley** (Bath) commended its use in cases which had failed to respond to radiotherapy, and Dr Dudley Hart had found the drug particularly valuable in advanced cases.

Antirheumatic Action?

The important question whether or not phenylbutazone has a specific antirheumatic action was discussed by several speakers. It is not easy to lay down criteria which must be satisfied before any therapeutic agent can be credited with such an action A drug capable of exerting an anti inflammatory eff which is general, or even confined to inflammation a particular type, cannot strictly be held to be anti rheumatic, even though it may suppress all or some of the manifestations of rheumatic inflammation But a stronger case can be made out for a drug which profoundly influences the pain of rheumatic diseases, yet is not definitely effective in non rheumatic pain, and which suppresses the local and systemic signs of inflammation in these conditions The situation would be clearer if the inflammatory phenomena of diseases as clinically heterogeneous as rheumatic fever, rheumatoid arthritis, and gout could be accepted as sharing a common pathogenesis

---

[1] Currie, J P 2nd European Rheumatology Congress Communications, p 417

Prof R **DOMENJOZ** (Saarbrucken) provided evidence that phenylbutazone has a suppressive action in several types of experimentally induced inflammation in animals —though Prof G A H **BUTTLE** (London) had been less successful in demonstrating this—as well as its analgesic, antipyretic, and anti-histamine effects The anti inflammatory action was retained in adrenalectomised animals, and phenylbutazone caused no depletion of adrenal ascorbic acid in hypophysectomised animals, showing that it exerted no pituitary corticotrophin-like effect

Dr Currie pointed out that the effectiveness of phenylbutazone and of other drugs in rheumatic diseases paralleled their ability to inhibit the development of œdema after the injection of irritants in animals The anti-histamine, analgesic, and antipyretic activities of the drugs compared (antipyrin, amidopyrine, isopropyl antipyrine, and phenylbutazone) were much less closely related to their therapeutic potency in rheumatic diseases He also emphasised the low analgesic potency of phenylbutazone in normal humans and in animals, as well as in pain of non rheumatic origin—cephalgia, migraine, trigeminal neuralgia, and root pain in intervertebral disc lesions Similar poor results have been reported [2] elsewhere in intervertebral disc disease, nerve root pressure, and migraine, though good analgesic effects have been claimed in postmenopausal osteoporosis[3] Paget's disease,[4] and "neuritis and radiculitis"[5]

Variable results have been obtained in osteo arthritis [2-4] Dr J S **LAWRENCE** (Manchester) found aspirin rather better than phenylbutazone in this condition and in non articular rheumatism Dr **FRANCIS BACH** (London) had been specially impressed by the results in osteoarthritis of the hip, and Dr **PARSONS**, speaking as a general practitioner and a patient, was enthusiastic about his results, particularly in old people

Dr Currie believed that good evidence of a specific antirheumatic action was afforded by the prompt response to phenylbutazone of the fever and arthralgia of rheumatic fever, now well established,[3 4 7-9] and of the symptoms of acute gout [3 10-12]

In rheumatoid arthritis, evidence of an anti inflammatory effect is generally sought in changes in the size of swollen joints and in the erythrocyte sedimentation rate Dr Steinbrocker was dubious about any true antirheumatic activity, though he mentioned some early good results from the injection of phenylbutazone into joints Dr R I **MEANOCK** (London) and his colleagues and Dr Dudley Hart were not convinced that joint swelling was affected by the treatment, though Currie et al.[13] have claimed a definite reduction, particularly in early and acute cases, and they have suggested that divergent views on this point may arise from the varying proportion of such cases included in individual series. The majority of those at the symposium thought that the erythrocyte sedimentation rate was not influenced by phenylbutazone, though Dr Lawrence believed that a reduction sometimes occurred, and he pointed out that a concentration in the blood of 10 mg per 100 ml could retard sedimentation in vitro

C reactive protein, which rapidly disappears from the blood during the treatment of rheumatoid arthritis with cortisone or corticotrophin,[14] was not affected in 2 of 3 cases investigated by Dr A G S **HILL** and Dr M **SAXTY GOOD**, but in the 3rd a weak reaction disappeared, possibly as a result of spontaneous improvement

The present situation seems to be that an antirheumatic effect is hard to define and that the action of phenylbutazone in this regard has not been convincingly established. Certainly there is no suggestion that the drug has any curative action—relapses after stopping treatment follow as promptly and as regularly as they do after cortisone

Increase in Coagulation-time

A hitherto unrecognised effect of phenylbutazone was described by Dr J G. **HUMBLE** (London), who found that a small proportion of patients receiving the drug had a prolonged coagulation-time The investigation was prompted by Hart's observation of a fall in capillary resistance in some of his patients An isolated instance of a prolonged clotting-time has also been reported.[15] Dr Humble's inquiries led him to the conclusion that the phenomenon was due to a true deficiency of prothrombin, it could be reversed by giving vitamin K, or by stopping phenylbutazone The development of this coagulation defect was related to the daily dosage level, rather than to the duration of treatment. Dr. Humble declined to speculate on the obviously important possibility of a relation between this effect and the occasional occurrence of gastro intestinal bleeding during phenylbutazone treatment

Some Metabolic Effects

Dr R M **MASON** (London) helped to clear up the confusion which has existed about the effect of phenylbutazone on uric acid metabolism The urinary excretion of uric acid in individual cases depends on the balance between water retaining and mild uricosuric actions. In general, increased elimination of uric acid was sufficient to explain the well established lowering of plasma-uric-acid concentration This uricosuric effect, leading to urate precipitation in the urinary tract, was suspected to be the cause of oliguric death in a case of gout treated with phenylbutazone [16]

The effect of phenylbutazone on the excretion of water and electrolytes was discussed by Dr P O **WILLIAMS** (London), who considered that sodium was retained by reason of a specific increase in tubular reabsorption and that water retention was a secondary effect The output of potassium was unaltered In most individuals, the effect was not progressive and ceased after 1 to 3 litres of water had been retained Œdema was not to be expected unless already present in subclinical amounts, but in patients with diminished cardiac reserve the increased water load may precipitate failure Diuresis occurred after treatment was stopped, and occasionally, as Dr Kersley pointed out during continued treatment Similar observations have been reported by American workers.[17] Dr Domenjoz referred to the retarding effect of phenylbutazone on the elimination of *p* amino salicylic acid, morphine, and penicillin—presumably due again to an action on renal tubular function

No comment was made on the interesting effect of phenylbutazone on iodine metabolism During the early stages of treatment the uptake of iodine by the thyroid is depressed, apparently as a result of competition by the drug, which has an affinity for iodine; when this affinity is satisfied thyroid uptake reverts to normal [18 19]

Blood Concentration

A relation between the concentration of phenylbutazone in the blood and the therapeutic and toxic effects was described by Dr Meanock and his colleagues A daily dose of 1200 mg (high by present standards) produced a peak level in the blood after about ten days and elimination might not be complete till fourteen days after stopping treatment. A blood level of 5 to 10 mg per 100 ml produced the maximum subjective response and any increase served only to aggravate the danger of toxic effects. Control of dosage by measurements of the concentration of the drug in the blood cannot become generally feasible, but the results suggested that a suitable schedule might be an initial dose of 200 mg per day increased, if necessary, by steps of 100 mg to a maximum of 500 or 600 mg daily

Toxicity

We have lately discussed [20] the hazards of treatment, and they were considered in detail at the symposium Prof E C DODDS, F.R.S who took the chair at the experimental section, pointed out that the part of the molecule of phenylbutazone responsible for its toxicity was unidentified. There was perhaps a possibility that a related compound of equal therapeutic potency but reduced toxicity may eventually be produced.

Dr Steinbrocker had encountered toxic effects notably nausea weight gain, and rashes, in 22% of the cases in his large short-term series although there were no serious incidents among these patients, he considered that the use of the drug was fraught with hazards and that the general attitude in this country was over-optimistic Dr Newns reported a rather similar incidence of toxic effects, including another fatal case of agranulocytosis,[21] bringing the total now reported to 6 [22–25] Those examples of agranulocytosis, and others which have not proved fatal,[3 22 26–31] have all developed within the first six weeks of treatment Dr Steinbrocker insisted as have many others, on the necessity for weekly white-cell counts, but those who believe that this does little more than induce a sense of false security were supported by Dr Kersley who described an instructive case [26] in which vomiting diarrhœa, rash, and fever gave warning of impending trouble, while the white cells of the peripheral blood showed no abnormality The administration of phenylbutazone was stopped at once, but agranulocytosis did not appear until four days later Several speakers thought it essential to warn the patient to stop treatment at once and to report if fever, malaise, or sore throat developed. Dr Meanock had seen one death—an elderly patient in whom oliguria may have been precipitated by phenylbutazone.

Previous reports have thrown suspicion on phenylbutazone as the probable cause of fatal gastro intestinal bleeding [32] perforation of duodenal ulcers,[22] sudden unexplained death [6] and aplastic anæmia.[33] Jaundice has occasionally been seen during treatment, but it is hard to be certain that the drug was responsible and both Dr Domenjoz and Dr Buttle had found no histological evidence of a hepatotoxic effect in animals Ulceration of mucous membranes may occur in the absence of agranulocytosis, and Dr Steinbrocker referred to a varicose ulcer which tended to heal when phenylbutazone was withdrawn and to break down when it was given again

Dr Currie seeking to explain the discrepancy between the comparative insignificance of toxic effects (none of which had given him any anxiety) in his own very large series and the more sombre experience of others, wondered whether the simultaneous administration of barbiturates, which he was careful to avoid, might increase the dangers Certainly in several untoward incidents phenylbutazone was not the only drug being given, and Dr Steinbrocker had seen an alarmingly high incidence of gastric bleeding when it was given at the same time as gold. In our correspondence columns this week Dr Belart discusses some possible causes for the apparent discrepancies in the published reports about toxicity He favours Butapyrin' (phenylbutazone and amidopyrine) as less toxic than phenylbutazone and he finds that toxic effects are reduced if this preparation is given intramuscularly and in short courses using relatively large doses

Although the incidence of toxic reactions of all kinds in most of the published series has been high (30 to 50% in the majority) most have been mild and have not necessarily stopped further treatment. In avoiding toxic effects it may be important to appreciate three facts phenylbutazone persists in the body for a long time after a single dose failure to achieve an adequate response to a daily dose of 600 mg is an indication for abandoning treatment rather than for increasing the dose (unless, as occasionally happens the tablets are not being absorbed) and the intake should be reduced as rapidly as possible to the minimal effective level Careful selection of patients may also help though it is unfortunate that the drug may be particularly dangerous in elderly patients in whom the analgesic effects may be so valuable Certainly it is wise to exclude individuals with poor cardiac or renal function. Gaps in treatment of any ten to twenty days may increase the danger of sensitisation [26] but Dr Steinbrocker believed that a break in treatment of a few days every two weeks might be good policy

No single method of treatment is appropriate for all patients in all stages of rheumatoid arthritis and phenylbutazone is no exception—nor unfortunately is it alone in carrying a measure of danger The realistic clinician ' *as Dr Steinbrocker named him reviewing what has been* tried and what resources are left to him may find it difficult, on occasion to deny a patient badly in need of help a drug which may give him ease His decision may become simpler when further careful observations have defined the extent of the risk he has to accept, and no doubt the Empire Rheumatism Council will return to the subject of phenylbutazone at a future symposium

The Widdicombe File

IV (2) —ALL IN THE DAY'S WORK *

MY DEAR BREWER,

I am glad to know that you intend to do some of your own clinical pathology We all have a weakness for that mythical beast, the old horse and-buggy doctor, who, between daily tracheotomies and nightly cæsarean sections, cured every hysteric for miles around by force of personality alone You will be his lineal successor Do not be afraid of poaching my preserves The proper province of the general practitioner is everything which he can do without interfering with all his other duties If your venture does no more than spare me and my colleagues some wasted hours looking at normal fluids and excretions we shall be in your debt

May I make some brief comments on your plans ? The M R C hæmoglobinometer is a lovely yoke I just wonder if for your job it is not rather like using a Purdy gun for scaring blackbirds The main fault with almost every method of measuring hæmoglobin is that you must do so with a pipette Now cleaning pipettes is a nice healthy job, but it must be done while the blood is wet If you are called away as you are about to do it you will either have to put in a lot of work with caustic fluids or buy a new pipette (And you would be surprised how many blocked-up pipettes there are in the backs of the cupboards of the most conscientious doctors) There used to be a hæmoglobinometer—there may be still—which did not require a pipette but measured the blood by allowing a thin film to run by capillary action between two glass plates a fixed distance apart When you had finished you merely wiped the two glass plates clean with some dry gauze or your handkerchief There is too another trick which I learned from one of the elder brethren while sitting on a medical board Apparatus required needle, 1, corner of white blotting paper, 1 piece Prick the patient and take a small drop of blood on the paper Prick yourself and put your drop beside it Compare If your blood contains 14 5 g of hæmoglobin per 100 ml (or more or less) you will be able to detect a comparative pallor in his or her specimen if it contains 10 g or less *Probatum est* as the old books on magic say

Why use Leishman's stain ? Jenner's is easier to make and to use and leaves you in no doubt whether a cell is a lymphocyte or a large mononuclear Incidentally I used to prefer it on æsthetic grounds. I am sure you are right to eschew the counting of blood cells But if you own a hæmocytometer keep it handy Rarely, very very rarely, there are times in the middle of the night when a knowledge of the total white cell count is worth a lot Any fool can do sedimentation-rates to interpret them demands mental powers of a very high order Before you stain your vaginal swabs look at them wet —i e, in saline First you will see that some of them, despite the volume of the discharge, contain almost no pus at all but masses of desquamated epithelium Pass them by I do not know the cause or cure of this condition but I never find any infective agent in these smears Trichomonas is plain to see but I would take no heed of monilia (candida in the best circles nowadays) unless accompanied by pus Lastly I am all in favour of your syringe service It will cost a lot but it seems to come nearer to perfection than most of the tricks used by your colleagues. When the practice can run to it, buy a small electric dry steriliser I have known women so ignorant that they thought meringues more important in the domestic oven than glassware

A sprinkling of clinical pathology can bring much éclat and quite a lot of new patients to a practice. I have seen it happen When your practice has expanded to the point when the laboratory bench is used to house record cards——I will not go on May I add two words more ? Fascinating though all the gadgets are when they first arrive I believe that the mere performance of these tests will pall in time Set yourself a plan which will keep your mind as well as your fingers busy How many men and women are doing their daily job with less than 12 g of hæmoglobin per 100 ml ?, We know a lot about hospital admissions and expectant mothers but not much about the ambulant population How many young men show positive tests for occult blood who have neither ulcers nor piles ? My other precept is a graver one Never believe your results if they contradict your other observations or common sense " I beseech you, in the bowels of Christ, think it possible that you may be mistaken " Noll had the right idea An unshakeable certainty of the correctness of his own findings is the surest hallmark of an inferior clinical pathologist

Yours sincerely,

HARRY HAWKE.

N.B —Always prick the lobe of the ear and not the finger, they can't wriggle so much

*Dr Hawke is here answering Dr William Brewer's letter published on Nov 14

Medicine and the Law

Hospital Charged with Inadequate Supervision

SHORTAGE of staff in a small hospital proved to be no defence in a recent action at Monmouthshire assizes [1]

A patient who was admitted to hospital at 2 P M, was suffering from pneumonia The sister on duty stated that he had shown no sign of being irrational when she handed over charge to another sister at 8 P M According to the counsel appearing for the patient's widow, the delirium stage of pneumonia had been reached There were signs by 8 20 that the patient was slightly irrational and by 11 30 that he was definitely in that condition Some time between 1 30 A M and 3 15 he left the ward in his pyjamas with a blanket round his shoulders He tried to enter the cab of a lorry which had stopped temporarily at traffic lights The driver, being forbidden to give lifts to passengers, refused him entry Eventually the body was recovered from the river Wye, some strips of the blanket being found on each side of a bridge At 3 25 of the night on which he disappeared he was reported to the police as missing as from 3 15 It appeared that an entry " patient walked out between hours of 2 A M and 3 A M " had been pasted over the original entry "*fairly comfortable night* "

It was contended for the defence that the patient might have got up and walked out if he had remained at home The judge did not regard this argument as excusing the hospital He held that the night sister and the orderly on duty with her were negligent in leaving the man unwatched There was also negligence in the staffing of the hospital The defendants knew that the patient was suffering from a dangerous disease and that delirium at some stage was likely A medical witness, called by the plaintiff, had expressed the view that one trained nurse and a ward orderly with a night porter were insufficient night staff in relation to the case The hospital matron said the system of locking the outside doors of the hospital and leaving the key on the inside was the best possible

Damages of £3049 were awarded by the judge to the widow and infant daughter

---

Parliament

Fog and Public Health

In the House of Lords on Nov 18, Lord **Amulree** rew attention to the danger caused by fog to the health f the people of London and asked what progress had been made in making available an adequate supply of smokeless fuel for domestic use It was estimated that, during he fog of 1952 4000–5000 people died from the effects of he fog, and the sickness claims for the Counties of London and Middlesex were doubled Recording machines howed that during the fog the concentration of sulphur dioxide in the air was five times the normal of the previous hree days. Great care was taken about the purity of food and water, but not so much about the air which Lord Amulree pointed out, was one of the most important foods we took in Smokeless fuels would go far towards abolishing fog, and a second remedy was the formation of smokeless zones by local authorities under the Public Health Act 1936 He wished to know what treatment was given to the fumes from the large power stations All these remedies, he admitted, would cost money but fog was also expensive in its effects on public health

Lord **Haden-Guest** believed that one of the difficulties in London at any rate was the absence of any central authority dealing with London as a whole He thought we would have to forbid altogether in the London area the use of fuel which emitted smoke

The **Earl of Selkirk**, Paymaster-General replying to the debate, said that there was little danger to health from pure fog the danger only arose from polluted fog He went on to compare the 1952 fog with the cholera epidemic of 1866 when the Thames was an open sewer and 14 000 people died Enormous sums of money had been spent on public sanitation since 1866, and the cleansing of the atmosphere would demand much the same resources. Smog was no danger to people in good health, but people with heart or chest diseases should seek their doctor's advice. A mask would give some protection against solid particles, but he agreed that it would not protect the wearer against the gaseous contents of smog

Turning to the smokeless fuels, he said that they cost about half as much again as coke. Unless their cost was brought within reach of the average householder he doubted if they would make more than a small though valuable contribution to smoke abatement. The total quantity on the market was less than 1 million tons, against 85 million tons of coal and 3 million tons of coke But progress had been made in changing over to smokeless fuels. London for instance was consuming no more coal, but more smokeless fuel, than it was ten years ago, while the domestic consumption of gas had gone up by 50% and of electricity by 100%. The public, he added should be warned against banking up fires at night in foggy weather In London it would not be enough to create small smokeless areas as had been done in Manchester and Coventry unless similar action were taken to windward in neighbouring districts.

Capital Expenditure on Hospitals

On Nov 16 Mr **Cyril W Black** asked the Ministry of Health to reconsider their refusal to sanction small structural alterations at the Nelson Hospital, Merton The proposed alterations, which had been approved both by the group management committee and by the regional hospital board, would cost about £3000; and need only about 1¼ tons of steel and about 0·5 standards of timber The regional hospital board was unable to provide the money, but King Edward's Hospital Fund had offered to provide the sum necessary Yet the Ministry of Health had refused to sanction the project owing to the Treasury arrangement for capital allocations

Miss **Patricia Hornsby-Smith** parliamentary secretary to the Ministry said that the Minister would greatly regret if there were any suggestion that he did not welcome help from voluntary sources for the health services But it must be understood that for capital projects they still had to conform with the overriding national policy The present system of controlling capital investment was based on economic considerations which extended beyond the control on Government expenditure as such, and even beyond the control on building materials. As a result the allocation of the Ministry of Health must cover all hospital work, however financed, and if a regional hospital board accepted money from outside it still had to toll against their own over-all capital allocation.

Private Members' Bills

Colonel **Malcolm Stoddart-Scott** who was successful in the ballot for private members Bills, on Nov 18 introduced a measure to make it compulsory for the exchange of certificates of medical examination between persons before marriage. The second reading has been fixed for March 20

On Nov 18 Mr **G D N Nabarro** presented a Bill to amend the law as to the fees and allowances payable by coroners to witnesses to persons summoned to attend as witnesses, and to medical practitioners making post-mortem examinations at the coroner's request The second reading has been fixed for Feb 12

QUESTION TIME

Examination of Limbless Pensioners

Replying to a question Mr **Osbert Peake**, Minister of Pensions and National Insurance said he had not yet received the final report of the Rock Carling Committee on limbless pensioners. The special examination of several thousand pensioners for which the committee had asked was taking longer than expected.

Mr **C J Simmons** Cannot the Minister give us any idea at all when this committee will report? They have been sitting for an inordinately long time and these limbless pensioners are dying at the rate of 1000 a year I am very angry about this and I hope that the Minister will realise that the men for whom I am speaking need immediate attention and not procrastination Mr **Peake**: The committee was composed almost entirely of doctors and they disagreed among themselves. As a result we are undertaking this considerable examination of some 4500 limbless ex-Service men. We want it to be a thorough examination because the results of the inquiry will be of world wide importance. I regret that the examinations are taking longer than was at first expected. I hope they will be completed early in the year but after that the results will have to be brought together and examined

Replying to a question Brigadier **J G Smyth**, parliamentary secretary to the Ministry of Pensions and National Insurance, said that the number of deaths among limbless pensioners during the five years ended March 31 1953, were 674, 717 758 and 874 respectively

Capital Allocations for Mental health Services

Mr **H A Marquand** asked the Minister of Health for which years since 1950 circulars were sent to regional hospital boards advising them to set aside for expenditure upon mental health services, a minimum proportion of their capital allocations what those percentages were for each year and what was the total capital allocation to the hospital service in each of those years.—Mr **Iain Macleod** replied: Annual circulars from 1950 onwards about hospital capital programmes have stressed the need to make appropriate provision for mental health but none of them has mentioned a specific percentage The following figures show total capital allocations to the hospital service annually since 1950 and the proportionate value of mental health projects included in the programmes of regional and teaching hospital boards or financed outside their programmes:

	Total capital allocations £ million	*Proportionate value of mental health projects*
1950–51	9·5	15%
1951–52	9·0	21%
1952–53	7·9	18%
1953–54	8·0	15%
1954–55	10·0	

* Hospital board programmes not yet available but 13·5% of allocation set aside centrally for mental health projects. This is in addition to the provision that will be made by hospital boards.

Dentists Bill

Mr **Frank Beswick** asked the Minister if in view of the delay in proceeding with the Dentists Bill, he would bring forward that non-controversial part which would make it possible for dentists with qualifications obtained outside the United Kingdom to practise in this country —Mr **Macleod** replied No. The Bill will be reintroduced in full when Parliamentary time permits.

In England Now

A Running Commentary by Peripatetic Correspondents

MANY people have noted the decline of that fine old medical institution, the Bedside Manner, but no-one has recorded the rapid and significant rise of its usurper, the Bed-end Manner Yet this new technique of commenting on patients' lesions, treatment, and prognosis from the foot of the bed rather than from the side is one of the really big developments in Medicine in the past couple of decades The phrase is a complete comment on the gradual abandonment of physical signs and the substitution for them of the broad-spectrum (if I may use a popular word) investigation

It is in hospitals that the Bed-end Manner flourishes, and I have seen some of its finest examples in the teaching hospitals The first important principle is that no doctor shall approach a patient alone all approaches must be made en masse during the Grand Round This effectively prevents any single doctor from speaking confidential and comforting, if highly unscientific, words to the patient This means in effect that nobody ever speaks to the recumbent victim except an occasional wardmaid and the man with the newspapers No doctor must utter a sound, since it is obviously "someone else's duty to undertake that type of thing" The en-masse approach also prevents a salutation at any level between physician and patient, because as the caravan approaches the bed the Chief stage-whispers "What is she ?", the menial turns to answer the question, and the golden moment is gone

History-taking, a transient and ever-dwindling procedure, may still be undertaken by a house-officer in the lamentable absence of a dictaphone or a suitable "cross out that which does not apply" type of questionnaire But happily many other scientific devices for keeping the doctor from the patient have been perfected Auscultation is unnecessary in view of the electrophonograph, the electrocardiograph gives us the pulse-rate, and the lowered serum-potassium tells us that it is full The barium meal shows us the cause of his vomiting, and the ventriculograms give a cause, if not the original one, for his headaches "His cardiac catheterisation leaves us in some doubt, Sir" "Yes, yes, ahem, you'd better repeat it" Pulse charts and temperature charts are consulted only if the patient is seriously ill and the diagnosis obscure, and much of the value of the latter is lost by the enthusiasm of the house-officer, who achieves uniformity of temperature throughout the ward by giving massive doses of the latest 'mycin to every patient By these means all moves to the bedside are obviated, unless to remove a bedpan or on some similar mission—duties that are carried out at an appropriate level

Above and beyond all, the patient must be told nothing If he is in a surgical ward and has keen hearing, he may catch the word "Thursday," which means that he will have his operation on Thursday If he is in a medical ward, he may hear the explanatory remark "catechol amines" which means that he will have his cate . (whatever they are) estimated

The Bed-end Manner is a sign of changed medical times all right Still one can't help feeling—just now and then of course—that this change means more to the patient than antibiotics, anæsthetics, electrolytes, psychiatrists, old uncle Tom Cobbleigh and all Graph-paper has replaced the leech in therapy Is either ideal ?

* * *

Having occasion to travel to the Outer Isles at a time when all good sailors are reading the trade journals for home berths my friend found himself at his destination dealing with the combined ravages of post mal-de-mer and active mal-de-terre Only the hope of dying, he affirms, kept him alive on the voyage

However, not for nothing does my friend treat peptic ulcers with bottles and soul-searching talks With this spirit of medical faith and determination he hurried aboard on the evening of his homeward voyage filled to his pharmacological capacity with three brands of anti-seasickness pill, scorning in passing their official equivalent, plus a double dose of the barbiturate he usually reserves for old ladies with high blood pressure and no housework Shakily he made his way to his lower berth in the depths of the ship

He states that on the whole he had a good night. True he found himself on the floor twice Once he was certain that they had turned turtle and he would have abandoned ship, but his fingers were inextricably enmeshed in the rack where his clothes should have been Nevertheless he was inclined, all in all, to be satisfied with the triumph of medicine over the elements

It was only when he arrived on deck next morning that he felt unwell "Och, yes indeed," said the captain sympathetically "Wass it not the wild night, last night It is a terrible pity we were not able to leave the pier at all, at all" It was now Sunday, my friend had no more pills, and the chemist was an elder in the kirk

* * *

I have just thought of a way of getting a lot of money for psychiatric research We point out to the Government that the atomic bomb and its offspring are being outmoded and that the next war but one will be fought with psychological weapons They will then earmark a couple of million for us, for Defence Prototype E.E.G. machines will be dashed off at enormous expense and at super-priority Vast tracts of the country will be taken over to discover which holiday areas are the most satisfactory for rehabilitation Beautiful country houses will be allotted to the training of registrars. B O A.C planes will be full of consultants hopping from London to Paris, then over to Washington We shall have steel and bricks for the asking, and can build hospitals The Russians will claim to have invented psycho-analysis. Senator McCarthy will state that unconscious motivation is an un-American activity Hollywood will make a film about the life of Freud, with six new hit tunes.

* * *

My peripatetic colleague who complains that so many letters in the correspondence column being "I have read with interest" does not seem to realise that letters reaching the Editor do not always leave his office unmodified Thus a letter written in heat to the Editor might read

"If your correspondent had the nous to turn the nut on the CO_2 cylinder to the right he might find his anæsthetic mortality reduced"

On emerging from the editorial mill of good manners this might well read

"I have read with great interest Dr Smith's letter on his increasing parabola in anæsthetic mortality These are difficult days and gas is not what it used to be Moreover, the machine itself is manifestly manufactured to confound and confuse It is constructed on very similar lines to modern poetry, almost impossible to comprehend, but one feels that beneath it all is a meaning and use However, Dr Smith may find it an advantage to turn the nut on the CO_2 cylinder This is done by turning the spanner clockwise"

* * *

The Mad Electrolyte's Lament

Oh, if only I had a slide rule,
In my tiny little head,
I could please the white haired doctor
And get back to my own wee bed

But our union rules are rigid,
We must spurn the grammes of men
And the dance that we dance together
Pays no heed to the decimal ten

I've tried a reducing diet
To get my weight down to my pal's
But all that has happened is fission—
So look out for schizoid squalls !

I've asked the membrane potential
To let me out once again
But he says now he doesn't know me
So I'm still in my little pen

Oh, doctor, please forgive me,
If I can't be as clever as you.
I don't understand your units,
But I do know what to do

Letters to the Editor

SUBCLINICAL POLIOMYELITIS INFECTIONS

SIR,—Your leading article of Nov 14 might be read as the last word in the discussion on the Prevention of Poliomyelitis which engaged your columns recently If so, I am at issue with you on several points.

(1) Few students of poliomyelitis would agree that sufficient facts have been marshalled to justify your conclusions. You say "Quarantine restrictions against poliomyelitis have been likened to closing the stable door after the horse has bolted They are better compared to mending the bottle after most of its noxious contents have already escaped, the attempt to prevent the last few drops from escaping however desirable, should be viewed in the light of the damage already done This new evidence [Melnick and Ledinko [1]] will discourage the adoption of stricter quarantine measures.'

(2) Dr Melnick is an eminent microbiologist He is well aware of the complexities of the serology of virus diseases [2] and might feel uncomfortable as your main support when you lean towards inaction You have not mentioned his evidence [1] that at Winston Salem the upper socio-economic group appeared to escape infection during the 1948 epidemic This suggests that, even at the end of an uncontrolled epidemic, there was a 'limited selective distribution' [3]

(3) In 1950 I said [4]:

> "During 1949 two or more cases in a household were not infrequently reported. This seemed to happen when there was a particularly high incidence in a hamlet village or small town. Already this year there have been several instances; for example in the Isle of Wight there were three cases of disease in each of three households The phenomenon is interesting because when it occurs a chain of contacts between households can be defined more easily than is usual in poliomyelitis and the disease appears to be spreading in a narrow stream of the population, healthy intermediaries or persons with ill defined illnesses providing some of the links.

And in 1952 [5]:

> Some of my colleagues and myself have come strongly to the opinion that poliomyelitis virus causing *disease* moves through a narrow stream of the population.

It is important to distinguish between 'disease' (now printed in italics) and 'infection' in the serological sense * Melnick [1] also comments upon certain similarities in the distribution of persons with poliomyelitis antibodies and with antistreptolysin. In regard to scarlet fever we do not base control measures upon antistreptolysin titres but upon manifestations of the disease.

(4) Examples of 'narrow stream' spread have now been recorded by many field workers. The phenomenon is capable of description and as such it has the qualities of a fact which cannot be ignored. Moreover, it is a phenomenon which until recently had not been seriously considered in framing our concept regarding the epidemiology of poliomyelitis It seems very probable that disease-producing polio virus is far from ubiquitous,[3] and that there may indeed be hope of devising general measures for controlling its spread.

(5) There may be some uncertainty regarding the word 'quarantine,' which means detention or limitation of the freedom of movement of persons who may transmit disease—a method nowadays rarely used in the control of any disease smallpox included. It is simple enough to stop typhoid carriers infecting others without quarantine when they understand the problem While I agree with you that stricter quarantine measures are not indicated in the control of poliomyelitis, I believe there is new evidence which encourages greater effort to prevent the case and the contacts from spreading infection, particularly at the beginning of an outbreak The matter is discussed more fully in the *Medical Officer* of Nov 21 and a more authoritative statement by a W H O expert committee is to be expected in the New Year Your readers will I think wish to suspend judgment.

THE INSULIN MYTH

SIR—Dr Bourne's article (Nov 7) should not go unchallenged because I feel that some patients would undergo much unnecessary suffering if his views were generally accepted. I wonder how much insulin treatment Dr Bourne has himself given before putting them forward. Having used both insulin and E.C.T in the treatment of schizophrenia since 1937 I have still not the slightest doubt of the clinical superiority of insulin in many patients, though the best results can sometimes be obtained when both are skilfully combined.

Dr Bourne's selected statistics remain unconvincing when one knows the number of other statistical studies and opinions he has glossed over or omitted including those of Mayer Gross a recognised world authority on schizophrenia and its treatment, Freudenberg, Müller Finiefs and Polonio He also omitted to point out that opinions on this matter were collected from many countries for the International Congress of Psychiatry in Paris in 1950 and then analysed by Neveu [1] who found *that insulin was the generally accepted treatment for* this condition. Insulin is certainly not a specific treatment for schizophrenia but the best we have available at present for many patients in the early stages.

Finally is there anybody in this country who has had several years, continued personal experience of *both* insulin and E.C T in this condition in large numbers of patients, and who really believes E.C T to be the better routine treatment of the early case? If so I do hope they will write and say so

Department of Psychological Medicine
St. Thomas's Hospital,
London S E 1 WILLIAM SARGANT

SIR—One must congratulate Dr Bourne on putting forward his views so forcibly supported by selected quotations His commentary on the use of insulin in schizophrenia demonstrates how easily irrational therapies are introduced how readily they are accepted, and how hard they die

1953 may be a convenient time to review the position because insulin therapy for schizophrenia was introduced just twenty years ago Since then a great deal of time, money, effort, journal space, and hope have been devoted to this particular biochemical method of directly attacking the psychotic's brain Bellak [2] lists over 700 references in the period 1936 to 1946 alone.

The particular 'difficulties of assessing any treatments in schizophrenia' to which Dr Bourne draws attention are of course seen throughout the field of psychiatric therapy For this there are three main reasons. Firstly 'the lack of mental theory in psychiatry' [3] leads to wide variations in diagnosis from psychiatrist to psychiatrist and from hospital to hospital. Secondly psychiatry is peculiar in that the criteria of improvement are vague, ill defined, and highly subjective, both from the patient's and the therapist's point of view Psychiatry is in fact uniquely backward among the medical sciences in that signs and symptoms are equated with the disease itself —because the nature of the disease process is so little understood This lack of distinction leads to treatments aimed at abolition of symptoms, and the acceptance of recession of symptoms as the measure of improvement Yet it is open to question whether, for instance, a schizophrenic temporarily deprived of the overt signs and symptoms of his illness—a state of what might be called induced anosognosia—is more normal or even better off in the long run The third difficulty in assessing therapeutic results is that physical methods by which psychoses are at present largely treated are entirely empirical What anatomical, physiological, or other basis there may be for their action is still a matter for speculation and hypothesis—a fact recognised by their most ardent advocates Further, physical methods of treatment themselves produce an abnormal picture, characterised by loss of spontaneity, loss of memory for recent events, diminution or loss of overt signs and symptoms of illness, and increased socialisation and hence easier management These are taken as evidence of therapeutic success, and little attention is paid to the price in concomitant over-all reduction of mental function During and after recovery from such treatments, the signs and symptoms of the underlying illness may remain permanently in abeyance , or they may recur—an eventuality which Dr Bourne graces with the description " relapse after withdrawal (of) convulsion therapy " Whether in such circumstances repeated administration of physical treatments with the recognised risk of permanent brain damage is justified, will remain doubtful till we have the results of long-term studies If this question is to be decided on assumptions—and Dr Bourne's statements on convulsion therapy are of this nature—one might assume with equal justification that the need for maintenance doses arises from, and is an indication of, failure of the initial treatment

[2] Bellak, L. Dementia Præcox. New York. 1948.
[3] Macalpine I Critical Evaluation of Psychosomatic Medicine *in* Modern Trends in Dermatology edited by R. M. B MacKenna. London, 1953.

I therefore take strong exception to Dr Bourne's statement that " the schizophrenic patient may be as dependent on E C T for a normal existence as a diabetic is on insulin " Such a comparison is surely as much an affront to the scientific physician and the physiologist as it is a grave danger to the schizophrenic Unlike the use of insulin in diabetes, shock treatments are empirical and unbiological, and neither their mode of action nor their effect is measurable The argument that shock treatments cause no mental impairment, as judged by psychological testing, does not carry much weight even after leucotomy, in which areas of cortex are destroyed, isolated, or removed, psychological tests are often reported as not revealing organic deficit The only possible conclusion is that the tests themselves are of limited value

London S E 1

RICHARD A HUNTER

SIR,—Dr Bourne's article contains a number of assertions and claims which cannot be allowed to pass without comment

The article, in effect, is a special plea for E C T in preference to insulin coma therapy in the treatment of schizophrenia He attempts to support his case by reference to selected papers and to results obtained in a group of soldiers suffering from schizophrenia

A number of important papers on the value of insulin are not mentioned—e g , Mayer Gross,[1] Bond and Rivers,[2] Bond and Shurley,[3] Garmany,[4] and Finiefs [5] The work of Freudenberg [6] is not given the attention it deserves

Dr Bourne discusses possible fallacies in attempts to evaluate treatment methods for schizophrenia, but gives no evidence to indicate that he has dealt with these in his own series His group is highly selected, as it consists of soldiers No details are given on methods used in assessing recovery His follow-up refers to only half the group and he relies on information obtained by letter for his follow up assessment It is doubtful if any reliance can be placed on information obtained in this way There is no evidence to show that the groups treated by different methods are in fact comparable in important respects Finally he ignores the time factor in assessment, the importance of which I have stressed,[7] and to which Dr Russell Davies refers in his letter (Nov 14)

It is very doubtful if any valid conclusions can be drawn from Dr Bourne's data Comparison of schizophrenia groups treated by different methods will be vitiated unless it can be shown that the groups correspond not only in age and sex distribution, but in clinical status and tendency to spontaneous recovery All groups should be assessed by the same standards and criteria and preferably by the same person

Dr Bourne makes reference to a number of isolated points in an article of mine [8] He pays little attention to the methods used to deal with the inherent pitfalls in attempts at assessing psychiatric treatment methods, but stresses what appears to him to be a numerical discrepancy which I am happy to explain He refers to a group of 18 patients who failed to respond to various methods of treatment He incorrectly assumes that all 18 patients received E C T , insulin, and electronarcosis The actual position was that all 18 patients received insulin and E C T , and of these 9 had electronarcosis as well This amplification of the data explains the apparent discrepancy

To deal with further points raised by Dr Bourne, I am able to say that the group of 160 schizophrenics studied were not derived from a larger group, but were consecutive admissions over a period He assumes that the E C T dosage was inadequate In fact the majority of patients treated by E C T had 25–35 treatments and some as many as 50 In a paper [8] to the International Congress of Psychiatry, statistically controlled studies showed that insulin-coma therapy was the only method giving significantly better results than routine hospital care The results gave no support to Dr Bourne's claim of the superiority of E C T in the treatment of schizophrenia Furthermore the relapse-rate with insulin was much lower than with E C T or electronarcosis In no patient did E C T produce recovery after insulin had failed, whereas in 16 patients in whom intensive E.C.T produced no improvement, insulin coma therapy resulted in recovery or considerable improvement

Dr Bourne points out that any positive results obtained in chronic patients may be regarded as significant In a group of patients with long standing schizophrenia of poor prognosis, insulin was the only method giving total recovery, which was achieved in 8·4% of such patients treated with insulin and in none treated by E C T or electronarcosis.[9]

The complexity of psychiatric material and the inherent difficulties of assessing psychiatric methods of treatment demand the rigorous application of scientific, statistical methods with adequate controls and follow up studies over long periods Dr Bourne will have to provide data which meet scientific requirements before his claim for the superiority of E C T over insulin-coma therapy in schizophrenia can be accepted

Cardiff.

LINFORD REES

SIR,—Many will sympathise with Dr Harold Bourne's youthful impatience and his critique of the empiricism of modern physical treatments in psychiatry , but very

w will agree with him when he replaces what he calls e "insulin myth" by a plea for convulsive therapy, eoretical dissatisfaction equally refers to either rocedure. As to insulin-coma therapy, against which is attack is directed—i.e., Sakel's method of treating hizophrenics by hypoglycæmia—this has been severely nd authoritatively criticised for many years—for stance by Bleuler,[1] who based his objection on statistical aterial of his own observation Nevertheless most linicians have refused to abandon the method and others ave even resumed it during the last few years. The easons are explained in Max Müller's monograph which ou recently reviewed[2]: it is the only treatment that olds out some hope of shortening and relieving schizohrenia, the major medical and social problem which r Bourne wants to save from the "mere parochial oncern of psychiatrists", he does not say to whom he ants to hand over the treatment of these patients My wn views on the treatment are still those I expressed in 947[3] and 1950[4] when I compared results obtained at richton Royal with an untreated control material from he Maudsley Hospital chosen for their *optimal prognosis* n 1938.[5] Both groups had been diagnosed by the same linician according to the same diagnostic determinants. If I may be allowed to quote one result of my ollow-up study of 454 schizophrenics treated between 1939 and 1947, I found that after three years 57% were total or social recoveries as against 34.5% of the control group It was also shown that although insulin therapy does not prevent relapse, it does not provoke it, after shortening the attack of the illness. Relapses can be successfully treated by another course of hypoglycæmia a second and third time—in what proportion will be the subject of an investigation of our follow-up office in 1954. That hypoglycæmia—like the treatments for cancer and tuberculosis—has its best results in early cases, and that it helps patients with a tendency to remission, can only speak in its favour because it supports Nature's curative tendencies. That it has to be combined with general rehabilitation to yield its full effect, seems equally natural to the clinician who looks at his patient without theoretical blinkers Moreover the rationale of hypoglycæmia as a therapeutic procedure is thanks to the work of Quastel, Himwich and Gellhorn much better founded than one would deduce from Dr Bourne's article I must not encroach further on your space by repeating what I have said before on the non-specific nature of the treatment, on the rôle of the insulin fit, on the combination of coma with convulsions, and on the other worries of our critic How plausible it would have been to write a paper on the 'salicylate myth' before and even immediately after the discoveries of the antirheumatic effect of cortisone and A.C.T.H !

MILLI EQUIVALENTS

SIR,—In his letter of Nov 7 Dr Ennis draws attention to the difficulties facing clinicians in their interpretation of results expressed as milli-equivalents in acid base studies. I sympathise with the viewpoint expressed, for I have found no subject in medical and scientific work over 20 years, more difficult to grasp than that of acid-base balance. I feel that perhaps the subject is made obscure and muddling by unnecessarily loose and careless terminology It should be possible to explain mechanisms of pH variation without reference to the words acid, base, acidosis, alkalosis &c, with more exact emphasis on the essential nature of the change —i e that of hydrogen ion concentration

Electrolytes are now so fashionable that I feel that physiologists and pathologists should make every effort to clarify the subject. A start could be made in medical schools new literature, and new editions of textbooks, so that we may begin to have a generation of doctors who feel no antipathy to biochemistry and have no difficulty in the use of the term '*milli-equivalents.*'

Kingston Hospital Surrey　P DAGNALL.

TOXICITY OF PHENYLBUTAZONE

SIR,—I should like to draw the attention of your readers to the fact that on the Continent phenylbutazone was first tested pharmacologically and used clinically in 1949[1-3]

It was chiefly employed as 'Butapyrin' ('Irgapyrin'), consisting of phenylbutazone and amidopyrine (750 mg of each injected intramuscularly in 5 ml.) In spite of the fact that this drug has been extensively used, it has proved to have a very low toxicity But it is striking how often toxic effects occur in Anglo-Saxon countries, where pure phenylbutazone is employed Is this apparent discrepancy in toxicity due perhaps to greater reticence on the part of Continental doctors in publishing their failures, or is toxicity on the Continent in actual fact less ?

From my own experience over a period of five years in about 1000 cases treated with butapyrin and an equal number treated with phenylbutazone I think I can say that untoward reactions are much less frequent here. What is the explanation ? I think there are three factors : the first concerns the drugs themselves and the second and third the mode of administration.

(1) I, too found phenylbutazone more toxic than butapyrin Whereas with butapyrin, apart from œdema and rashes I met with no side-effects of any consequence (and certainly no case of agranulocytosis) untoward effects with phenylbutazone were more frequent, although much less so than in English and American reports. Besides œdema, I saw 1 case of severe gastric hæmorrhage 3 of massive hæmaturia, 2 of purpura, and 4 of severe angioneurotic œdema. This striking difference between the two drugs is surprising, for one would expect butapyrin to be more toxic in view of the large amount of amidopyrine it contains. One wonders whether the two substances have antagonistic actions, making butapyrin less toxic. I found support for this thesis in a case of massive hæmaturia in a 31 year-old man, who had had for eight days 800 mg of phenylbutazone daily The hæmorrhage recurred after the administration of phenylbutazone was resumed. But later there was no hæmaturia, when he had 1200 mg of butapyrin daily

(2) In England and America phenylbutazone was introduced in dragée form. This led to smaller doses being given (600 mg and less per day) but treatment was continued for weeks and months. On the Continent butapyrin came on the market only in high-dose ampoules (750 mg of phenylbutazone) The technique was developed of giving butapyrin in short courses of 3–5 high-dose injections at intervals of one or two days. This boost therapy proved particularly *valuable in acute and subacute attacks of rheumatoid arthritis,* degenerative joint diseases, and fibrositis. But here the drug is not used for prolonged treatment of rheumatoid arthritis. This Continental method of administration may perhaps be one of the reasons for the rarer occurrence of untoward effects since it is clear that when the drug is given for short periods sensitivity phenomena are less frequent.

(3) A further reason for thinking that injection technique reduces toxicity is provided by Brodie and Burns.[4] They showed that phenylbutazone in man combines very firmly and quickly with protein. When it is given by mouth this change takes place in the blood ; when it is injected intramuscularly however the change occurs in the muscle protein Therefore the serum level of the drug rises much more rapidly when it is given by mouth. The "shock effect of the dragées is thus greater This is perhaps the reason why of my 10

toxic cases, 5 had been treated with dragées—a method which I personally rarely use

For these reasons, it seems to me advisable to choose intramuscular injection rather than the oral route, short courses rather than long ones, and butapyrin rather than phenylbutazone

Zürich **WALTER BELART**

URINARY EXCRETION OF CITRATE

SIR,—Our preliminary communication of Sept 26, reporting very low rates of excretion of citrate in the urine during potassium deficiencies, was made because we thought the observation interesting, although we were unable to explain it On the basis of some findings of his own, Dr M D Milne (Oct 3) suggested that the fall in citrate excretion in our experiments could be explained by a diminished urinary excretion of calcium Indeed, according to Dr Milne, there might have been a greater fall in citrate than we observed Our analyses, however, which have now been completed, show that the urinary excretion of calcium was not reduced during our experiments, indeed the output of calcium in the urine was sometimes greater during the potassium deficiency than it was during the control periods, although we used a cationic exchange resin to produce the potassium deficiency This is in keeping with the finding[1] that, although the resin may combine preferentially with calcium in vitro, it did not increase the fæcal excretion of calcium in experiments similar to those in which the observations on citrate were made

It would seem, therefore, that our results cannot be explained along the lines suggested by Dr Milne and that there must be some other reason for the fall in citrate excretion

THE DRUG BILL

SIR,—I suggest that one of the best ways of keeping the N H S drug bill under control would be to cultivate a healthy sense of therapeutic nihilism That literally millions are spent each year on medicines is testimony to our pathetic credulity as doctors It is often stated that doctors are much under the influence of the manufacturing chemists, but the doctor who allows himself to be unduly influenced by the manufacturing chemist's blurb must surely be very young or very naïve, or both, and in this, and in many other things, it is only Time; presumably, that will bring a cure Or does the elderly doctor sometimes fall as easy a victim, on the principle that there's no fool like an old fool ?

During the late war, rendered almost desperate by the importunity of some old lady demanding something I didn't quite know what, I gave her—let it be confessed—a prescription for Mist Ferri Aperiens, without any regard to her particular complaint The next week her gratitude was almost maudlin in its excess because, as she said, my medicine had given her " such a lovely sleep " Equally surprising are the patients who tell you that they have a " wonderful appetite " as a result of taking a bottle of Mist Sod Salicyl Perhaps it does have that effect on some people Who knows ? But it wasn't what I was taught to expect

A recent copy of *Prescriber's Notes* gives details of the surplus drugs recovered from a patient's house following his death The total cost of these was stated to be about £40 Those of us who rarely write a prescription without at least bestowing a little thought on its cost and the probable extent to which it will really help our patient, can only sit back and meditate (without undue smugness) upon the mentality of doctors who squander the nation's resources with this kind of reckless prodigality

G P

ISCHÆMIC NECROSIS OF THE STOMACH

SIR,—I think the unfortunate complication of a subtotal gastrectomy, described by Mr Rutter (Nov 14), can be attributed not so much to devascularisation as to a possible technical fault in planning

His description of the first operation, where he removed the whole of the lesser curve, is rather confusing, since at the second operation he found an ulcer on the lesser curve, but it would appear that the necrotic ulceration was due to the nature of the operation—i e, Bilroth I—whereby extreme tension is placed on a partially devascularised cardia

I would suggest that had he closed the duodenum and constructed a Roux's en Y gastrojejunostomy, either retrocolic or antecolic, preferably retrocolic, the complication he described would probably have been avoided

Memorial Hospital, Peterborough **D W BRACEY**

LACTIC ACID IN THE TREATMENT OF OSTEO-ARTHRITIS

SIR,—Dr Lawrence, in his article of Oct 31, ended his summary " It is concluded that lactic acid has no therapeutic action in osteo arthritis " In fact, surely, his paper justified no such conclusion The most he was entitled to say was that the addition of injections of lactic acid, for a short period, to adequate physiotherapy make no difference in cases of osteo arthritis To warrant the conclusion which Dr Lawrence drew, he must compare untreated cases with cases treated only with injections of lactic acid, and I venture to think he might have reason to change his opinion

It was in a thoroughly sceptical frame of mind that, following a visit to Mr Grant Waugh's clinic at Darlington, I started injecting procaine lactic acid in some of my more obstinate cases of osteo arthritis six years ago The first cases had all received physiotherapy for a long time, and the average duration of symptoms was over four years Because of my scepticism these patients received no psychological boost from me to aid their improvement, but their degree of betterment was such that very soon this clinic " snowballed," so that for the last five years an average of 100 injections of joints have been given weekly, in spite of the fact that we only inject as a routine once a fortnight Being rather overwhelmed by these numbers, we often try to cut down the attendances by dismissing, for three or four months, all cases whom we do not find we are benefiting objectively The majority of these return to ask for more injections because, although they do not improve with them, they do get worse without them I would suggest that in cases of osteo arthritis of long duration, eight weeks is much too short a period in which to assess results, especially in hip joints, which I agree respond poorly to this form of treatment

It is probable that Dr Lawrence and I view this matter from very different standpoints He is a consultant dealing with " male employees of the National Coal Board "—in other words, with patients who, while off work, can rest as much as he requires them to and who, working or not, can attend hospital as often [illegible] necessary for treatment As one of the fast dwindling group of practitioner specialists, I see the patients in their daily lives as well as at hospital—women and the aged, as well as men of working age, and people who have to be transported to hospital from a radius of [illegible] miles Moreover, owing to economic difficulties, the physiotherapy department is extremely overcrowded and understaffed, so there are several other factors to be considered

In practice one fights a continual battle of compromise between what is the best possible treatment for a patient and what is the best treatment possible for that particular patient A major factor is the time spent not only by the patients but by those attending them—in this case doctors, transport drivers, physiotherapists, and those at home who do the work of the patients while they are attending hospital.

---

[1] Fourman, P *Brit med. J* 1953, I 544

From my own experience I would suggest that in very many cases one injection of procaine lactic acid, given every two to four weeks, combined with simple home exercises, keeps a patient as mobile and pain free as two or three attendances a week at the physiotherapy department Neither is a cure for osteo arthritis, neither will work in all cases, but to deny some small place for the value of procaine and lactic acid seems to me to be quite irrational on the known facts

County Hospital, York. EDWARD S VERGETTE

HYPOTHERMIA

SIR,—In his letter about refrigeration anæsthesia last week, Dr Beard refers to having cooled ' two well covered adult females for surgery of the aorta Since, in fact, he means two women it might be better to use this simple Anglo-Saxon description, which incidentally makes it clear that he is not discussing guineapigs Besides, if we stick to the old habit of calling our patients men and women we shall be more likely to regard them as persons rather than as subjects for some of the more hazardous and experimental techniques which have recently made some of your correspondents uneasy about ethical standards in clinical research

London, W1 DAVID LE VAY

HYALINE MEMBRANE IN THE NEONATAL LUNG

SIR,—The discussion that has followed Dr Claireaux's paper of Oct 10 suggests that ideas in this country are following behind those on the other side of the Atlantic A summary by Dr Clement Smith[1] of a symposium in Philadelphia last April on ' hyaline membrane disease (or syndrome) ' has come into my hands during the last few days. His summary seems the most impartial statement of the present knowledge of this condition that I have recently seen, and may be of interest to your readers

"1 The percentage of autopsies showing hyaline membrane formation is highest amongst premature infants, especially those weighing from 1000 to 2000 grams but the incidence is by no means limited to deaths in that gestational age group In our hospital, roughly 50 per cent of the infants who die after premature birth show hyaline membranes and 25 per cent of those dying after full term birth also show them.

"2. The membranes are rarely found if death occurs less than one hour or more than five days after birth It may be that one etiological class of membranes makes up the major group found after death in this age group while another cause may be responsible for those occasionally found in later deaths

"3 Histo-chemical technics are not yet delicate enough to identify the exact chemical composition of membranes beyond the general probability that it is basically protein rather than fat.

"4. The term membrane is perhaps unfortunate in that the same material may apparently occur either as a plug which traps air beyond alveolar ducts with resultant emphysema or resorption atelectasis or as a true membrane spread along the alveolar epithelium.

"5. Pulmonary edema hemorrhage and pneumonic exudates are sometimes found in association with hyaline membrane formation. The group favoured the idea that whether these latter findings were present or not, the membranes tended to be rather generally distributed if found at all and presumably offered significant mechanical interference with respiration

"6. Considerable evidence throws doubts on published theories that aspiration of amniotic fluid is the source of the protein ultimately dehydrated and compressed into these structures. Although membranes have been produced by intra-tracheal injection of human amniotic fluid into excised guineapig and mouse lungs artificially ventilated, the 15 to 20 cubic centimeters of fluid required to bring this about would mean that the infant would have to inspire a relatively tremendous amount of amniotic fluid to bring about a similar train of events. Another difficulty of the amniotic fluid aspiration hypothesis is that it rests largely on the assumption that intra uterine anoxia or similar insult is the stimulus to the inhalation of excess amniotic fluid before or during birth Dr Eastman and other obstetricians who conferred with us at Philadelphia told us that intra uterine anoxia does not at all regularly excite gasping respiratory movement in the human fetus.

The amniotic fluid theory was for these and other reasons left in a rather shaky status but no better contender was forthcoming to take its place Miller's belief that reduced function of the vagus nerve is characteristic of the neonatal period may well be true, but his suggestion that this results in membrane formation at that age was not considered beyond the stage of hypothesis.

"7 Clinically and pathologically there seems to be increasing evidence that many if not all of those infants whose lungs show membrane formation at death may have passed through a phase of relatively adequate pulmonary aeration and some through a phase of actual emphysema Dr Edith Potter prefers the term resorption atelectasis with hyaline-membrane to imply that the atelectasis is not primary

"8 The term hyaline membrane disease is being widely accepted and the belief that it can be clinically diagnosed has led to ideas as to methods of prevention and treatment. Prevention consists according to several in attempts at early and complete drainage of the upper air passages. Most conferees felt that this might be accomplished as well by prompt postural drainage as laryngoscopy and other more dramatic forms of removal. Also prevention of premature or complicated deliveries should reduce frequency of hyaline membrane formation.

"The clinical impression of effective treatment by providing high oxygen supersaturated with water or by the use of wetting agents such as sodium lauryl sulfate has not yet been substantiated To prove the effectiveness of therapy in a condition which can only be diagnosed by autopsy is in itself a baffling problem.

Dr Peter Gruenwald[1] at a Conference in New York on June 5 on the same subject pointed out the non specificity of the membrane and aptly remarked the hyaline membrane of premature babies may be eosinophilic herrings !

JOHN L EMERY

DEXTRAN SULPHATE

SIR,—The introduction by Dr Ricketts and his colleagues (Nov 14) of a synthetic heparin substitute is welcome, but it appears that the question of storage of the substance by the reticulo-endothelial system has not as yet been sufficiently studied. The authors seem satisfied that in case 8 post-mortem sections stained with toluidine blue showed no evidence of storage of material giving a metachromatic reaction. This, however is an unreliable method for demonstrating polysaccharides in tissues unless they are protein bound or otherwise rendered insoluble

In routine hospital practice fixation, mounting of sections and staining are all done in watery solutions, entailing extensive or complete loss of soluble polysaccharides. This possibly explains the failure to demonstrate storage of dextran sulphate in this case

Mowry and Millican,[2] by fixing tissues in and mounting sections from absolute alcohol, and staining by an alcoholic periodic acid—Schiff technique, were able to demonstrate injected dextran in the reticulo-endothelial cells of mice up to 8 months after injection. In view of this, it would seem advisable to re-examine the question using a similar method

The demonstration of storage of the drug would of course, indicate the most exhaustive experiments before it could be advocated for general use.

Chase Farm Hospital,
Enfield, Middlesex.

INCISION FOR ACUTE APPENDICITIS

Sir,—The article by Mr Ewing and Mr Monro (Oct 24) has undoubtedly, *pace* your contributor to In England Now, aroused the interest of a considerable number of your readers May I underline one or two of the points made and add a little to the discussion ?

All experienced abdominal surgeons, I feel, know the advantages of a McBurney's incision in the early case of acute appendicitis On the other hand, in the case where, from the symptoms and signs, one suspects a local or general peritonitis, particularly if the appendix is pelvic in position, the McBurney incision is inadequate and such an incision converted into a muscle-cutting one can be irritating to suture An immediate Rutherford Morison muscle-cutting incision is undoubtedly the better procedure, and, if sutured carefully, layer by layer, with interrupted sutures, heals no less satisfactorily

With regard to the question of drainage, where necessary, may I express admiration for Mr Donald's restraint (Nov 14), and agree entirely with what he says There is, however, no necessity to drain through the wound, a small stab incision between the lower end of the wound and the inguinal ligament, paying due regard to the presence and position of the circumflex iliac vessels, allows a drain to be inserted either down to the pelvis or behind the cæcum, thus achieving adequate drainage and allowing the main wound to heal undisturbed

Workington Infirmary, Cumberland IAN MacKENZIE

Sir,—The correspondence which has followed the article by Mr Ewing and Mr Monro has interested me greatly This is a most important subject

I have come to the conclusion, from routine examination of the abdomen at laparotomy and from 150 peritoneoscopy examinations, that adhesions to the posterior aspect of abdominal scars are the rule rather than the exception It is true they may become less in number with the greater use of non-absorbable suture materials

In a personal series of 65 consecutive operations for intestinal obstruction, 9 (14%) were due to adhesions to the posterior aspect of previous abdominal scars—4 midline, 2 Battle, 1 paramedian, 1 Mayo-Robson (trans-rectus), and 1 grid-iron Need I say more ? The grid-iron scar usually becomes adherent to the cæcum or omentum, seldom giving rise to trouble, whereas the more medially placed scars frequently become adherent to the small intestine

Whittington Hospital
London N 19

W W Davey

Sir,—I wish to add a few personal observations to the lively controversy aroused by Mr Ewing and Mr Monro

In regard to the age old feud between McBurney and Battle, I have, of course, seen herniæ follow both approaches, uncomplicated by clinical sepsis Perplexed as to its occurrence following the muscle splitting incision, I discovered that in two of these cases a "muscle split" had been converted into a "muscle cut' in a third some "cutting" was suggested by the unusually long scar and the mention in the notes of a 'high retrocæcal appendix" Two of the herniæ were inguinal in type

This result is hardly surprising If we agree that the anatomy textbooks are not infallible, then a 2 inch field near McBurney s point is all the more likely to overshadow a nerve The nerve will be displaced with the muscle fibres during the procedure of "splitting," but it will be incapable of stretching and will lie taut across the margin of the incision, where even the smallest cut could sever it

In Battle s approach it seems unkind to suggest that a nerve to the rectus muscle is often cut, but I think that nerve injury may be caused by excessive medial retraction of the muscle In this situation the nerves are rather small, and in the dissecting room I have avulsed them quite easily by medially retracting the rectus Conceivably, avulsion or ischæmic trauma may be similarly produced in the operating theatre

For the midline, paramedian, and Battle fans, I suggest the modified Battle approach In this the anterior wall of the rectus sheath is divided in the line of its fibres in its lateral $^{1}/_{2}$ inch or less, and this incision is extended into the conjoined tendon of the abdominal muscles, lateral to the sheath, for an inch or more Medial retraction of the rectus muscle is slight

This incision, when properly made, is physiologically sound and allows early ambulation, it can be widely extended laterally, it respects the nerves, and it is capable of providing an almost avascular approach And a crease incision, carefully sutured, can be as inconspicuous as any Pfannenstiel after a few months, and it avoids the sustained and devitalising retraction which the latter incision inevitably entails

London, W 2 W H Radley

CORTISONE AND RHEUMATOID ARTHRITIS

Sir,—The letter by Dr Copeman and Dr Savage (Oct 17) reveals the disparity between the earlier hopes and the present estimate of the value of cortisone in rheumatoid arthritis The *fact is that there* is no shortcut to the cure of this disease, but that any results of permanent value can only be obtained slowly

Cortisone therapy, at great expense in material and clinical care, can produce in some patients an initial temporary response, but it is impossible or impracticable to continue such treatment on a large scale for an indefinite time, not only because of the cost, but also because of the undesirable side effects arising from its continued use

If, however, this temporary benefit could be linked with the effect of some other more slowly acting remedy, which could be given for life if need be, there might be some justification for the initial use of cortisone in selected cases Such a remedy exists in the use of an extract of intestinal mucosa, containing as its active agent the group of enzymes known generically as "erepsin"

May I refer your readers to two articles by me on the use of such an extract ?[1] [2] In the second paper I recalled that, of a series of untreated cases of rheumatoid arthritis observed over many years in America, 38% were improved, 15% were in remission, 13% were unchanged, and 34% were worse Taking all my rheumatic cases together, in 1000 cases treated with intestinal extract and observed over a long period, the results were 497 (49 7%) much improved, 407 (40·7%) improved, 89 (8 9%) not improved, and 7 (0 7%) worse. This series included patients who could be regarded as almost hopeless at the outset and who had had a variety of treatments over many years

I do not think that the present intestinal extract that I use is the best which can be obtained, but it does represent a compromise between cost and efficiency, and efforts are being made to improve it The average cost per patient per annum is in the region of £10 for treatment with intestinal extract, and the treatment does not involve much of the doctor's time—an important point in dealing with such a common disease Can Dr Copeman and Dr Savage give us any idea what the average cost of cortisone is likely to be ?

For those who wish to use cortisone in the initial stages I suggest that it might be combined with treatment with an intestinal extract, withdrawing the former as soon as possible but continuing the latter In this event sedatives should be eliminated or reduced to the very minimum so as to allow for an adequate withdrawal of any sedative effect on the secretory activity of the patient's own intestinal mucosa.

One of the most significant facts emerging from the long continued use of an intestinal extract in correct doses, is a slow but extraordinary improvement in the general health of the patient, as well as the slow but definite improvement in the rheumatic condition. After a year or two of treatment many of these patients look five or more years younger and have far more energy

---

[1] *Ann rheumat Dis* 1947, 6, 15
[2] *Med Pr* 1953, 229 444

After over twelve years' use of this preparation I am satisfied that it has enabled me to do more good to more patients than any other remedy I have known.

Manchester. ARNOLD RENSHAW

GOOD SENSE ABOUT ANTIBIOTICS

SIR,—We have read, rather belatedly, your annotation of April 25 and although we have not had the opportunity to see the United Bristol Hospitals booklet we do believe that this should be widely circulated.

May we raise a query, however, which seems to be relevant. Although we have made a preliminary survey of the literature covering *the topic of the sensitivity* tests which are suggested for the sulphonamides, we have not yet been able to find a simple method which is satisfactory. On the contrary, some of the methods suggested do not fill the essential requirement of offering any appraisement of the relative activity of the sulphonamides at pH 7·4, which seems to us to be important.

and Dispensary, Wigan.

CORONARY HEART-DISEASE IN TRANSPORT WORKERS

SIR,—The statistical analysis by Dr Morris and his colleagues (Nov 21), revealing the different patterns of coronary disease in drivers and conductors, and their different morbidity rates, is surely of great significance.

But I am not at all happy with the authors' assumption that physical activity is a protecting factor for the conductors. One might equally well argue that the mental stress of having constantly to make split-second decisions, involving the possibility of immediate demise not only of himself but of many of his passengers also, is a greater mental stress for the driver than any imposed on the conductor. One can imagine that the secretion of adrenaline among drivers may at times reach very high levels.

It would also be interesting to know how many drivers start their careers as conductors—and how long a driver has been driving.

I well remember twenty years ago discussing the aetiology of coronary disease with a senior member of the profession, and his remark: "I am not so sure the motor-car hasn't something to do with it."

London, W 1 DOUGLAS ROBERTSON

DIARRHŒA AFTER GASTRECTOMY

SIR,—In the case we reported on Sept 19 the patient was stated to have "received water only by mouth and 5% dextrose intravenously." This was a correct factual report. Mr Grant (Nov 21) distorts the facts to fit his theory. He then complains that the literature is confused. What better way of confounding thought and barring progress is there than this?

The assumption that hypertonic dextrose saline solution is generally used is probably now incorrect. At least in this hospital care is taken to give an isotonic solution (4% dextrose in 1/5th normal saline). With this there seems to be much less trouble with venous thrombosis than when 5% dextrose is used.

J E RICHARDSON
D W VERE

Surgical Unit
London Hospital, E 1

SIR,—The diarrhœa following gastrectomy described by Mr Williams and Mr Pullan (Nov 14) develops on the second and third postoperative days. During this period there are definite metabolic changes including a loss of potassium, which in some cases may be severe. In studying cases of hypokalæmia, I have quite often observed diarrhœa which has definitely been secondary to potassium depletion. In fact in some cases the occurrence of diarrhœa has been the first indication of inadequate therapy.

Following gastrectomy one patient developed severe diarrhœa on the fourth postoperative day, and this continued for three days, when the condition became critical. 4 g of potassium chloride was then given intravenously, followed by oral therapy. The diarrhœa ceased within 24 hours of starting potassium therapy.

I suggest that the origin of diarrhœa in postoperative cases may be metabolic in nature and that it may possibly be avoided by maintaining a normal potassium balance as advocated by Ebrill and Naftalin[1] in your columns.

Biochemist.

Edgware General Hospital.

TELEVISION AND THE FAMILY

SIR,—Your note last week reviewing our report on Television and the Family suggests that, as the findings of my class are warmly in favour of this form of entertainment, it seems just possible that we are keen televiewers. I can state for myself that I have neither a television set nor do I have a frequent opportunity of viewing. Only two members of my class have television sets. This fact has in no way influenced our findings.

Cheylesmore, Coventry MAX GORDON

Obituary

LANCELOT EDWARD BARRINGTON WARD

K.C.V.O., Ch.M. Edin., F.R.C.S., F.R.C.S.E.

Sir Lancelot Barrington Ward, surgeon to King George VI and since 1952 to the Queen, and consulting surgeon to The Hospital for Sick Children, Great Ormond Street, died at his Suffolk home on Nov 17.

He was born in 1884 at Worcester, the second of the five able sons of the late Canon M. J. Barrington Ward, D.D. Later the family moved to the rectory of Duloe in Cornwall, whence had emanated much of the familiar *Liddell and Scott* Greek lexicon, and in this appropriate environment they grew up nurtured in the classical tradition. Barrington Ward himself was a classical scholar, first at Westminster School, where his health was troublesome, and then at Bromsgrove School, which agreed with him well. Later he gained a classical exhibition at Worcester College, Oxford. Throughout his life his classical education was shown in a masterly command of word and phrase and a handwriting of rare neatness and precision.

[Press Portrait Bureau

But in the end he chose medicine and Edinburgh. As a student he was distinguished not only for the honours degree which he took in 1908 but by his prowess at rugby football. As one of the lightest but certainly one of the best of forwards he was awarded four English international caps. In 1910 he took his Edinburgh fellowship, and the English fellowship two years later. In 1913 he proceeded to the Ch.M. with honours and was awarded the Chiene medal.

His London career began with his appointment in 1910 as a house-surgeon at Great Ormond Street. He was fortunate in the moment of his coming. Under the inspiring leadership of the late George E. Waugh and H. A. T. (now Sir Thomas) Fairbank, the surgery of childhood was arousing interest and study, and Great Ormond Street was attracting young surgeons to the child as well as his fascinating surgical p

---

1 Ebrill D, Naftalin, L. *Lancet*, Aug 29 1953

made a peculiar appeal Of such emphatically was Barrington-Ward After his house-surgeoncy he became resident medical superintendent This post, which no longer exists, brought both medical and surgical responsibilities, and was designed to give the holder the comprehensive outlook essential to a children's surgeon In 1914 he was elected honorary surgeon, and appointments to the staffs of the Royal Northern and Wood Green Hospitals soon followed, which offered him full scope for his practice in adults In the development of these two busy and enterprising hospitals he later played a leading part

Soon after the outbreak of war in 1914 he joined for a short time Lady Wimborne's hospital in Serbia On this venture he found meagre scope for his surgical abilities, but he was awarded the Grand Cross of the Order of St Olave and St Sava for his work The experience intensified his abhorrence of war and its wastage, though he later regretted his abstention from the Services

On his return to London responsibilities multiplied apace and the pattern of his busy and successful future was soon established He accomplished a prodigious volume of work, for he was scrupulously loyal to his hospital obligations despite the demands of a widespread and exacting private practice To both he gave his unstinting best, and he got through it all only by care and punctuality in organisation, an unhurried celerity of execution, and a tough physique But he had scanty leisure even for essential rest and recreation, and his contributions to medical journals, though always admirable, were relatively few He did, however, find time in his earlier years to write his classic *Abdominal Surgery for Children* and later he edited the *Royal Northern Operative Surgery* He also contributed to *Garrod, Batten, and Thursfield* and *Hutchison's Index of Treatment* Last year he delivered at the Royal College of Surgeons a masterly Hunterian lecture on Swellings of the Neck in Children He was a past president of the section of pædiatrics of the Royal Society of Medicine, and he was a former president of the Surrey Agricultural Association

In 1918 he operated for appendicitis on the then Prince Albert, and for his services to the Royal Family he was created K C V O in 1935 In 1936 he was appointed surgeon to King George VI, and later he became extra surgeon to H M the Queen.

T T H writes "In the residency of the Edinburgh Royal Infirmary it is—or was—the custom for each house-physician and house-surgeon to record his passage by carving his name on the dining-table On this famous table under the year 1910, among a notable group, stands the name of L E Barrington-Ward In this sign-manual the discerning eye may detect much of the past, present, and future of this young man The carving is in large and conspicuous characters, neat and decisive Even in 1910 one could have surmised a classical training, a hand endowed with no mean dexterity and orderliness of execution, a mind confident and assured, and a personality not unduly modest or retiring The prognosis deducible from that provocative piece of wood-carving has been amply verified Barrington-Ward's natural aptitude for his chosen craft was developed and perfected with assiduous application, and this through the best of all schools of training in gentleness of manipulation and delicacy of touch—children's surgery

"His strength of character was manifested in unwavering confidence in his own ability and in an irrepressible optimism He set himself the highest standard not only in work but in living, nor ever doubted its attainment He accepted good fortune and recognition as his natural and inevitable due and discounted the rest But competence and self-assurance would not alone have brought him that full measure of trust, respect, and affection which were assuredly his Lance, or, if one must be more formal, 'B-W,' was blessed with a magnetic personality Handsome and debonair, courteous and kindly, he invited confidences and inspired instinctive trust His colleagues inevitably turned to him in any personal or family surgical crisis—and how many of us have cause to be grateful to his skill His judgment was as sound as his hands were deft and gentle His equanimity was proof against all the stresses and strains of a surgeon's life, and in the lesser turmoil of committees he was equally imperturbable This quality, along with his wisdom and diplomacy, put him into many committee chairs, and greatly increased the burden of his work

"His home life was always happy and gracious. His tastes were fastidious, he lived generously and always welcomed and entertained his friends genially Yet there was in his general demeanour a dignified, self-contained reserve which was not lightly dispelled, when it was, his friendship was warm, wholehearted, and unassailable For those of us who enjoyed his friendship life can never be quite the same without him He had seemed so enduring and unageing that we cannot but deem his death untimely"

Sir Lancelot married in 1917 Miss Dorothy Anne Miles, who died in 1935, leaving him with three daughters. In 1941 he married as his second wife Miss Catherine Reuter who, with their son, survives him

BERNARD CONSTABLE MAYBURY

M B Lond, F R C S

Mr Maybury, consulting surgeon to St Thomas's Hospital, died on Nov 15 at the age of 65 He was one of the few remaining general surgeons, and his craftsmanship was backed by a profound knowledge of medicine In temperament and outlook he had many of the qualities of the physician

Marcus Adams

The third son of Dr A. V Maybury of Portsmouth, he was educated at Epsom College and St. Thomas's Hospital, and as a student he took almost every prize and medal open to him He was bracketed equal for the scholarship in anatomy in the intermediate examination for the London M B, and he won the Musgrove scholarship and the Cheselden and Treasurer's gold medals at St Thomas's After qualifying in 1909 and graduating M B with honours in surgery in 1910, he held some half-dozen house-appointments at St Thomas's, including that of surgical registrar to Sir George Makins who, with Sir Cuthbert Wallace, became an outstanding influence in his life In 1913 he took the F R C S and was appointed resident assistant surgeon at St Thomas's

The war interrupted his work in London, but during his service as a surgeon at No 9 casualty-clearing station in France and Italy he gained much experience and made many friends It was there work, too, which stimulated his interest in vascular injuries On his return to St Thomas's after the war he was appointed to the staff The new surgical unit had then lately been started under the direction of Sir Cuthbert Wallace, who picked Maybury as the man he needed to work with him Maybury was accordingly appointed deputy director and in due course became surgeon to the hospital, holding his post until February 1948, when he retired on reaching the age of 60 Four months after he left, the retiring age was raised to 65, and everyone at St Thomas's regretted that he, and they, had missed these extra five years

"Maybury was one of those intelligent and efficient people," writes C M P, "who do their work in life with the minimum of self-advertisement He was naturally a self-effacing and reticent man, and I think his close association in work with Sir George Makins and Sir Cuthbert Wallace developed his conservative but critical attitude towards surgical problems He lacked the vigour of body which is often so important an asset to the successful surgeon, but, though plagued by migraine he possessed a toughness of fibre and strong sense of public duty which enabled him to continue work at full pressure until quite recently He was naturally a neat operator and his mastery of the technique of abdominal surgery was recognised by his colleagues from the time of his casualty work in France till his full maturity at

t. Thomas's. His clinical judgment was admirable, nd, though I do not think he was either a successful or popular teacher for the average student, the more dvanced and postgraduate men appreciated his work nd his counsel and many of his patients were to be ound among doctors and their relatives He was not a ood committee-man, but when a matter which concerned im was under discussion, he could be strong and determined in opposition He wrote seldom and then generally nly under pressure from outside His rare contributions o surgical debate were characterised by a full and uthoritative knowledge of the subject at issue. By his assing we lose one of the few remaining generally quipped surgeons of the past era.

R H. O B R, who, after the 1914–18 war, was ppointed the first house-surgeon to the new surgical nit at St. Thomas's, describes Wallace and Maybury as n some ways very similar men They were both ntensely interested in the academic side of surgery nd had an almost morbid dislike of any form of self dvertisement, feeling strongly that there were so many tupid things said by loud mouthed people that it was ll-advised to write or speak until something of importance ould be said This was partly attributable to an innate hyness in both men and because of this they were both ifficult men to get to know well This is the reason why Maybury was not as well known as his merits entitled him to be.

"He was in my opinion the almost perfect surgeon in that he combined in equal measure academic knowledge, nique diagnostic ability, and fine technical achievement Among Thomas's men he was rightly regarded as the most valuable surgical counsellor He was also a magnificent critic and could be guaranteed to see any problem in its right proportions. He published comparatively little but what he did publish was of the highest order Not a strong man physically, he was persistently dogged by ill health which undoubtedly made his task harder He will be remembered as one of the greatest surgeons that Thomas's has produced "

Mr Maybury married in 1930 Isobel Wilson, the daughter of Mr George Lyall, J P She survives him with a son and a daughter

FRANK GEOFFREY HOLMAN
O B E., M.R.C.S

Dr Geoffrey Holman, chief medical officer of the North Thames Gas Board died on Oct. 23 at the age of 44 After qualifying from Guy's Hospital in 1933 he joined the century-old practice of his family in Hampstead. On the outbreak of war he was posted abroad with the R.A.M.C., and most of his war service was spent with field ambulances in Dunkirk, Madagascar, India, and Italy; members of 141st field ambulance will remember him as a shrewd and kindly officer He was promoted to the rank of lieut.-colonel and later he was appointed O.B.E. After the war he did not return to general practice but joined the staff of the North Thames Gas Board, where his sound judgment, unselfish work and genuine interest in people won the respect and affection of his colleagues and patients alike

5.30 P.M. Prof. C. A. Keele Hyperhidrosis.

WEST END HOSPITAL FOR NERVOUS DISEASES, 10 Marylebone Lane, W 1
4.30 P.M Dr Gerald Parsons-Smith: Neurological demonstration.

Wednesday 2nd

ROYAL SOCIETY OF MEDICINE
4.15 P.M. *Section of History of Medicine.* Dr Charles Burns: A Forgotten Psychiatrist—Baron Ernst von Feuchtersleben M.D (1833). Prof. F Wood Jones Strange Career of an Anatomist.
8 P.M. *Section of Surgery* Mr F J Gillingham, Mr W S. Lewin, Miss D J Beck: Head Injuries in Civil Practice

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE 28 Portland Place, W 1
3.45 P.M. Sir Harold Whittingham Hygiene and Sanitation in Aviation.

INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr H. Haber Bullous Eruptions of Skin.

INSTITUTE OF UROLOGY, 10 Henrietta Street, W C 2
5 P.M. Mr F R. Kilpatrick Tuberculosis of Renal Tract.

MANCHESTER MEDICAL SOCIETY
4.30 P.M. (Medical School University of Manchester) *Section of Medicine.* Dr A. Morgan Jones: Coronary Disease.

MIDLAND MEDICAL SOCIETY
8.15 P.M (151 Great Charles Street, Birmingham 3) Mr Lawrence Abel: Present Position of Cancer Problem.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH
8.30 P.M. (Royal College of Surgeons, Nicolson Street.) Dr J P Stewart, Dr M. Z. Kawa: Further Observations on Effect of Cortisone and A.C.T H in Treatment of Allergic Rhinitis.

Thursday 3rd

BRITISH POSTGRADUATE MEDICAL FEDERATION
5.30 P.M. (London School of Hygiene and Tropical Medicine.) Dr R. M B. MacKenna Scientific Approach to Dermatology

ROYAL SOCIETY OF MEDICINE
5 P.M. *Section of United Services.* Group-Captain R. L. Soper Air Transport of Poliomyelitis Cases in Mechanical Respirators. Squadron Leader C. B. Wynn Parry: Aspects of Rehabilitation in Royal Air Force.
8 P.M. *Sections of Neurology and Paediatrics.* Mr G I. Scott, Mr J H Doggart, Dr S P Meadows, Dr J G Greenfield: Neuro-ophthalmological Aspects of Failure of Vision in Children

INSTITUTE OF LARYNGOLOGY AND OTOLOGY
5.30 P.M (Royal College of Surgeons, Lincoln's Inn Fields, W C.2) Dr Michael Ward: Ascent of Mount Everest—Medical Problems

CHADWICK LECTURE
5 P.M. (Wright Fleming Institute, St. Mary's Hospital, Paddington W 2) Prof. B W Windeyer: Radiotherapy in its Relation to Dermatology (Malcolm Morris lecture.)

LIVERPOOL MEDICAL INSTITUTION 114 Mount Pleasant, Liverpool, 3
8 P.M Symposium on Pathology of Tuberculosis.

Friday 4th

POSTGRADUATE MEDICAL SCHOOL OF LONDON
4 P.M. Dr R. G Macfarlane Marrow Puncture

ROYAL SOCIETY OF MEDICINE
10.30 A.M. *Section of Otology* Mr Kenneth Harrison Ramsay Hunt Syndrome.
3 P.M. (Royal College of Surgeons, Lincoln's Inn Fields, W C.2.) *Section of Laryngology* Mr Munro Black, Dr B T Davies: Keratoses of the Larynx.
5 30 P.M. *Section of Anaesthetics.* Dr A. J W Beard Antihistamines in Anaesthesia. Dr A. A Juvenelle: Experiments with Deep Hypothermia. Dr D G Melrose Applications of Heart lung Machine in Man.

INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr R. T Brain: Diseases of Children.

HEBERDEN SOCIETY
3.30 P.M. (Royal College of Surgeons.) Sir Russell Brain, P.R.C.P Spondylosis—the Known and the Unknown. (Heberden oration.)

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY Whipps Cross Hospital E.11

MIDLAND TUBERCULOSIS SOCIETY
8 15 P.M. (151 Great Charles Street, Birmingham 3) Prof T Pilcher Bronchiectasis in Children.

Notes and News

SMOKE ABATEMENT

SPEAKING in Manchester on Nov 23, Mr Arnold Marsh, general secretary of the National Smoke Abatement Society, said that for many years a patient, guerilla like campaign against smoke had been waged by a handful of partisans Now, because of last December's tragedy in London, a full-scale counter attack was in train, and although the partisans were still few they were at least being encouraged by a public that had suddenly become aware of the deadly enemy in their midst Such a great surge of public interest could, however, create its own difficulties, and two important factors were in danger of being overlooked. First, the occasional lethal smog is probably less damaging in its effects and cost than the normal smokiness of the atmosphere, which insidiously undermines health Secondly, though sulphur dioxide is certainly the most acid and corrosive part of the pollution, the smoke in itself affects the health of town dwellers by screening them from the sun In the winter months up to two thirds of a city's natural light may be cut off by the overhanging pall of smoke Though it must take a long time to get rid of even a part of the sulphur dioxide, to get rid of smoke alone, which could be done quite soon, would reduce the dangers and costs of air pollution to a fraction of what we now experience Meanwhile, Mr Marsh added, the smoke abatement movement is still struggling along on a shoestring "I sometimes wonder, when vast sums are being raised, or are coming out of taxes, to restore some famous building from the ravages of smoke, whether a small percentage—just a crumb—might not also be devoted to efforts to stop it from happening again "

SCOTTISH HOSPITAL ENDOWMENTS

THE Scottish Hospital Endowments Commission, presided over by Sir Sydney Smith, have issued a memorandum describing the principles on which they propose to distribute the £13 million of endowments to hospitals in Scotland. They propose that every hospital board of management in Scotland should have at least £2 per bed a year to provide for patients and staff amenities, such as additional furnishings and wireless sets, which cannot always be charged to the National Health Service Where a board of management has at present no endowments or insufficient endowments, the commission will transfer funds to it from other boards in the same general area Each board will be left free to perpetuate by name any endowments which it considers should be commemorated A few endowments, the commission think, should be retained for specific purposes, such as funds for nurses' prizes.

Where a board has sufficiently large endowments the commission will transfer part to the Scottish Hospital Endowments Research Trust set up this year by the Hospital Endowments (Scotland) This Act allows for the transfer of endowments to provide the Trust with an income of up to £120,000 a year to further medical research. Boards are also free to use their endowment funds for research

CLINICAL ORTHOPÆDICS

IN the first issue of a new periodical, *Clinical Orthopædics,*[1] the editor in-chief, Dr A F De Palma, says "Most of us are keenly aware of the need for additional outlets for material of orthopædic interest , also, it is generally known that the existing journals are swamped with good material which because of the lack of space is denied publication In addition, the English speaking countries do not have an organ capable of providing avenues of expression for the ever increasing subdivisions of orthopædic surgery and the allied specialities Finally, no concerted efforts have been made by the orthopædic group as a whole to keep the general practitioner and the surgeon in allied fields abreast of the rapidly growing scope of orthopædic surgery " His object therefore is to carry the news "not only to orthopædic surgeons and traumatic surgeons, but also to all those in the allied specialities and above all, to the general practitioner "

Surprisingly enough, the first issue is a book of nearly 250 pages including a 12 page index which seems unnecessarily detailed for what sets out to be a journal The plan is to publish two volumes a year, each divided into two parts. The first part is to be devoted to a single subject (the first issue deals with some problems of orthopædics in children); and the second will contain miscellaneous articles.

These objects are impressive in their scope, and are apparently intended to appeal to a wide range of doctors But, in this country at any rate, few general practitioners would have the time or inclination to read such an extensive publication, much of which is of no practical interest or value to them Moreover, much of what is intended for the general practitioner is of no great interest to the orthopædic surgeon, it is more on the lines of what is being done so well already in this country in the various types of refresher course Nevertheless, tastes differ, and it may well be that in the United States the general practitioner is expected to have a more detailed knowledge of the practical and theoretical aspects of orthopædics

The standard of the articles in the opening volume is on the whole high. In the first section most of the articles are written for general practitioners, and it may be questioned whether it helps them to read more than one article on the same subject, particularly when these give conflicting viewpoints which are really only the concern of the specialist. But, whatever the verdict of the general practitioner, the orthopædic surgeon will find plenty to interest him.

A JOINT BED BUREAU

WHEN the National Health Service was started almost all the mental deficiency hospitals which had been administered by the Lancashire Mental Hospitals Board to provide for the needs of Lancashire and Cheshire and the county boroughs fell within the Manchester Regional Hospital Board area. The result has been that the Manchester board have over 6000 beds for mentally defective patients and the Liverpool Board a little more than 600 In 1948, many patients in the institutions in the Manchester region had been admitted from the Liverpool region and during the past five years the Manchester board have continued to place beds at the disposal of the Liverpool board It has now been agreed that all applications for the admission of mentally defective patients from local authorities within the areas of both boards will be referred to a joint bed bureau at the offices of the Manchester board The bed bureau will maintain waiting lists of patients and the priority for admission will be determined by collaboration between Dr G R Pile, regional adviser in mental deficiency to the Manchester board, and Dr N Fraser MacKenzie, regional adviser to the Liverpool board In this way, as suitable vacancies arise, patients will be admitted in accordance with their needs and it will be possible for the boards to give assurance that the most urgent cases will receive the earliest attention

TUBERCULOSIS IN DECLINE

EVERY second that passes converts live truth into dead history, and we all know that history is more a matter of opinion than of fact Just now we are watching a decline in the death rate from tuberculosis, and it is pleasant to believe that medicine and public health have had some hand in bringing it down. Yet as Dr Iago Galdston recalled last year,[1] the decline began in the first half of the nineteenth century, long before we knew anything about the tubercle bacillus, or took any special measures against it, and he quoted the remark of René J Dubos, made in 1951, that "Neither the discovery of the tubercle bacillus, nor the growth of the sanatorium movement, nor the organisation of the antituberculous associations, nor the introduction of pneumothorax therapy, seem to have affected markedly the shape of the curve." Moreover, the mortality from some other diseases—notably pneumococcal pneumonia, bronchitis, Bright's disease, scarlet fever, and measles—has also declined since the same date, which led Brownlee to conclude that "a considerable part of the decline of tuberculosis in recent years is in line with the biological properties of disease in general, and has little to do with hygienic conditions "

But there are good grounds for distrusting these gloomy opinions about the history of tuberculosis, as Dr Galdston points out It may be true that tuberculosis has had its ups and downs in the past, and that we are fortunate to be coinciding with a down, but the curve is too general to take account of those minor deviations from the mean in which circumstances seem, for good or ill, to have taken a part. Thus, Negroes are particularly susceptible to tuberculosis, ut in Charleston, South Carolina, between 1822 and 1830, the mortality rate for both Whites and Negroes, though high—round about 450 per 100,000 living—was equal. By 1865–74 after the Civil War when the freed Negroes suffered sorely from want, the rate for Whites had fallen to 200, but that for Negroes remained at over 400 During the succeeding decades the rate for Whites remained fairly steady while the rate for Negroes rose until in 1900 it was 675 Again in New York in 1950, when the tuberculosis death rate for Whites was 22, and the case-rate 80 per 100 000 population, the comparable rates in Harlem, the Negro quarter were 361 and 109 In the heart of this congested area the rates were even higher: 470 and 153. Thus if we cannot speak authoritatively of the effect of public-health measures and better housing on the downs of tuberculosis, we can be confident that the lack of them affects the ups : as Dr Galdston says, We know that misery deprivation poverty overwork, always have been reflected in a rise of the tuberculosis mortality He argues that tuberculosis is primarily a state of being and only derivatively a disease. The tubercle bacillus is always with us, but whether it can prevail against man and produce disease or remain in some form of symbiotic balance depends on man s state of being—which in turn depends on man s own knowledge awareness, conscience and wisdom—how in a word, he manages his social and individual affairs.

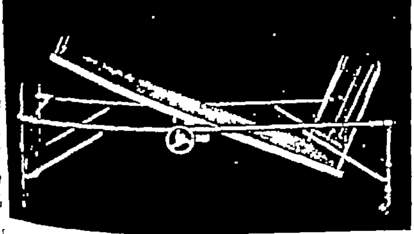
[1] On the Epidemiology of Tuberculosis Lecture to the Michigan Tuberculosis Association, June, 1952 A Christmas Seal Publication. Pp 16

In the last few years our knowledge has been widened by the discovery of new drugs, and we have seen a rapid decline in mortality from tuberculosis, not only in Great Britain but all over the world. Yet as the annual report for 1952–53 [2] of the National Association for the Prevention of Tuberculosis puts it we are really interested more in lives than deaths and there is no evidence that the incidence of fresh cases of tuberculosis is declining—rather the reverse In England and Wales we are still getting some 45 000 new cases a year The N.A.P T being deeply concerned with the preventive ideal, has contributed to publicity for mass-radiography issued leaflets about B C G., published material of interest to doctors in the *N.A.P T Bulletin*, arranged exchange scholarships for doctors from overseas, organised conferences on various aspects of tuberculosis work, provided scholarships to tuberculosis nurses wishing to train for the post of nurse teacher financed investigations into reablement programmes, kept touch with interested people and fellow organisations in the Commonwealth, and distributed much propaganda The funds for this work come largely from the sale of the N.A.P T Christmas seals, which are now so well known as to need no introduction This year the coloured design shows a horn of plenty spilling gifts; and the N A.P T in expectation of a record sale of seals, have printed 100 million of them. At $^1/_2d$ each they have already raised hundreds of thousands of pounds for this good cause They can be bought in sheets of 100 at 4s (which means there are 4 thrown in for luck) and there are also Christmas cards in two designs at 6s a dozen. Both may be had from the Duchess of Portland chairman, N.A.P T Tavistock House North, London, W C 1

NEW TILTING BED

THE Sidhil Dewhurst bed, illustrated here, is intended for postural drainage With it, greater tilt is possible than with blocks under the feet at one end and the centre of gravity is not raised as it is with blocks. The tilting device, which works on a quadrant-and worm arrangement, is easily operated. The bed is held stationary by two wood stump feet at the foot end It has been designed by Mr Harry Dewhurst, supplies officer of the Burnley and district hospital group in association with the manufacturers, Messrs. Siddall & Hilton Ltd. Centre Mills, Sowerby Bridge, Yorkshire



University of Cambridge

On Nov 14 the following degrees were conferred:

M.A —F W Campbell.
M.B B Chir — R. J Hutchinson.
* By proxy

University of London

The title of reader in entomology as applied to hygiene has been conferred on Mr J R Busvine D.SC., in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

University of Leeds

Dr D G F Harriman has been appointed lecturer in neuropathology in the department of pathology

University of Sheffield

Dr T J Rendle-Short has been appointed lecturer in child health Dr K S. Holt tutor in child health, and Dr D H Anderson part-time clinical teacher in chest diseases

Dr Irving Gordon, of the New York State Department of Health, has been appointed a visiting senior lecturer in bacteriology during his visit to the university this session

University of Birmingham

The university is appealing for £500 000 which is needed during the next seven years for research and education Last year the annual costs were £1$^1/_4$ million towards which the Government gave £800 000 and endowment and other resources are not enough to bridge the gap

In supporting the appeal Dr A. P Thomson vice-principal of the university cited as examples of research that might be held up for lack of funds, work on a substitute for blood needed for transfusions the investigation by chemical dissection of the brain, of breakdowns in workers caused by nervous stress, and the causes of morbidity Money is also needed for building.

Royal College of Surgeons in Ireland

On Nov 20 the following were admitted to the fellowship:

E. G Leahy and Alexander McCallister

Society of Apothecaries of London

Dr H. Seaward Morley master presided at a recent meeting of the court of assistants at which Dr J P Hedley was reappointed as the society's representative on the General Medical Council

The following were elected to the livery:

[2] Leadership Against Tuberculosis. N A.P T., Tavistock House North, Tavistock Square London, W C.1 Pp 64

Middlesex Hospital

Prof Brian Windeyer has been appointed dean of the medical school in succession to Sir Harold Boldero, who will retire next year after holding office for 20 years.

Heberden Society

Sir Russell Brain, P.R.C.P., will deliver the Heberden oration on Friday, Dec 4, at 3 30 P.M., at the Royal College of Surgeons, Lincoln's Inn Fields, W C 2 He is to speak on Spondylosis—the Known and the Unknown

Journal of Embryology and Experimental Morphology

The annual meeting of the editorial board of this journal will be accompanied by public scientific sessions at which papers by members of the board will be read and discussed These will be held in the department of anatomy, University College, Gower Street, London, W C 1

The Young Worker

The department of education of the University of Oxford is holding a conference at Manchester College, Oxford, from April 3 to 9, on the Young Worker Education for Human Relations Further particulars may be had from the conference secretary of the department, 15, Norham Gardens, Oxford

Tuberculosis Educational Institute

Clinical courses for doctors will be held at Sully Hospital, Glamorgan (Jan. 20–21), at King George V Hospital for Diseases of the Chest, Godalming (March 3–5 and Sept 29–Oct 1), Red Cross Sanatoria of Scotland (April 7–9), Cheshire Joint Sanatorium, Market Drayton, Salop (April 28–30 and Oct. 27–29) Further information may be had from the secretary of the institute, Tavistock House North, Tavistock Square, London, W C 1

Absent from School

At a Nottingham court on Nov 17 parents who had been summoned for not sending their children to school alleged that their doctor had refused to issue medical certificates for sickness An education department officer explained that the case was not an isolated one Doctors who withheld certificates usually advised the parents to tell education officials to contact the doctor if there were any inquiries But there were 47,000 children in the city Some were away every day, and the department could not keep interrupting a doctor's busy surgery

Centre for Spastic Children

Under the sponsorship of the No 4 (Chelsea) Group Hospital Management Committee a day centre for spastic children under the age of five or six is to be opened in part of the Cheyne Hospital for Children, Cheyne Walk. To begin with about 24 children will be taken, but it is hoped to expand the work later In the meantime a group of people, called the Friends of the Spastic Centre, have been formed Those who are interested are asked to attend a meeting at the Chenil Galleries, King's Road, Chelsea, on Monday, Dec 7, at 3 P.M.

Society of Chemical Industry

At the next meeting of the microbiology group of this society to be held on Thursday, Dec 3, at 6 15 P.M., at 11, Chandos Street, London, W 1, Prof M Stacey, F.R.S., Mr A E James, Dr F Fletcher, Mr A R Lockwood, and Mr A. W Wilkinson, F.R.C.S., will deliver papers on Dextran

The society's food group (nutrition panel) is to hold the second meeting of its series on Nutritional Reappraisals on Wednesday, Dec 9, at 11, Chandos Street, London, W 1, at 6 30 P.M., when Dr R Passmore will speak on Some Recent Investigations of Human Calorie Requirements

Half a Bus

The physiotherapy department of Wolverhampton Royal Hospital has installed half a bus, complete with staircase, on which patients may practise getting up and down stairs and accustom themselves to normal travelling

Films on Psychology and Psychiatry

The Scientific Film Association has published a catalogue of 107 films on psychology available in this country The catalogue is divided into the following sections developmental psychology, educational psychology, testing techniques, industrial and applied psychology, animal and experimental psychology, abnormal psychology and psychiatry, and juvenile delinquency Copies may be had (7*s* 6*d*. plus 7*d* postage) from the association, 164, Shaftesbury Avenue, London, W C 2

World Veterans Federation

The rehabilitation peace prize of this federation has been awarded to Dr Ludwig Guttmann, director of the spinal injuries centre at the Ministry of Pensions Hospital, Stoke Mandeville, Bucks

Assay and Detection of Pyrogens

A symposium on this subject is to be held by the Pharmaceutical Society and the biological methods group of the Society of Public Analysts at 2 30 P.M. on Friday, Dec. 11, at University College, Gower Street, London, W C 1 The symposium is open to all who are interested in the subject, and summaries of the papers may be had from Mr K. R. Capper, editor of scientific publications of the Pharmaceutical Society, 17, Bloomsbury Square, W C 1

Multiple Sclerosis Society

The inaugural meeting of this society was held in London on Nov 18 The chief aim of the society is to help patients with this disease to be useful citizens rather than invalids. Members of the society will visit patients to give advice, companionship, and, when necessary, financial help Local groups of the society are to be formed, and further particulars may be had from the secretary of the society, 9, Grosvenor Crescent, London, S W 1

Medical Memorials

On Nov 7 a new outpatient department at Trowbridge and District Hospital was formally opened as a memorial to John Levis, consulting surgeon to the hospital from 1919 until his death in 1943

A plaque in memory of Alexander Mitchell, consulting orthopædic surgeon to Aberdeen Royal Hospital, has been unveiled at Fyvie Cottage Hospital, Aberdeenshire.

Medical Training in the East

The governments of Malaya and Singapore have appointed a committee to inquire into " the future needs of university medical education, including education in dentistry and pharmacy, in Singapore, the Federation of Malaya, and Borneo, and to advise on the provision and siting of the facilities necessary to meet those needs " The members of the committee, Sir David Lindsay Keir (chairman), master of Balliol College, Oxford, Dr J H Biggart, professor of pathology and dean of the faculty of medicine, Queen's University, Belfast, and Mr T P Kilner, Nuffield professor of plastic surgery in the University of Oxford, leave by air for Singapore on Nov 22

CORRIGENDUM *Myxomatosis*—In our annotation (Nov 14 p 1031) we said that hundreds of millions of rabbits had died in Germany and the Low Countries In fact, the epidemic has only lately reached these countries, and, though the total is certainly to be reckoned in hundreds of millions, the deaths so far have been mainly in France The latest news (*Manchester Guardian*, Nov 21) is that the disease is spreading in Western Germany

NTIBIOTIC AND CHEMOTHERAPEUTIC AGENTS IN THE TREATMENT OF NFANTILE DIARRHŒA AND VOMITING

PORT BY A WORKING PARTY * ESTABLISHED BY THE TIBIOTICS CLINICAL TRIALS (NON TUBERCULOUS CONDI ONS) COMMITTEE OF THE MEDICAL RESEARCH COUNCIL

This paper describes the conduct and results of ntrolled therapeutic trials designed to investigate the nical effects of the oral administration of aureomycin, oramphenicol, and sulphadiazine on infantile diar ea and vomiting, excluding salmonella and shigella ections. The work was undertaken at ten separate ntres in Great Britain

mingham	Children's Hospital.
inburgh	Royal Hospital for Sick Children and the City Hospital.
rpool	Alder Hey Children's Hospital.
ndon, G O.S.	The Hospital for Sick Children Great Ormond Street.
ndon, Q E.H	Queen Elizabeth Hospital for Children
ndon, S.A H.	St. Ann's General Hospital.
nchester	Booth Hall Children's Hospital and the Duchess of York Hospital for Babies.
wcastle upon Tyne	General Hospital
effield	Children's Hospital and City General Hospital.
thampton	Children's Hospital and Public Health Laboratory

General Description of Investigation

The investigation began in March, 1950 and continued r about two years. During the first eight months four the centres were engaged on trials of aureomycin and ve on trials of chloramphenicol One of the centres iverpool) using chloramphenicol then began a trial aureomycin also Two months later another centre ondon, S.A.H) not previously participating in the vestigation, began a trial of aureomycin At all the entres the progress of a series of cases treated with he drug under trial was compared with that of a ncurrent series of control cases

The treatment of control cases needs some comment t this stage of the report When the investigation as planned, it was intended that control cases would ceive no antibiotic or chemotherapeutic agent by mouth, at least during the first week of treatment. It later became evident that this intention would be imperfectly realised, since ethical considerations arising from past experience of the treatment of infantile diarrhœa and vomiting influenced the practice at different centres. At most of the centres antibiotic or chemotherapeutic agents were given by mouth to control cases only in occasional circumstances—e g when an infant was not responding to routine methods of treatment and it was considered unjustifiable to withhold additional therapy At one of the centres using aureomycin (London, S.A.H) all the severely ill patients, both aureomycin treated and control, were given sulphadiazine by mouth from the outset. At another centre using aureomycin (London, G O S) a high proportion of controls were given either sulphadiazine or chloramphenicol by mouth.

The implications of these variations in treatment are discussed below, but at this point it is necessary to state that at one centre (Edinburgh) where chloramphenicol was being tried the oral administration of sulphadiazine formed part of the routine method of treatment of control cases From the results obtained at this centre during the first year of the investigation it became evident that sulphadiazine-treated cases would need separate consideration. Accordingly the scope of the investigation was extended and further trials were planned with the object of comparing the therapeutic effects of sulphadiazine with those of chloramphenicol in concurrent series of cases.

All the cases included in the investigation fell therefore, into four main treatment groups aureomycin treated (A) chloramphenicol treated (C) sulphadiazine-treated (S) and controls (R) Table I shows the treatment groups adopted at the various centres and the duration of each trial from the admission of the first to the admission of the last case in the respective series.

Design and Conduct of Trials

TYPES OF CASE INCLUDED

Throughout each of the trials all infants coming under treatment for diarrhœa and vomiting at the centres concerned were included in the investigation, except those who were assessed within twenty four hours of the start of treatment as having no diarrhœa and those who at the start of treatment were aged 1 year or more or fully breast fed or found to have gross structural abnormality or evidence of gross organic disease.

Infants included in the investigation and later found to have either salmonella or shigella infections were excluded from the final analysis of results Infants with parenteral infections were included in the trials and in the final analysis of results, except those who had severe parenteral infections—e g, meningitis, or pneumonia—as their primary disease

INITIAL CLASSIFICATION AND ALLOCATION TO TREATMENT GROUPS

Before allocation to a treatment group each case was classified according to age and to severity of illness The cases were classified according to age at the time of entry to the trial as follows: (1) aged less than 1 month (2) aged 1–5 months and (3) aged 6–11 months

The initial severity of the illness in each case was assessed within twenty four hours of entry to the trial. A case was classified as severe if considered to need parenteral administration of fluid otherwise it was classified as mild.

All the cases included in the investigation were therefore classified within twenty four hours of entry into one of six age and severity groups Throughout each trial successive cases in each age and severity group were allocated in rotation to the appropriate treatment groups as shown in table I except at one centre (London, S.A.H) where a modified random allocation was made (see below) Minor differences in the numbers of cases appearing in concurrent treatment groups were due partly to errors of allocation in the early stages of the investigation and partly to subsequent exclusions because of either salmonella or of shigella infections discovered after entry

ROUTINE TREATMENT

Apart from the oral administration of antibiotic or chemotherapeutic agents each centre continued to use its own routine methods of treatment. These methods differed in detail but the basic principles were similar at all ten centres.

Mild cases were treated with electrolyte solutions with or without the addition of glucose, by mouth for twenty four hours, in quantities adequate to meet a daily fluid requirement of 2½–3 oz per lb of body weight. Dilute

TABLE I—TREATMENT GROUPS AND DURATIONS OF TRIALS AT THE VARIOUS CENTRES

Centre	Trial no	Treatment groups	Duration of trial
Birmingham	1	C R	April, 1950–March, 1951
Birmingham	2	C S	August, 1951–March, 1952
Edinburgh	1	C S	April, 1950–August, 1951
Edinburgh	2	C S	September, 1951–March, 1952
Liverpool	1	C R	March, 1950–October, 1950
Liverpool	2	A C R	November, 1950–May, 1951
Liverpool	3	C S R	June, 1951–March, 1952
London, G O S	1	A R	April, 1950–May, 1951
London, G O S	2	C S	June, 1951–March, 1952
London, Q E H	1	C R	April, 1950–May, 1951
London, Q E H	2	C S R	June, 1951–March, 1952
London, S A H	1	A R	January, 1951–July, 1951
Manchester	1	A R	April, 1950–May, 1951
Newcastle	1	C R	April, 1950–April, 1951
Sheffield	1	A R	April, 1950–May, 1951
Southampton	1	A R	April, 1950–May, 1951
Southampton	2	C S	August, 1951–March, 1952

A, aureomycin.   R, routine (control)
C, chloramphenicol   S, sulphadiazine

milk feeds were then begun and their strength gradually increased until, by the fifth to the eighth day of treatment, depending on the practice at the different centres, feeds were offered sufficient to supply the full daily requirement of 50 calories per lb. body-weight. The type of milk feeds offered and the usual rate of increase in their calorie content varied at different centres.

Severe cases were treated by continuous intravenous infusion of glucose and electrolyte solutions with the addition, at some centres, of dilute human serum or plasma, in quantities adequate from the start of treatment to supply the total daily fluid requirement and to correct dehydration. Oral administration of clear fluid was begun from twelve to twenty-four hours later. Dilute milk feeds were then introduced and their strength gradually increased. Intravenous therapy was continued until oral fluids were well tolerated.

DOSAGES OF TRIAL DRUGS

Dosages of the trial drugs were based on the infant's body-weight on the day of entry to the investigation and were calculated, for each infant in the appropriate treatment groups, according to the following scales:

(A)	aureomycin	75 mg. per lb. a day
(C)	chloramphenicol	75 mg. per lb. a day
(S)	sulphadiazine	125 mg. per lb. a day

The dosages of aureomycin and of chloramphenicol were chosen at the outset of the investigation, when there was little to guide the Working Party except that some of its members had previously given the drugs in these quantities without apparent ill effect. So that the results of treatment might remain comparable, no alteration in dosage was made throughout the investigation.

The drugs were given by mouth in divided doses, at intervals not exceeding six hours, for seven days. Administration was begun as soon as a sufficient time had elapsed to enable the initial assessments to be made, and in no case later than twenty-four hours after entry to the trial. The drugs were dispensed in syrup or some other sweet-flavoured vehicle. Supplies of aureomycin in the form of 250 mg. capsules were found not to be particularly convenient for the measurement of individual doses according to the scale chosen by the Working Party. Otherwise no difficulties were experienced either in dispensing or administering the drugs.

CLINICAL RECORDS

A clinical summary was made of each case included in the investigation to show:

(1) The age and severity classification.

(2) Other criteria chosen for subsequent analysis of the initial comparability of the different treatment groups:
  - (*a*) Source of cases—i.e., from institutional or from domiciliary practice.
  - (*b*) Duration of diarrhœa before entry to the investigation.

(3) The treatment group.

(4) Criteria of clinical progress after entry to the investigation:
  - (*a*) Death or survival.
  - (*b*) Duration of diarrhœa. The interpretation of this criterion—i.e., the time at which the stools became normal in amount and consistence—was left to the individual judgments of the physicians in charge of the cases at each centre.
  - (*c*) Time to clinical recovery. It was agreed by all concerned that clinical recovery implied a satisfactory general condition, stools of normal consistence, and ability to tolerate an adequate diet. At some centres gain in body-weight was included in the assessment of clinical recovery.
  - (*d*) Number of mild cases becoming severe—i.e., subsequently needing intravenous therapy.
  - (*e*) Relapses of diarrhœa. Recurrences of diarrhœ not later than fourteen days after clinical recovery

TABLE II—NUMBER OF CASES IN EACH TRIAL AND DISTRIBUTION OF CASES IN TREATMENT, SEVERITY, AND AGE-GROUPS

Trial	Total no. of cases	Distribution of cases																							
		Treatment group				Severity								Age group											
		A	C	S	R	Mild				Severe				Less than 1 month				1–5 months				6–11 months

were classified as relapses. An arbitrary distinction was made between relapses and recurrences of diarrhœa later than fourteen days after clinical recovery; these were recorded as separate illnesses.

(f) Additional criteria. At three centres (Birmingham, Liverpool and London, Q E.H.) the following additional criteria were used:

(i) Number of severe cases needing prolongation or renewal of intravenous therapy because oral feeding was not tolerated.

(ii) Number of cases making straightforward progress, with toleration of increasing milk feeds, without setbacks necessitating a return to clear fluids or intravenous therapy

(5) Toxic manifestations attributable to the trial drug

BACTERIOLOGICAL INVESTIGATIONS

Rectal swabs and specimens of fæces were examined at each centre for the presence of salmonella and shigella organisms. In addition at five of the centres (Birmingham Edinburgh, Liverpool London, S.A.H and Southampton) examinations were made for *Escherichia coli* O 111 and *B coli O 55* These specific serological types have been found in many countries in recent years in association with infantile diarrhœa and vomiting and some workers have reported their isolation from a larger proportion of severe cases than of mild ones (Holzel et al 1949 Alexander et al 1952) At each of the five centres concerned the *B coli* O 111 and *B coli* O 55 strains isolated from cases at entry to the trial were examined by biochemical and serological methods, the O group being identified by tube agglutination tests.

Clinical Findings

Altogether 1168 cases of infantile diarrhœa and vomiting (789 mild, 379 severe) were included in the analysis of the results of these cases 154 were aureomycin-treated, 415 chloramphenicol treated, 247 sulphadiazine-treated, and 352 controls. The response to treatment of individual cases was assessed solely by their clinical progress

The results in different treatment groups were compared in two stages

(1) The *first stage* was to consider each trial separately The investigation had been so designed as to ensure the allocation of cases of similar age and severity to different treatment groups. The concurrent series in each trial were analysed to verify that the age and severity distributions of the cases were similar and to demonstrate by the other criteria chosen, that the treatment groups were initially comparable. They were further examined to ascertain whether the cases in each group had received similar treatment apart from the administration of the trial drug The treatment groups were next compared as regards the criteria of clinical progress previously listed.

(2) The *second stage* was to bring together the findings obtained at different centres, by collecting the results of all trials in which there were two similar treatment groups. Variations in treatment between different centres were examined The results at centres found to show important variations were analysed separately The results at the remaining centres were combined

The following treatment groups were then compared:

A R, aureomycin treated and concurrent controls.
C R chloramphenicol treated and concurrent controls
C-S chloramphenicol treated and concurrent sulphadiazine treated.

STAGE 1 RESULTS OF SEPARATE TRIALS

Initial Comparability of Treatment Groups

Table II shows the number of cases included in each trial and the distribution of the cases according to their treatment group and to severity of illness and age on entry to the investigation.

Table III shows, for each of the concurrent series the sources of the cases and the average duration of diarrhœa before entry to the investigation. In both these characteristics the different treatment groups as shown in the following summary of table III were similar enough to justify comparisons between them of subsequent clinical progress

Treatment groups	*Percentage of cases from domiciliary practice*		*Average duration of diarrhœa before entry to trial*
A R	A 71 %	R 68 %	A 4·9 days, R 4·6 days
C-R	C 71 %	R 68 %	C 3·8 days, R 4·0 days
C-S	C 68 %	S 70 %	C 4·3 days, S 4·2 days

Variations in Treatment

Details of routine treatment varied at different centres, but each centre aimed to apply its usual methods to all cases irrespective of the treatment group to which they were allocated Possible bias in this respect was obviated at two centres (Edinburgh 2nd trial and London S.A.H.) where trials were conducted blind —i.e., without the physicians knowing which patients were receiving the trial drug

All patients in the treatment groups A C and S were given the respective drug according to the agreed dosage. Patients in the control group (R) were normally given no antibiotic or chemotherapeutic agent by mouth during the first week of treatment At one centre (London S.A H) sulphadiazine was given by mouth in all severe cases, irrespective of the treatment group At another centre (London, Q.E H) penicillin was given intramuscularly in all severe cases as a routine prophylactic measure during intravenous therapy

Infants found to have, either at the time of their entry to the investigation or during the subsequent course of their illness, a parenteral infection considered to need

TABLE IV—CLINICAL PROGRESS OF CASES IN EACH OF THE TRIALS

specific treatment were usually given penicillin intramuscularly Sulphonamides or antibiotics other than the drug appropriate to the treatment group were given by mouth to some patients whose progress was considered to be unsatisfactory and to some patients for the treatment of parenteral infections Details of such additional chemotherapy are recorded in the second stage of the analysis of the results

Clinical Progress

Table IV gives the results obtained in each of the trials It shows the number of cases included in the investigation at each centre and their clinical progress as regards the criteria chosen. Durations of diarrhœa and times to clinical recovery have been expressed as averages for each treatment group The relation of clinical progress to treatment group is seen to follow a general trend from more rapid recovery in the sulphadiazine treated and chloramphenicol-treated groups to less rapid recovery in the aureomycin-treated and control groups The statistical significance of the observed differences is dealt with in the second stage of the analysis

STAGE 2 COMPARISON OF TREATMENT GROUPS

Aureomycin treated and Concurrent Control Groups

The numbers for comparison from the six centres concerned (Liverpool 2, London, G O S 1, London, S A H , Manchester, Sheffield, and Southampton 1), were 154 cases in the aureomycin treated group and 161 cases in the control group

The method of the trial at London, S.A H differed from that at the other centres in several important respects the trial was, throughout, conducted " blind ", cases within each age and severity group were allocated at random to treatment groups, all the control patients were given by mouth an inert yellow powder indistinguishable in appearance from aureomycin, and all severe cases were treated with sulphadiazine by mouth, irrespective of treatment group The results obtained at this centre have therefore been analysed separately

Important variations also were recorded at London, G O S , where sulphonamide derivatives were given by mouth to 7 of the 42 patients in the aureomycin-treated group and to 27 of the 50 controls Additional antibiotic therapy given to controls comprised the following, either chloramphenicol or aureomycin by mouth to 13 infants whose clinical condition was not improving under routine treatment, penicillin parenterally in 14 cases, and streptomycin parenterally in 8 cases The variations recorded were sufficiently large to necessitate separate analysis of the results obtained at this centre

At the other centres using aureomycin additional chemotherapy was given in only a small proportion of cases, mainly in the control group

Table V shows a comparison of the aureomycin treated and concurrent control groups At London, G O S the proportion of mild cases becoming severe was significantly higher in the control group (χ^2 = 11 24 n = 1 P<0 001) This difference, which was supported by the results at London, S A H , was the only statistically significant difference between the two treatment groups No statistically significant difference was demonstrated, at any of the centres, in the average duration of diarrhœa after entry to the trial or in the average time to clinical recovery The number of cases relapsing after clinical recovery was slightly higher in the aureomycin treated group

Chloramphenicol-treated and Concurrent Control Groups

The numbers for comparison from the four centres concerned (Birmingham 1, Liverpool 1, 2, and 3, London, Q E H , 1 and 2, and Newcastle) were 210 cases in the chloramphenicol-treated group and 210 cases in the control group The principles of routine treatment were similar at all four centres At Birmingham 4

TABLE V—COMPARISON OF AUREOMYCIN TREATED (A) GROUPS AND CONCURRENT CONTROL (R) GROUPS

—	Centre	Mild cases		Severe cases		Total	
		A	R	A	R	A	R
Total no of cases	London, G O S	29	32	13	18	42	50

	London S.A H.	4 6	5 0	6 2	7 4	4 9	[illegible]
	Other centres	6 9	7 1	7 1	7 3	7·0	[illegible]
Average time to clinical recovery (days)	London, G O.S	16 9	20 3	19 3	20·5	17·6	[illegible]
	London S A.H	14 5	13 3	11 9	11 1	13 5	[illegible]
	Other centres	11 3	12 7	14 1	14 4	12 5	[illegible]
No of mild cases which became severe	London, G O S	1	14				
	London S A.H	1	5				
	Other centres	4	6				
No of cases which relapsed	London G O S	2	1	1		3	1
	London, S A.H	4	6	3	1	7	1
	Other centres	2			1	2	1

patients all in the control group, were given sulphonamides by mouth because of unsatisfactory progress At Liverpool 3 patients in the chloramphenicol treated group were later given either penicillin or streptomycin intramuscularly for the treatment of parenteral infections, in the control group some patients were given penicillin intramuscularly and 2 patients whose condition was deteriorating were given chloramphenicol by mouth after the end of the first week of treatment At London Q E H., penicillin was given intramuscularly to patients in both groups for the treatment of parenteral infections, in the control group 8 patients, whose conditions were deteriorating, were given chloramphenicol by mouth after intervals ranging from six to fourteen days from the start of treatment. At Newcastle 2 patients in the chloramphenicol treated group were given penicillin intramuscularly for parenteral infections and in the control group most of the patients were given penicillin intramuscularly, 6 were given sulphadimidine by mouth, 4 were given streptomycin, and 2 aureomycin and 2 whose condition was deteriorating were given chloramphenicol by mouth after the end of the first week of treatment. The recorded variations in treatment were proportionately greater at Newcastle than at the other centres using chloramphenicol but the numbers involved were comparatively small. The results at all four centres have therefore been combined in the second stage of the analysis.

TABLE VI—COMPARISON OF CHLORAMPHENICOL TREATED (C) GROUPS AND CONCURRENT CONTROL (R) GROUPS

—	Mild cases		Severe cases		All cases	
	C	R	C	R	C	R
Total no. of cases	138	138	72	72	210	210
No. of deaths	1	2	3	4	4	6
No. of survivors	137	136	69	68	206	204
Average duration of diarrhœa after entry (days)	5·6	8·3	6·7	10·0	6·0	8·9
Average time to clinical recovery (days)	9·6	13·1	11·5	15·6	10·3	14·0
No. of mild cases which became severe	4	23				
No. of cases which relapsed	4	5	6	2	10	7

Total no. of cases	118	120	67	66	Additional criteria used at three of the centres
No. of severe cases which needed prolonged intravenous therapy			3	28	
No. of cases which made straightforward progress	110	79	64	37	

Table VI shows a comparison of the chloramphenicol treated and concurrent control groups The average duration of illness after entry to the trial was less in the chloramphenicol treated group than in the control group. Statistically significant differences in favour of the chloramphenicol treated group were demonstrated as regards the average duration of diarrhœa ($t = 4·98$, $n = 408$, $P < 0·001$) the average time to clinical recovery ($t = 4·66$ $n = 408$, $P < 0·001$) and the numbers of mild cases becoming severe ($\chi^2 = 20·36$, $n = 1$, $P < 0·001$) The relative improvement in progress in the chloramphenicol-treated group was of the same order in both mild and severe cases. The number of cases relapsing after clinical recovery was small but was higher in the chloramphenicol treated group

Chloramphenicol treated and Concurrent Sulphadiazine treated Groups

The numbers for comparison from the six centres concerned (Birmingham 2, Edinburgh 1 and 2, Liverpool 3, London, G O.S. 2, London, Q E H, 2, and Southampton 2) were 243 cases in the chloramphenicol treated group and 247 cases in the sulphadiazine treated group The principles of routine treatment were similar at all six centres Penicillin was given intramuscularly for the treatment of parenteral infections to some patients in each of the treatment groups. Apart from this additional antibiotic or chemotherapeutic treatment was rarely given. The variations recorded were not so numerous as to invalidate comparison of the two treatment groups At two of the centres (Liverpool 3 and London, Q E H., 2) concurrent series of control cases allowed a comparison of three treatment groups (C S, and R)

TABLE VII—COMPARISON OF CHLORAMPHENICOL TREATED (C) GROUPS AND CONCURRENT SULPHADIAZINE-TREATED (S) GROUPS

—	Mild cases		Severe cases		All cases	
	C	S	C	S	C	S
Total no of cases	171	182	72	65	243	247
No. of deaths	2	0	1	4	6	4

Average duration of diarrhœa (days)	7·1	5·7	7·8	6·3	7·3	5·8
Average time to clinical recovery (days)	13·5	12·0	16·5	14·5	14·1	12·6
Number of mild cases which became severe	10	11				
Number of cases which relapsed	7	13	7	2	14	15

Table VII shows a comparison of the chloramphenicol treated and concurrent sulphadiazine-treated groups. The average duration of illness after entry to the trial was less in the sulphadiazine-treated group than in the chloramphenicol treated group Statistically significant differences in favour of the sulphadiazine treated group were demonstrated as regards the average duration of diarrhœa ($t = 2·30$, $n = 478$ $0·01 < P < 0·02$) and the average time to clinical recovery ($t = 2·50$ $n = 478$, $0·01 < P < 0·02$) The relative improvement in progress in the sulphadiazine-treated group was of the same order in both mild and severe cases. There was no significant difference between the two treatment groups in the proportion of mild cases becoming severe.

A direct comparison of sulphadiazine-treated and control groups was made at two centres only (Liverpool 3 and London, Q.E H, 2) In concurrent series at these centres 38 cases were allocated to the chloramphenicol treated group 35 cases to the sulphadiazine treated group, and 38 cases to the control group Significant differences were demonstrated between the sulphadiazine-treated and control groups as regards the average duration of diarrhœa after entry to the investigation ($t = 2·40$ $n = 70$ $0·01 < P < 0·02$) and the average time to clinical recovery ($t = 2·77$ $n = 70$ $P < 0·01$) The differences between the chloramphenicol treated and control groups were statistically not quite significant it is reasonable

TABLE VIII—DISTRIBUTION ON ENTRY TO THE TRIALS OF *E coli* O 111 AND *E coli* O 55 POSITIVE AND NEGATIVE CASES RESULTS FROM THE FIVE CENTRES CONCERNED

Trial	No. of cases *E. coli* O 111 positive				No. of cases *E coli* O 55 positive				No of cases *E. coli* O 111/O 55 negative				Total no. of cases			
	A	C	S	R	A	C	S	R	A	C	S	R	A	C	S	R
Birmingham 1		11		6		21		15		5		15		37		36
Birmingham 2			3							12	11			12	14	
Edinburgh 1		20	19			17	17			64	69			101	105	
Edinburgh 2		4	5			9	8			16	14			29	27	
Liverpool 1		14		15		7		5		19		20		40		40
Liverpool 2	11	10		11					7	8		8	18	18		19
Liverpool 3		11	10	8						14	12	12		25	22	20
London, S.A H	5			4	2			2	21			22	28			28
Southampton 1	1			2				1	26			29	27			32
Southampton 2		1				4	3			17	19			22	22	

to assume that this was due to the small numbers of cases, because the actual differences observed were of the same order as those observed in other C-R series

NUMBER OF DEATHS

The total number of deaths was 33, giving an over all fatality rate of 2 8% The numbers of deaths in each treatment group, with the corresponding fatality-rates, were aureomycin-treated 6 (3 9%), chloramphenicol treated 9 (2 2%), sulphadiazine-treated 4 (1 6%), controls 14 (4 0%)

TOXIC MANIFESTATIONS ATTRIBUTABLE TO TRIAL DRUGS

In a small proportion of cases skin eruptions were observed that were attributable to possible toxic effects of the drug under trial In the chloramphenicol-treated group 14 infants developed rashes, 6 of these were eczematous in appearance and associated with blood eosinophilia, 2 cases of exfoliative dermatitis were recorded In the aureomycin-treated group 3 infants developed erythema of the hands and feet, and 2 others developed induration of the hands In the sulphadiazine treated group skin rashes were reported in 3 cases

Bacteriological Findings

Infants admitted to the investigation and found to have either salmonella or shigella infection were excluded from the analysis of the clinical results Of the remaining 1168 cases 745 were treated at the five centres where examinations were made for *E coli* O 111 and *E coli* O 55

Table VIII shows the results obtained from examination of rectal swabs, or of specimens of fæces, taken from these infants at the time of their entry to the investigation or, in some cases, on the day after their entry. The results refer to 727 patients from whom specimens were collected before treatment was begun with aureomycin, chloramphenicol, or sulphadiazine 18 cases were excluded because relevant specimens were either not obtained or not examined

It is seen from table VIII that at four of the five centres, among a total of 628 cases, these specific *E coli* types were found to be almost equally distributed between the respective treatment groups of cases in each trial This finding afforded additional evidence, independent of the clinical observations, of the initial comparability of the treatment groups at these four centres The observed differences between the groups, as regards clinical response to treatment, could not therefore be attributed to the preponderance, in any one group, of cases from which these *E coli* types were isolated at the time of entry to the trial At the fifth centre (Birmingham), for no known reason, *E coli* O 111 and *E coli* O 55 were isolated from chloramphenicol-treated patients in higher proportion than from the concurrent controls

Separate reports are in preparation at two centres (Edinburgh and Liverpool) regarding the relation of the bacteriological findings to the clinical progress of their cases

Discussion

It has long been recognised that non specific infantile diarrhœa and vomiting is, in many instances, a manifestation of some acute infection Because the identity of the infective agent, or agents, concerned has not yet been established, treatment of the disease with chemotherapeutic or antibiotic drugs has lacked an experimental basis Nevertheless in the past ten to fifteen years most of the sulphonamides and the newer antibiotics have been tried empirically, and their effects on the course of the illness judged by clinical observations During the same period the prognosis of infantile [illegible] and vomiting has greatly improved, a change contemporaneous with the adoption of more effective measures for the treatment of dehydration Results attributed to particular drugs need therefore to be considered in relation to improvements in current methods of routine treatment

Many of the published results are difficult to assess Some workers have treated cases with chemotherapeutic or antibiotic agents and have reported their results without reference to concurrent control cases treated by routine methods Others have described controlled investigations of cases in numbers too small to have established statistically significant differences between the treatment groups Well controlled trials with adequate numbers of cases have been relatively uncommon In Great Britain the therapeutic use of streptomycin has been tested critically by several groups of workers (Holzel et al 1949, Lowdon and McNeill 1951, Young et al 1951, Alexander et al 1952), who failed to substantiate the claims made for this drug by previous investigators

Various sulphonamides have been used for the treatment of infantile diarrhœa and vomiting Favourable results have been reported with sulphathiazole (Taylor 1941), succinylsulphathiazole (Twyman and Horton 1943), sulphaguanidine (Henderson 1943), and sulphadiazine (Kirsch and Nieckau 1943, Tudor 1943), A controlled investigation of sulphadiazine was made by Klose (1947), who found that the drug did not appear to have any effect on the course of the disease Some workers have continued to use sulphonamides for the treatment of associated parenteral infections, and a few have considered that these drugs may exert a favourable influence even in the absence of signs of parenteral infection, though opinions on this matter have been divided (see Hinden 1948)

Good results have also been reported with the use of chloramphenicol (Rogers et al 1949, Clément et al 1950, Smellie 1950, Piette and Vézina 1951) and of aureomycin (Magnusson et al 1950, Laurell et al. 1951, Sacrez et al 1951, Chedid et al 1951) In a controlled investigation of both of these antibiotics Shanks (1951) found no significant difference between either of the two treated series and the controls, but it is noteworthy that the controls were given penicillin and/or sulphonamides as indicated, on the assumption that neither of the two latter drugs could be regarded as in any way specifically effective in the treatment of infantile diarrhœa

The results of the present trials showed that the groups of patients treated with either sulphadiazine or chloramphenicol progressed more favourably than the group given routine treatment only, and that benefit to a more limited extent might also be attributed in some cases to treatment with aureomycin Analysis of the findings was complicated by the introduction of sulphadiazine into trials designed originally to investigate the effects of either aureomycin or chloramphenicol. Some of the early results suggested that sulphadiazine was at least as effective in treatment as chloramphenicol This necessitated the separate consideration of those trials in which sulphadiazine was extensively used in the treatment of the control cases As evidence of the value of sulphadiazine accumulated, further trials were deliberately designed to compare the effects of sulphadiazine with those of chloramphenicol

In the trials of aureomycin no statistically significant difference was demonstrated between the aureomycin-treated and control groups in their average durations of diarrhœa or average times to clinical recovery At two of the centres concerned (London, G O S, and London, S A H) the interpretation of this finding was rendered uncertain by reason of the use at these centres of sulphadiazine in the treatment of control cases At the same two centres it was found that the number of mild cases becoming severe was significantly less in the aureomycin treated group, a result unlikely to have been influenced by the use of sulphonamides, since chemotherapeutic agents were seldom given in mild cases in the control group unless the clinical condition had already begun to deteriorate. At the other centres using aureomycin no significant difference between the aureomycin treated and control groups was shown as regards any of the chosen criteria of clinical progress in spite of the fact that only a few of the controls were treated with sulphonamides. The evidence obtained therefore suggests that aureomycin prevented deterioration in some of the mild cases at two of the centres but no other beneficial effect of the drug was detected.

In contrast, the results obtained in the trials of chloramphenicol showed that this drug was effective in shortening the duration of diarrhœa and in hastening clinical recovery It was also found to be effective in preventing mild cases from becoming severe and in promoting straightforward progress in both mild and severe cases Similar routine treatment was given to all the cases, both chloramphenicol treated and controls and relatively few of the controls were treated with any chemotherapeutic or antibiotic agent by mouth Occasionally controls were given chloramphenicol when at the end of at least five days routine treatment their clinical condition was causing anxiety The numbers involved were small, and the significance of the differences between the two treatment groups was not obscured by this additional therapy

The trials designed to compare the effects of chloramphenicol with those of sulphadiazine arose as a result of the findings at one centre (Edinburgh) where sulphadiazine was given by mouth as part of the routine treatment. Preliminary results at this centre suggested that sulphadiazine might prove to be at least as effective as chloramphenicol. Subsequent trials supported this conclusion In the final analysis significant differences in favour of the sulphadiazine-treated group were found as regards the average duration of diarrhœa and time to clinical recovery There was no significant difference between the two groups in the proportion of mild cases becoming severe At two centres (Liverpool and London, Q E H) where the progress of concurrent control groups was also studied, the results confirmed the efficacy of sulphadiazine compared with routine, treatment.

In assessing the results of the investigation as a whole it should be emphasised that all the trials were made against a background of highly effective supportive treatment. The fatality rate was 2 8% of the total cases and, even in the control group was not higher than 4% The number of deaths in the control group may have been influenced by the use of chemotherapeutic or antibiotic agents which were given to some infants, whose clinical condition was deteriorating, to improve their chances of recovery For this reason the fatality rate was considered an unreliable criterion for the comparison of trial and control groups. The differences between the fatality rates in the various treatment groups, though not large enough to be statistically significant, were consistent, however with the differences observed as regards the other criteria of clinical progress.

More than half the controls made straightforward progress to recovery without chemotherapeutic or antibiotic treatment. Nevertheless the proportion of mild cases becoming severe was significantly greater in the control group (14%) than in the aureomycin treated (4%) chloramphenicol treated (3%) or sulphadiazine-treated (4%) groups. This finding suggests an important use for these drugs in the prevention of clinical deterioration of mild cases not responding initially to routine methods of treatment. Moreover the administration of sulphadiazine or of chloramphenicol but not of aureomycin, was shown to reduce the average duration of illness in both mild and severe cases.

Selection of the most appropriate drug for the treatment of individual cases of infantile diarrhœa and vomiting may become possible when more is known of the ætiology of the disease. The results of the present investigation indicate sulphadiazine and chloramphenicol as the drugs of choice, with the balance of evidence in favour of sulphadiazine, and their oral administration may be considered as a valuable addition to established methods of treatment It should be realised, however, that adequate supportive therapy still remains of paramount importance and that treatment with either of these drugs is not devoid of the risk of toxic manifestations attributable to their use.

Summary

Controlled trials of aureomycin, chloramphenicol, and sulphadiazine in the treatment of infantile diarrhœa and vomiting were made at ten separate centres in Great Britain during 1950–52.

The trial drugs were administered by mouth in doses of respectively 75 mg, 75 mg., and 125 mg per lb body weight a day for seven days

A total of 1168 cases (789 mild, 379 severe) was included in the analysis of the results. Infants found to have either salmonella or shigella infections were excluded from this analysis.

The numbers in the different treatment groups were 154 aureomycin treated 415 chloramphenicol treated 247 sulphadiazine treated and 352 controls The mean fatality rate was 2 8%

Clinical progress after the start of treatment was assessed on the following criteria average duration of diarrhœa average time to full clinical recovery and proportion of mild cases which became severe.

The aureomycin treated group progressed more favourably than the controls as regards the proportion of mild cases which became severe but not as regards the two other criteria

The chloramphenicol treated and sulphadiazine-treated groups progressed more favourably than the controls as regards all three criteria. The progress of the sulphadiazine-treated group was significantly better than that of any other treatment group

The use of aureomycin, chloramphenicol, or sulphadiazine as a therapeutic measure additional to established routine methods of treatment is discussed.

The Working Party desires to express its thanks for facilities afforded by hospital and other authorities at the centres concerned; and for the assistance of those members of the medical nursing and technical staffs who coöperated in this investigation.

GASTRIC ASPIRATION IN HÆMATEMESIS

G N Chandler

SENIOR REGISTRAR

G Watkinson
M D Lond., M R C P
LECTURER IN MEDICINE

From the University Departments of Clinical Medicine and Medicine, The General Infirmary at Leeds

The early recognition of recurrent hæmorrhage and the accurate identification of the site of bleeding in hæmatemesis and melæna are of great clinical importance but are also beset with difficulties Kinsella (1950) reported favourably on the use of an indwelling tube for the recognition of recurrent hæmorrhage There is a real need for a safe bedside method that would yield reliable diagnostic and prognostic information

It was thought that in the acute stages of gastroduodenal hæmorrhage some abnormality of gastric secretion of diagnostic value might be present For this reason 24 hour gastric analysis (James and Pickering 1949) previously used in the study of peptic ulcer and achlorhydria (Watkinson 1951, Watkinson and James 1951) has been applied to the problem We report here the results of twenty four-hour gastric analysis in 105 consecutive and unselected patients admitted, as emergencies, with hæmatemesis or melæna to the medical wards of the General Infirmary at Leeds and St James's Hospital, Leeds, in the last year

TABLE I—CLINICAL MATERIAL STUDIED

Diagnosis	No of cases	Diagnostic criteria				
		Operation	Radiography		Gastroscopy	Necropsy
			Positive	Negative		
Chronic G U	17	6	9		5	
Chronic D U	35	6	32			1
Acute ulcer	42	5	2	31	13	2
Postoperative bleeding	7	4	2		5	
Hiatus hernia	4		4			

In many patients the investigations were duplicated.

Procedure

The modern régime for the treatment of hæmatemesis was followed, with early and liberal feeding as recommended by Meulengracht (1935) and modified in this country by Witts (1937), together with the generous use of blood by drip transfusion A Ryle's tube was passed shortly after admission and, where feasible, the position of the tip of the tube was assessed radiologically and adjusted to the angulus X ray control was impracticable in the acutely ill patients and this is a potential source of error in this study 5–10 ml of stomach contents was aspirated hourly by day and by night, and the pH of these unfiltered samples was estimated with a sealed glass electrode The presence of recent or old blood-staining in the aspirated specimens was recorded on a chart devised for the purpose, on which measurements of pulse rate and blood pressure were also plotted, together with the amounts of transfused blood and episodes of further hæmorrhage In this way a continuous and sequential record of progress was readily available at the bedside, and proved of great value in the hour-to-hour management of each patient No evidence was obtained to suggest that the presence of an indwelling tube stimulated recurrence of bleeding or favoured its continuance or that the mortality rate was adversely affected The dangers of this procedure appear to be largely theoretical, and in our opinion anxiety on this score is unwarranted The tube was left in situ for periods averaging between forty-eight and seventy two hours, aspirations being continued for at least twelve hours after bleeding had ceased The patients tolerated the procedure well, the small interference necessary to obtain the gastric samples neither disturbing sleep nor impairing appetite

Confinement of the patient to bed at strict rest was enforced for at least three weeks when barium examination of the stomach and duodenum was undertaken. Some patients were gastroscoped in the first week when it was thought that this would prove helpful to diagnosis. In the remainder verification was obtained either at operation or at necropsy

Clinical Material

Many workers have emphasised the difficulty of identifying the site of bleeding in hæmatemesis, since in the acute stages there is no certain method of diagnosis save operation, and the final conclusion must be reached in retrospect Even at necropsy it may be impossible to decide the source of bleeding, particularly if multiple lesions exist Only by the careful integration of early gastroscopy and comprehensive radiological control can results comparable to those achieved by Avery Jones (1952) be obtained, and we have adopted a method of classification similar to that used by him

Chronic Gastric Ulcer

Of the 17 patients in this group the ulcer was shown at operation in 6, by radiological examination in 9, and at gastroscopy in 4, the investigations being duplicated in 3 patients All the ulcers were reckoned benign Associated lesions included 1 patient with hiatus hernia, 1 with pyloric stenosis, and 1 with duodenal ulcer

Chronic Duodenal Ulcer

Of the 35 patients so classified the ulcer was demonstrated at operation in 6, radiologically in 32, and at necropsy in 1 Associated lesions were pyloric stenosis in 1 patient, hiatus hernia in 2, and carcinomatosis and cardiac infarction in the fatal case

Acute Ulcer

The following criteria have determined this classification in 42 patients

Gastroscopic confirmation —Definite evidence of acute ulcer was obtained in 13 patients by gastroscopy done within a week of admission

Operative and necropsy verification —Acute ulceration was confirmed at operation in 5 patients and at necropsy in 1

Positive radiological evidence —The presence of an ulcer crater without deformity of the duodenal cap enabled a confident radiological diagnosis of acute duodenal ulcer to be made in 2 patients

Negative radiological findings —In 31 patients a negative barium meal examination, done three weeks after hæmorrhage had ceased, allowed the presumptive diagnosis of acute peptic ulcer

TABLE II—AGE AND SEX DISTRIBUTION OF PATIENTS STUDIED

Diagnosis	Sex	Age (yr)							Tot
		0–20	21–30	31–40	41–50	51–60	61–70	70+	
Chronic G U	M			3	5	1	2	1	13
	F				2	1		2	5
Chronic D U	M	1	1	6	8	10	5	1	31
	F			1	1		1	1	4
Acute ulcer	M	1	4	8	3	6	1	2	25
	F	1	1	2	3	5	4	1	17
Postoperative bleeding	M				3	4			7
	F								
Hiatus hernia	M				1		1	1	3
	F						1		1
Total		3	6	10	20	27	15	9	10

Postoperative Group

Of the 7 patients in this group gastro-enterostomy had been performed for chronic duodenal ulcer in 4 and for gastric carcinoma in 1 3 patients had previously been ubmitted to gastrectomy for duodenal ulceration Operation showed chronic duodenal ulcer as the site of bleeding in 2 patients and anastomotic ulcer in 2.

Œsophageal Hiatus Hernia

4 patients were shown to have hiatus hernia and reflux œsophagitis, hæmorrhage presumably originating in that site

The *diagnostic criteria* are summarised in table I

The *age and sex distribution* of the patients studied are summarised in table II and are similar to those of the largest reported series. The usual male preponderance was found in the chronic ulcer group acute peptic ulcer being relatively more common in women (Avery Jones 1952)

The *length of a history* of preceding dyspepsia supported the eventual diagnosis (fig 1); 36 of the 52 patients with chronic ulcers had had dyspepsia for more than five years, and 13 between one and three years Of the 42 patients in the acute ulcer group 18 gave histories of less than a week, 4 between one or two weeks and 8 between two and four weeks.

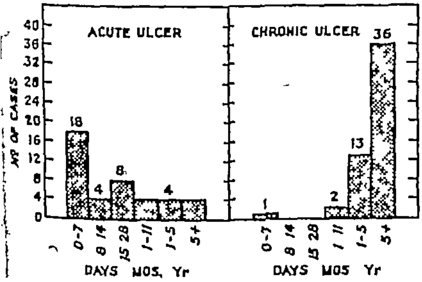

Fig. 1—Relation of length of history to type of ulcer finally diagnosed. Of 52 patients with chronic ulcer 36 patients had histories of dyspepsia exceeding 5 years and 13 of 1–5 years; whereas of 42 patients with acute ulcer 18 had histories of less than a week, 4 of 1–2 weeks, and 8 of 2–4 weeks.

Value of Gastric Aspiration in Management of Patient

SIGNIFICANCE OF BLOODSTAINING

The bedside observation of bloodstaining in the aspirated specimens was found of great value in the treatment of individual patients, because warning of further hæmorrhage might thus be obtained before other clinical criteria indicated it occasionally information about the site of the ulcer was provided. The finding of fresh blood in the hourly specimens is to be expected in the early stages after gastroduodenal hæmorrhage, and the usual course of events (fig 2) is for this staining to diminish in intensity and to appear older until the samples are finally returned clear Bloodstaining was usual in patients with chronic gastric ulcer (14 of 17 cases) was less frequently observed in acute ulcer (23 of 42) and was least common in chronic duodenal ulcer (16 of 35)

Evidence about the site of the ulcer was obtained in 7 patients admitted with hæmatemesis. In these patients, though bleeding continued with the passage of frequent melæna stools, the gastric samples became rapidly clear indicating that the site of hæmorrhage lay distal to the stomach. All these patients, as anticipated, had duodenal lesions, and 3 required surgery for their eventual control. Fig 3 illustrates the findings in 1 patient whose continued melæna necessitated the transfusion of 10 pints of blood in the first two days; the gastric aspirations showed old blood by the third hour and later cleared completely The association of clear specimens with evidence of continued bleeding usually indicates that the source of bleeding is beyond the pylorus

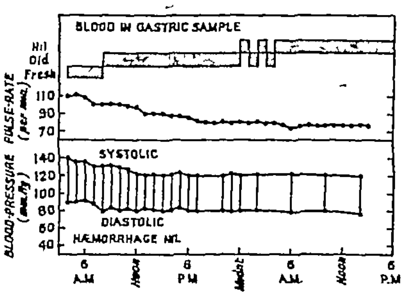

Fig. 2—Results of hourly gastric aspiration in a patient with a gastric ulcer After initial fresh bloodstaining samples contain old blood and become finally clear indicating cessation of bleeding.

The imminence of recurrent hæmorrhage has been anticipated, often by many hours, by the reappearance of fresh blood in the aspirated specimens, before other criteria have indicated relapse. The patient whose chart is shown in fig 4 was bleeding from a chronic gastric ulcer After twice vomiting blood on the first day he appeared to improve with the transfusion of 3 pints of blood Although there was no further evidence of hæmorrhage in the next three days, blood was consistently present in the aspirated specimens, antedating by many hours the hæmatemesis on the fifth day Early recognition of recurrent hæmorrhage was similarly forthcoming in 26 patients, proving most useful in those with acute and chronic gastric ulcers and of least value in patients with duodenal lesions.

SIGNIFICANCE OF INTRAGASTRIC pH

The method of twenty four hour gastric analysis aims at studying changes in gastric acidity on a normal diet and has yielded interesting results in the study of peptic ulcer and achlorhydria (James and Pickering 1949 Watkinson 1951 Watkinson and James 1951) Though

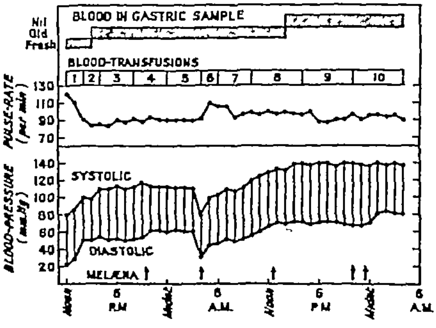

Fig. 3—A patient with a bleeding duodenal ulcer studied by hourly gastric aspiration. Although bleeding was obviously continuing (judged by pulse-rate, melæna, and necessity for continued transfusion) gastric samples became rapidly clear indicating that source of hæmorrhage was distal to stomach.

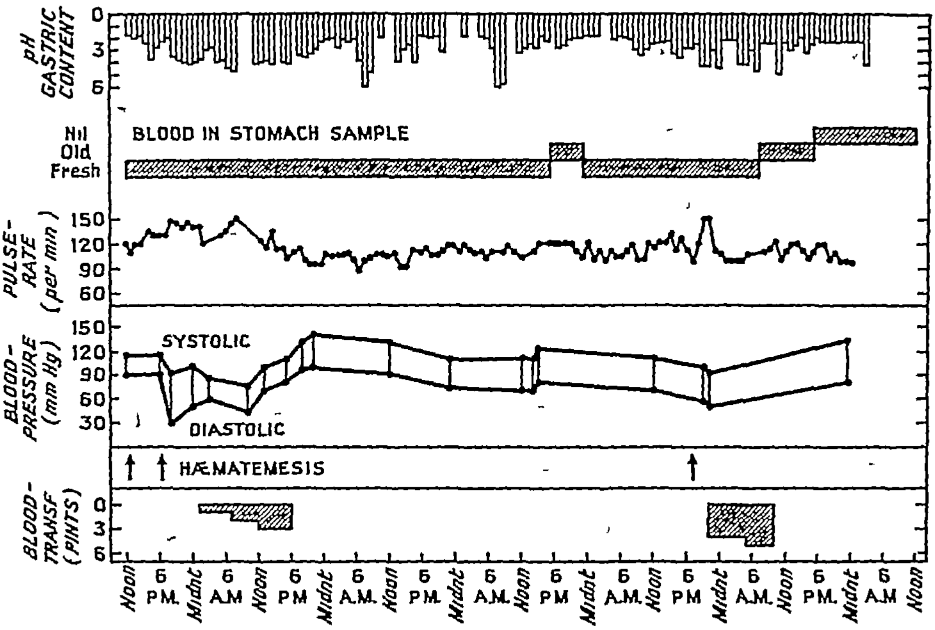

Fig 4—Hourly gastric aspiration in a patient bleeding from a chronic gastric ulcer, after 2 hæmatemeses on the first day clinical criteria suggested that bleeding had ceased, but copious amounts of fresh blood were aspirated in the next 3 days and antedated by many hours the third hæmatemesis on the fifth day

normal people show considerable variability in nocturnal pH, acid values are rarely more alkaline than pH 4 5 In patients with duodenal ulceration a high night acidity is usual, whereas about half the patients with gastric ulcer show steep nocturnal falls in acidity approximating to alkaline levels

In this investigation the changes in gastric acidity were estimated immediately after gastroduodenal hæmorrhage in an attempt to obtain diagnostic information. Three types of abnormal secretion pattern were recognised

(1) *Nocturnal neutralisation*—In patients of this type nocturnal reductions in acidity approximating to alkaline levels were observed and pH values exceeding 5 5 were obtained 2 examples are shown in fig 5

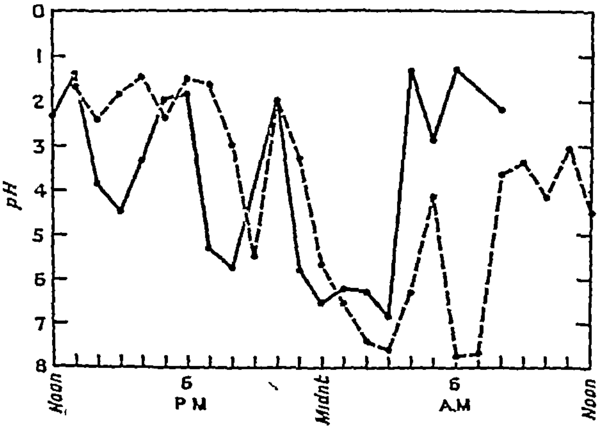
(2) *High nocturnal acidity*—In these patients the night acidity is abnormally high, lying between pH 1 and pH 2 Fig 6 illustrates 2 typical examples

(3) *Achlorhydria*—The third type of abnormal pattern depends on the recognition of achlorhydria, where the pH of specimens is more alkaline than that of Töpfer's reagent (pH 3 5) in most of the samples throughout the twenty four hours, 2 such examples are shown in fig 7 The finding of acid in the last few specimens is not uncommon and succeeded an initial achlorhydria in 9 patients.

These varieties of secretion pattern, obtained in the acute stages of the illness, had a significant relation to the site and type of ulcer, and were sufficiently clear to be of diagnostic value In 13 patients, however, the acid values obtained were not abnormal, the achlorhydria, observed consistently in the postoperative group, reflected the disturbance in gastric function following operation and was of no diagnostic use. The frequency distribution of secretion patterns between gastric, duodenal, and acute ulcers and hiatal lesions is shown in fig 8. Of 31 patients showing high night acidity, 27 proved later to have chronic duodenal lesions, 14 of 18 patients showing nocturnal neutralisation had chronic gastric ulcers, and, perhaps most significant of all, the finding of achlorhydria distinguished the acute ulcers, because 32 of 36 patients showing this phenomenon were finally recognised as having bled from an acute ulcer Of 4 patients with hiatal lesions 1 had high nocturnal acidity, 2 had achlorhydria, and 1 had normal night acidity

The finding of normal night acidity in 13 patients was of no diagnostic importance, being evenly distributed among the various types of ulcer, and the achlorhydria invariably found in the 7 patients of the postoperative group was clearly of no significance The reliability of the secretion patterns in the remaining 85 patients is indicated in table III, a correct diagnosis being achieved in 73 (85 9%) Reliable diagnostic information was obtained in 14 of 18 patients showing nocturnal neutralisation (77 8%), in 27 of 31 showing high night acidity (87 1%), and in 32 of 36 patients with achlorhydria (88 9%), statistical tests show these findings to be significant in all groups

The difference between the groups can also clearly be seen by calculating the mean pH values observed at



5—In 2 patients bleeding from chronic gastric ulcer reductions in nocturnal acidity approximating to alkaline levels.

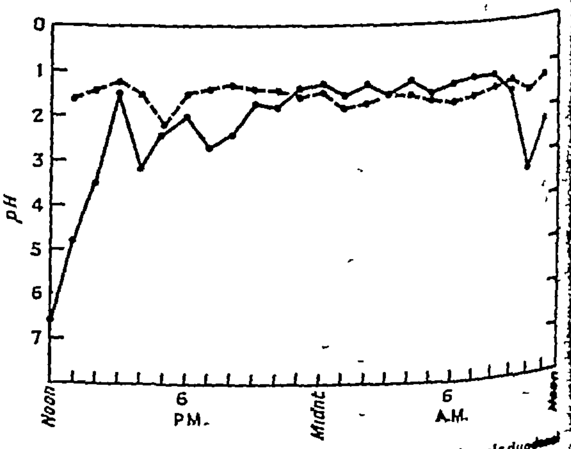


Fig 6—High night acidity in two patients bleeding from chronic duod ulcers.

each hour in the patients studied. Hunt (1952) has described averages of pH values as "means of the negative logarithm of hydrogen ion concentration which have no physiological or clinical meaning" Whatever may be the mathematical limitations of these values they serve as efficient units of comparison between the groups of patients studied. In fig 9 the hourly mean pH values have been calculated, together with the standard error of the observations. Highest values were present in the patients with chronic duodenal ulcer and ranged between pH 2 33 (± 219) and pH 3 29 (± 421), with high nocturnal acidity, at no time was a pH of 3 5 exceeded In the patients with chronic gastric ulcer alkaline values ranging between pH 3 94 (± 482) and pH 5 14 (± 517) were observed at night, coinciding with nocturnal neutralisation in most of these patients. In patients with acute ulcers mean pH values were significantly more alkaline than pH 5 5 at all hours ranging between pH 4·13 (± 259) and pH 5 42 (± 249)

A further demonstration of group variations is afforded by the comparison of the number of hours when pH values more alkaline than pH 3 5 were recorded. Patients with chronic duodenal ulcers were achlorhydric for a mean of 6 26 hours (± 1 131), with chronic gastric ulcers for a mean of 9·76 hours (± 1 314) and with acute ulcers for a mean of 17 95 hours (± 1 229) The application of Student's 't' test to these data shows highly significant differences between the patients with the acute and those with *chronic duodenal ulcer* (*t* = 3 526, *n* = 75 *p* = <0·001) and significant differences between the patients with acute and those with chronic gastric ulcer (t = 2 741 n = 57 p = <0·01) There is no significant difference between those with chronic duodenal ulcers and those with chronic gastric ulcers (t = 1 229, n = 50, p = <0·3)

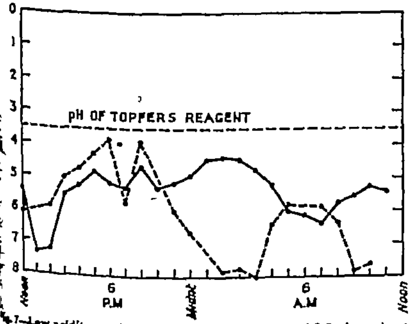

Fig 7—Low acidity persistently more alkaline than pH 3 5 throughout 24 hours in 2 patients bleeding from acute peptic ulcer

A second gastric analysis was made in 45 patients some weeks after hæmorrhage had ceased. High night acidity persisted in 10 of 12 patients who had originally shown this type of secretion pattern. Nocturnal neutralisation was again demonstrated to be a phasic phenomenon (Watkinson 1951) disappearing in 5 of 7 patients in whom the analysis was repeated. Return of acid secretion occurred in 20 of 23 patients initially achlorhydric at the time of hæmorrhage Fig 10 demonstrates this change in 2 of these patients.

Discussion

The difficulty in correctly diagnosing the cause of the hæmorrhage has been recognised in previous reports dealing with hæmatemesis, especially in the acute stages. We feel that hourly gastric aspiration facilitates diagnosis. The inadequacy of present diagnostic methods assumes considerable importance when we attempt to

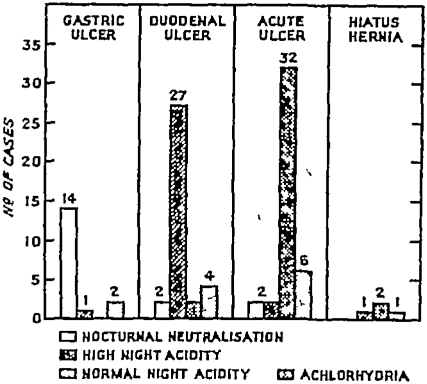

Fig 6—Relation of secretory patterns to ultimate diagnosis. Most of the gastric ulcers showed nocturnal neutralisation, whereas high acidity preponderated among patients with duodenal ulcer A significant proportion of patients with acute ulcer had achlorhydria.

assess the significance of an abnormally acid gastric secretion, and it must clearly bear on the validity of our conclusions in this report. Radiological and operative confirmation is forthcoming in patients with chronic gastric and duodenal ulcers but not in those with acute ulcers. Thus Needham and McConachie (1950) could give only an approximate estimate of the proportion of their hæmatemesis patients who had bled from acute peptic ulcer A high standard of diagnosis has been achieved by Tanner (1950) and Avery Jones (1952) largely by early gastroscopy combined with surgery and radiography Similar detailed investigation has been used in the present series, in which the distribution of the types of ulcer resembles that of the larger series reported by these workers

The mortality has been low only 3 patients dying of the 105 treated (2 9%): 1 in the fourth postoperative week from pulmonary embolism 1 on the fifth day from coronary thrombosis necropsy revealing in addition wide dissemination of carcinoma from a primary growth in the lung while the death of 1, a man of 88 could fairly be attributed to hæmatemesis, though carcinomatosis and chronic lung disease were important contributing causes. The mortality rate was not bad compared with the larger series of Avery Jones (1952) and Tanner (1950) but the numbers are small

This procedure allows of the prompt recognition of recurrence or continuance of bleeding When the physician is guided by his observations of the pulse rate and blood pressure, resuscitative measures are only too often applied tardily We have made it a rule that the nurses inform the house-officer when the aspirated specimens reveal recurrence of bloodstaining whatever the

TABLE III—RELATION OF SECRETION PATTERN TO FINAL DIAGNOSIS

Secretion pattern	No. of patients	No. with correct diagnosis	No with incorrect diagnosis	Difference	S.E. of difference of proportion
Nocturnal neutralisation	18	14(77 8 %)	4	0 556	0 113
High night acidity	31	27(87 1%)	4	0·742	0 103*
Achlorhydria	36	32(88 9%)	4	0 778	0 101
Total	85	73(85 9%)	12	0 717	0·075

Results significant.

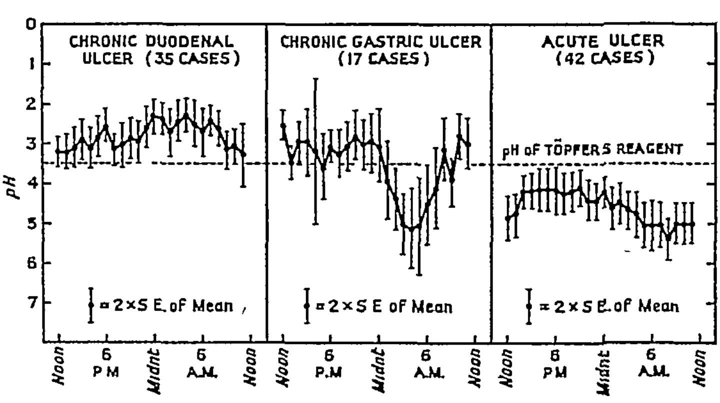

Fig 9—Mean hourly pH values with standard error Note highest nocturnal acidity with chronic duodenal ulcers and contrast with low nocturnal acidity with chronic gastric ulcers With acute ulcers mean pH values are significantly more alkaline than pH 3 5 at all hours.

clinical state of the patient is judged to be , thus the necessary preparations for transfusion can be made and treatment planned in advance In some patients the site of the hæmorrhage can be deduced from the association of continuing melæna with clear aspirated specimens The simple bedside observation of bloodstaining can provide reliable information both about recurrent bleeding and ulcer site, and with Kinsella (1950) we advocate its wider application

The changes observed in intragastric pH immediately after hæmorrhage have been of diagnostic value in 73 of the 85 patients in whom the secretion patterns were abnormal The finding of high night acidity facilitated accurate diagnosis in 27 of the 35 patients with chronic duodenal ulcers, this secretion pattern being usual in ulcers of this type uncomplicated by hæmorrhage Nocturnal neutralisation was observed in 14 of 17 patients with chronic gastric ulcers, a higher proportion than is commonly found with the uncomplicated lesion (Watkinson 1951), and again providing diagnostic information in a significant number We have come to attach great importance to the presence of achlorhydria, because 32 of the 36 patients with achlorhydria were finally classed as having an acute ulcer These results enable a more confident assumption to be made of the cause of the bleeding than would otherwise have been possible, especially in hæmorrhage from acute peptic ulcer, where the recognition of achlorhydria provides an indication for continued medical treatment,

We have been fortunate in the surgical assistance at our disposal, for of the 19 patients submitted to emergency gastrectomy only 1 died—in the fourth postoperative week from pulmonary embolism Severe recurrent hæmorrhage may demand operation even though a firm preoperative diagnosis of acute peptic ulceration has been made, based on the finding of achlorhydria This happened in 5 patients in whom operation verified the diagnosis and to whom a total of 73 pints of blood had been transfused before operation was advised Optimal conditions for successful surgery require an early decision in suitable patients, particularly those acknowledged subjects of chronic peptic ulceration where bleeding has recurred We believe *that this method can aid in their* early selection

The finding of achlorhydria in bleeding acute ulcer has not previously been described, the mechanism of its production is far from clear and many possible factors merit consideration Neutralisation of the stomach contents with blood appear of first importance, but the aspirated specimens were bloodstained as commonly with chronic as with acute ulcer Further, wide fluctuations in intragastric pH were observed despite uniformly bloodstained specimens, as is shown in fig 2, where the pH varied between pH 1 6 and pH 8 0, although all the specimens contained fresh blood

The *introduction of blood into the normal* stomach has various effects The isolated instillation of a large quantity produces only a short-lived achlorhydria, but the repeated introduction of moderate amounts causes a more uniform depression of acid secretion approximating to achlorhydria This observation suggests that the achlorhydria accompanying bleeding acute ulcer results from long continued oozing of blood from the submucosal vessels, in contrast to the more dramatic but isolated event of arterial bleeding in chronic ulcer

TABLE IV—RELATION OF ACHLORHYDRIA TO CLINICAL SEVERITY

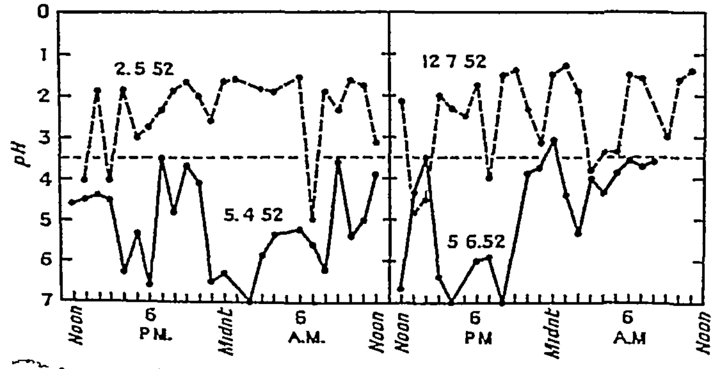
Severity	Chronic ulcer		Acute ulcer		Difference	S.E. of difference of proportion
	Achlorhydric	Not achlorhydric	Achlorhydric	Not achlorhydric		
Severe	1	14	12	3	0 733	0 156*
Moderate	1	20	13	2	0 719	0·164*
Mild		16	7	5		
Total	2	50	32	10	0 796	0 051*

* Results significant.

The effect of shock with accompanying fluid depletion and hypotension cannot be held entirely responsible for the genesis of achlorhydria A clinical assessment of severity on admission proved more satisfactory than a comparison of the amounts of blood transfused to each group, which, besides indicating the requirements of resuscitation necessary on admission, reflected also the number and severity of recurrent hæmorrhages If the numbers of patients with achlorhydria and either acute or chronic ulcer are studied in relation to the clinical severity on admission (table IV), it will be seen that, at all degrees of severity, the proportion showing achlorhydria was far higher among patients with acute ulcer than among those with chronic ulcer this difference being significant

The influence of plasma bicarbonate and blood urea levels on gastric secretion has been investigated by Apperly (1936) and Conway (1952) These levels were estimated many times in the present series and appeared in no way related to the abnormal secretion pattern obtained.

There remains the hypothesis that a difference in secretion, between patients



of acid secretion in 2 patients with acute ulcers initially achlorhydric at time of hæmorrhage.

acute and patients with chronic ulcer is ultimately responsible for the changes observed The difference in age and sex incidence between the groups is well known, and mucosal differences may well be present. Rodgers and Avery Jones (1938) have shown that acute ulcers are often accompanied by atrophic gastric mucosa, observed at gastroscopy, and hypochlorhydria as judged from a Rehfuss test-meal given at an unspecified time after hæmorrhage. The findings of Vanzant et al. (1932) who demonstrated an increasing incidence of achlorhydria with advancing age, might suggest that age and sex are concerned in the production of achlorhydria. Of the 16 males with acute ulcer and achlorhydria 15 were aged less than 60 and 9 less than 45 Of the 16 females with acute ulcer and achlorhydria 10 were aged less than 60 and 6 less than 45 These figures do not suggest that in these patients achlorhydria was related to age

Though the mechanism of the secretion variations remains unexplained, it is thought that gastric aspiration in the acute stages of gastroduodenal hæmorrhage has proved a safe and informative procedure and has aided materially in the management of the patients investigated

Conclusions

Early hourly gastric aspiration in 105 patients with hæmatemesis yielded valuable information and proved harmless

The bedside observation of bloodstaining in the aspirated specimens was useful because further hæmorrhage could be detected before other clinical criteria had indicated its presence; its absence sometimes aided localisation of the ulcer

A study of the acidity of aspirated specimens has shown that high nocturnal acidity is usual in bleeding chronic duodenal ulcer that nocturnal neutralisation is commoner in bleeding than in uncomplicated gastric ulcer and that achlorhydria is observed at the time of hæmorrhage in acute peptic ulceration, the acid often returning after several days observation

Achlorhydria in the acute stages of gastro intestinal hæmorrhage is thought to be an added indication for continued medical treatment.

Possible causes of the achlorhydria are discussed.

Our thanks are due to Prof. S J Hartfall Prof. R E Tunbridge, Dr Maxwell Telling and Dr R N Tattersall for allowing us to study patients admitted under their care and to Mr G Armitage Mr M. C Oldfield, Mr A. J C. Latchmore, Mr H. S Shucksmith, Mr D B Feather Mr H. Moore and Mr A. V Pollock, who operated on some of the patients studied. We should like to thank Mr D W Coulson for technical help Without the assistance of the nursing staff of the General Infirmary at Leeds and of St. James s Hospital Leeds, the investigation would not have been possible We are grateful to Professor Hartfall and Professor Tunbridge for their criticism and to Dr Maxwell Telling for his help in the preparation of this paper

LACTATION AND FLUID INTAKE

R S ILLINGWORTH
M.D Leeds, F.R C.P D.P.H., D C.H.
PROFESSOR OF CHILD HEALTH IN THE UNIVERSITY OF SHEFFIELD

B KILPATRICK
M.B., D C.H.
SENIOR HOUSE OFFICER (PÆDIATRIC), JESSOP HOSPITAL, SHEFFIELD

With assistance in statistics from J F SCOTT, M.A. Camb
RESEARCH ASSISTANT DEPARTMENT OF MATHEMATICS, UNIVERSITY OF SHEFFIELD

IT is customary to advise mothers in the early days of the puerperium, and at other times if there is an insufficiency of milk, to drink a lot of fluid to increase the milk-supply It seemed to one of us (R. S I) that it was unlikely on physiological grounds, that mothers would produce more milk if they took more fluid than they felt the desire to take It seemed likely that thirst, often experienced when the baby begins to suck is nature s method of supplying fluid needs in lactation, and that additional fluid is unnecessary A controlled experiment was therefore planned, on the same lines as a previous investigation (Illingworth and Stone 1952) to decide this question.

TABLE I—NUMBERS OF BABIES IN FORCED FLUID AND ORDINARY FLUID GROUPS IN DIFFERENT BIRTH WEIGHT CLASSES

Birth weight class (¼ oz. units)	Forced fluid group		Ordinary fluid group	
	Wards 1 and 3	Wards 2 and 4	Wards 1 and 3	Wards 2 and 4
350 (5 lb 7½ oz.)–399	5	4	6	5
400 (6 lb 4 oz.)–449	8	18	8	13
450 (7 lb ½ oz.)–499	22	10	22	23
500 (7 lb. 13 oz.)–549	13	7	13	9
550 (8 lb 9½ oz.)–599	6	8	4	1
600 (9 lb 6 oz.)–649	1	2	1	—
650 (10 lb. 2½ oz.) or more	1	—	1	—
Total	56	49	55	51

Method of Study

Maternity cases are nursed on two floors in the Jessop Hospital Each floor is divided into two wards, each ward being under the charge of one sister Two pædiatricians one on each floor, are responsible for the care of the babies with one pædiatric registrar or senior house-officer It was felt that there might be unrecognised differences in the management of lactation in the various wards so it was arranged that in one ward upstairs and one ward downstairs the mothers were asked to drink at least six pints of fluid a day from the first day onwards, with instructions to continue doing so when they returned home. In the remaining two wards one upstairs and one downstairs, no mention

TABLE II—COMPARISON OF BIRTH WEIGHTS, FLUID TAKEN BY MOTHERS PARITY, AND INCIDENCE OF BREAST FEEDING IN TWO WARDS

—	Average birth weight (¼ oz. units)	Average daily amount of fluid taken by mother (oz.)	Percentage of multiparæ	Percentage of babies fully breast-fed	
				On discharge	At age of 1 month
Forced-fluid group					
Wards 1 and 3	485	105·2	27·3	81·8	70·4
Wards 2 and 4	480	110·0	20·4	83·7	73·3
Ordinary-fluid group					
Wards 1 and 3	482	66·8	29·1	87·3	81·0
Wards 2 and 4	465	71·6	19·0	86·3	70·0

TABLE III—AMOUNT (OZ) OF FLUID TAKEN BY MOTHERS IN EACH OF FIRST 9 DAYS

—	Day								
	1	2	3	4	5	6	7	8	9
Ordinary-fluid group	61 0	69 0	67 9	67 1	67 8	71 4	73 1	73 3	70 2
Forced fluid group	85 0	102 8	108 8	109 0	110 7	113 4	114 3	115 1	110 0

at all was made about fluid intake, even if there were an insufficiency of milk, the mothers being left to take what they desired Only full-term babies were included in the study, but otherwise there was no selection of babies, all being included. When 50 complete records had been obtained in each pair of wards, the arrangement was to be changed over, so that the pair of wards in which fluids had been pushed now allowed the mothers to take only what they desired, and vice versa

The following records were kept the weight of the baby at birth, the weight on the 3rd, 5th, 7th, and 9th days and at the age of 1 month, the amount obtained by test feeds throughout the 8th day, added to that which was expressed after each feed, the amount of fluid taken each day by the mother in the first 9 days, and the incidence of full breast feeding, complementary feeding, and artificial feeding in hospital and at the age of 1 month

TABLE IV—GAIN IN WEIGHT ON 9TH DAY IN RELATION TO BIRTH WEIGHT

Birth weight group	Forced fluid group		Ordinary fluid group		Student's t test for difference between means
	Mean weight above birth weight (oz)	No of babies	Mean weight above or below birth weight (oz)	No of babies	
A	+0 07	22	+1 26	19	0 88
B	−1 00	35	−1 15	47	0 09
C	−2·03	27	−0 90	26	1 00

In all, 106 mothers were left to drink only what they desired (the “ ordinary-fluid group ”), and 104 mothers were asked to take at least six pints a day (the “ forced fluid group ”)

For part of the study the babies were divided into three birth-weight groups, as follows

Group A, birth weight less than 6 lb $13^{1}/_{4}$ oz

TABLE V—AVERAGE GAIN IN WEIGHT OF BABIES BY 3RD, 5TH, 7TH, AND 9TH DAYS

Day	Forced fluid group		Ordinary fluid group		Student's t test for difference between means
	Mean weight above or below birth weight (oz)	No of babies	Mean weight above or below birth weight (oz)	No of babies	
3	− 7 99	95	− 7 93	101	0 15
5	− 6 18	95	− 5 49	101	1 27
7	− 3 77	92	− 3·05	97	1 21
9	− 1 11	84	− 0 58	92	0 78

Group B, birth weight from 6 lb $13^{1}/_{4}$ oz to 7 lb 13 oz inclusive

Group C, birth weight greater than 7 lb 13 oz

COMPARABILITY OF THE TWO GROUPS

Birth weight—The birth weights of the babies studied were shown to be comparable (tables I and II) in the two groups of wards

Other Data—Table II shows that the parity of the mothers, the incidence of breast-feeding, and the amount of fluid taken were comparable in the two groups of wards Since there is no significant difference in these data from the two wards, the results from the two ward can henceforward be combined

Results

Amount of Fluid Taken—The average amount o fluid taken by the 106 mothers in the ordinary flui group was 69 1 oz, and by the 104 mothers in th forced-fluid group 107 5 oz Table III shows the averag amount taken by the mothers in each of the first 9 day We have no records of the amount of fluid taken by th mothers on return home Any such figures woul inevitably be inaccurate

TABLE VI—CORRELATION COEFFICIENTS BETWEEN AVERAG DAILY AMOUNT OF FLUID TAKEN AND GAIN IN WEIGHT 5TH AND 9TH DAYS

—	Day 5		Day 9	
	Coefficient	Number	Coefficient	Numbe
Ordinary fluid group	+ 0 12	101	+ 0 02	92
Forced fluid group	− 0 09	95	− 0 16	84

Gain in Weight—Table IV shows the gain in weigh in the two groups in relation to the birth weight Ther are no significant differences in any of the three birt weight groups A, B, and C When similar tables ar calculated for the weight gains by other days, there i again no significant difference, nor is there an difference when all the babies are classed togethe irrespective of their birth weight (table V) The fac that the number of babies studied on the 7th and 9t days is smaller than on the 3rd and 5th days is due t the necessity of excluding figures for gain in weight i a complementary feed was given Complementary feed were not given before the 6th day

Correlation Between Gain in Weight and Amount o Fluid Taken—Table VI shows the correlation betwee the gain in weight on the 5th and 9th days and the average daily amounts of fluid taken up to those days. There is apparently no linear relationship between the amount of fluid taken and the weight gain, and even when both groups are taken together no relationship of any kind exists Table VII shows that there is no significant difference in the gain in weight of the babies in the two groups at the age of 1 month in relation to their birth weight

TABLE VII—AVERAGE WEIGHTS OF BABIES AT AGE OF 1 MONT

Birth weight group	Forced-fluid group		Ordinary fluid group		Student's t test for difference between means
	Mean weight at 1 month (oz)	No of babies	Mean weight at 1 month (oz)	No of babies	
A	123 8	17	125 1	20	0 37
B	141 4	35	140 2	44	0 54
C	156 1	28	158 8	19	0·62

Test Feed (8th day)—Table VIII shows the results of test feeds in the mothers in the two groups. The only difference of significance is that in group C (the largest babies) More milk was produced by the mothers in the ordinary fluid group than in the forced-fluid group

TABLE VIII—TEST FEEDS FOR FORCED AND ORDINARY FEEDING

Birth weight group	Forced fluid group		Ordinary fluid group		Student's t test for difference between means
	Mean test feed (oz)	No of babies	Mean test feed (oz)	No of babies	
A	15 28	25	14 97	24	0 21
B	15 02	42	15 19	54	0 59
C	15 20	37	18 26	28	2 63*

* Result significant at 5% level.

TABLE IX—CORRELATION COEFFICIENTS BETWEEN AVERAGE DAILY AMOUNT OF FLUID TAKEN AND TEST FEED

—	Correlation coefficient	Number
Ordinary fluid group	+ 0 15	100
Forced-fluid group	− 0 20*	104

* Result significant at 5% level.

Correlation between Amount of Fluid Taken and Test Feed.—Table IX shows the correlation between the average daily amount of fluid taken by the mothers and the result of the test feed on the 8th day The correlation coefficient in the forced fluid group is just significantly negative This seems to suggest that there is a stage when too much fluid may have a detrimental effect on the supply of milk Both groups were combined to test for a curvilinear regression of the test feed on the amount of fluid taken but the result was not significant

Incidence of Full Breast-feeding on Discharge and at Age of 1 Month.—Table X shows that there is no significant difference in the two groups

Discussion

TABLE X—NUMBERS AND PERCENTAGES OF BABIES FULLY BREAST FED ON DISCHARGE, AND AT AGE OF 1 MONTH

—	Fully breast-fed	
	On discharge	At age of 1 month
Forced-fluid group	86/104 (*82 7*%)	64/89 (*71 9*%)
Ordinary fluid group	92/106 (*86 8*%)	69/92 (*75 0*%)

This investigation showed that not only does the forcing of fluids have no beneficial effect in increasing milk production, but also that it may have a harmful effect and reduce it. We therefore feel that the widespread custom of trying to persuade mothers to drink large quantities of fluid during lactation should be abandoned.

After completion of the investigation one of us (R S I) searched 48 volumes of the *Quarterly Cumulative Index Medicus* for other work on this subject and could only find a single investigation described in two papers by Olsen (1940 1941), who pointed out that, if it were true that forced fluids increased milk production one might also expect a corresponding increase of other body secretions, such as tears and saliva, when additional fluids are taken, this is not known to happen He remarked that there is no evidence that cows produce more milk when given extra water to drink Olsen made a careful study of 13 nursing mothers, giving them widely varying quantities of fluid, from 600 ml to 3775 ml a day, and doing daily test feeds to determine whether there was any correlation between the amount of fluid taken and the amount of milk produced. The quantity of fluid was then changed several times in these mothers, so that those who had been given large amounts of fluid were given very small amounts, and vice versa. There was no correlation at all between the amount of fluid taken by the mothers and the amount of milk produced. Five mothers became very thirsty on restricted fluids, but there was no decrease in the quantity of milk produced, and in 1 there was an increase Olsen concluded ' Forced excessive drinking is therefore neither necessary nor as a rule, beneficial as far as the nursing is concerned, and may even be harmful ' Our investigation adds support to Olsen's views.

Morrison (1952) mentions two other papers on the subject. Macy et al. (1930) found no correlation between milk volume and fluid intake in 3 subjects. Lelong et al. (1949) found no significant difference in the milk produced by a woman in a 10-day period in which 1322 ml. water was given per day and in an 11-day period in which the average water intake was 445 ml. There was no difference in the percentage of fat, protein, or carbohydrate in milk in the two periods

Summary

A controlled investigation was made on the relati ship of fluid intake to the amount of milk produced 210 mothers in a maternity unit.

106 mothers were given no instruction about h much fluid they should take, being left to drink w they wanted. The average daily amount of fluid dr by them was 69 1 oz.

104 mothers were instructed to take at least 6 p of fluid a day ; the average daily quantity taken them was 107 5 oz

The gain in weight of the babies, the result of t feeds, and the incidence of full breast-feeding w observed, the babies being divided into three birth wei groups

There was no evidence that the forcing of fluids h any beneficial effect on lactation On the contra there was evidence that more milk was produced mothers who only drank enough to satisfy their needs.

When the amount of fluid taken by all the moth was correlated with the test feeds, there was a significa negative correlation coefficient in favour of letting t mothers satisfy their fluid needs without being asked take more fluid.

The practice of instructing lactating women to dri large quantities of fluid should be abandoned Th should merely take enough to satisfy their own desires.

We wish to thank Miss M. J W Taylor, matron of t Jessop Hospital, and all the nurses and sisters who so willin coöperated in the investigation, which would have be impossible without their help We also wish to thank Dr Colver pediatrician, some of whose patients were includ in the study

INTENSIFIED ELECTROCONVULSANT THERAPY

REVIEW OF FIVE YEARS EXPERIENCE

R J RUSSELL
M.R C.S.
SENIOR ASSISTANT MEDICAL OFFICER

L G M. PAGE
M.R.C.S
DEPUTY MEDICAL SUPERINTENDENT

R L JILLETT
M B Lond
PSYCHIATRIC REGISTRAR

THREE COUNTIES HOSPITAL ARLESEY, BEDS

IN the five years since two of us described intensifie electroconvulsant therapy (Page and Russell 1948) w have treated more than 3500 further cases involvin more than 15,000 treatments.

Many critics seem to have a wrong conception of th method and believe that the patient receives to separate treatments in one day We therefore emphasis that the course normally consists of one treatment daily and is not given twice a day except in the severest case

The method originally consisted in giving an initia stimulus of 150V for one second. This stimulus wa immediately followed by seven further stimuli of on second each at 150V at intervals of half a second Th number of extra stimuli was increased by one at subsequent daily treatments, up to ten on the fourth day

More recently we have increased the number of extra stimuli, and aim to give sufficient in each case to maintain the tonic phase long enough to take the place of, and eliminate, the clonic phase of the fit The number required varies with different patients, and is usually between eight and fifteen The lower number is sufficient in an elderly patient, whereas a young schizophrenic may require fifteen or more The elimination of the clonic phase may also be achieved with a continuous stimulus of from ten to fifteen seconds, but we have found that the interrupted stimuli are more effective clinically

Contrary to what one would expect, these extra stimuli do not increase the severity of the fit but render it smooth and shorter

The daily repetition of the treatment until the symptoms have cleared is an essential part of the method

It has been stated by some critics of intensive electroconvulsant therapy, without any experience of the method, that it is dangerous and causes "cerebral damage" In our experience it is less dangerous than ordinary electroconvulsant therapy The risk of fractures is much less, since the clonic phase is eliminated in most cases, and for this reason we only use "muscle relaxants" in those few cases where a known risk of fracture exists We have seen no clinical evidence of "cerebral damage" following the normal use of intensive electroconvulsant therapy The degree of amnesia and confusion following treatment varies from case to case, but it is no greater than that following a comparable number of ordinary electroconvulsant treatments

The indefinable fear of electroconvulsant therapy which so many patients experience after the ordinary treatment is almost unknown after the intensive treatment We believe this is because subconvulsive stimuli are impossible with intensive electroconvulsant therapy, and it is now rare for a patient to object to a further course of treatment when this is required

Treatment of Depressives

The depressive case undoubtedly shows the best response to all forms of electroconvulsant therapy, and provides a suitable basis for comparison of methods We are indebted to many other hospitals and psychiatrists who have given us data for this comparison

An important factor is the interval between treatments Most users of ordinary electroconvulsant therapy appear to favour intervals of two to seven days, and it is significant that the shorter interval gives improved results judged by the lower number of treatments required (table I)

TABLE I—EFFECT OF INTERVAL BETWEEN TREATMENTS

Type of electroconvulsant therapy	Frequency of treatments	Usual no of treatments required per case of depression
Ordinary	1 a week	10–15
	2 a week	7–10
	3 a week	6–8
	Daily	5–7
Intensified	Daily	3–4

The degree or depth of depression in each case determines the number of treatments required Whereas two intensive treatments are sufficient in a mild depressive, a severe agitated melancholic may require as many as six or seven daily treatments It is in these severe cases that intensive electroconvulsant therapy shows to particular advantage, and we have seen many such cases that have failed to respond to ordinary electroconvulsant therapy which have successfully responded to intensive treatment

In our original series of cases the average number of treatments per case for all depressives was 3 2 This figure has now risen slightly to nearly 4 per case, because we find that giving one extra treatment after the depression has apparently cleared assists in preventing relapses

Skill and experience are required to judge when treatment should be stopped, and we find that, when in doubt, it is well to give one more treatment to prevent relapses.

Each case should be judged individually, and no fixed number of treatments should ever be contemplated.

We find that the predominantly exogenous and predominantly endogenous types of depression respond equally well to intensive electroconvulsant therapy, but the exogenous type usually requires slightly more treatments per case Similarly, the patient at the beginning of a depressive phase requires more treatments than one near the end of a depressive phase Since a good response is almost a certainty with intensive electroconvulsant therapy there seems to be no justification for leaving a patient to suffer days of depression while waiting for the declining phase

We treat most of our mild and moderately severe depressives as outpatients, and, since they require only three or four treatments, it is possible for them to return to work within a week or less of the start of treatment.

Puerperal Psychosis

TABLE II—RESULTS OF DIFFERENT TREATMENTS IN PUERPERAL PSYCHOSIS

Therapy	No of cases	No of deaths	Average stay in hospital (weeks)	No remaining in hospital	Average no of treatments per case	No. of cases relapsing	Failures
Other than electro convulsant	41	5	110	7	—	3	36·6%
Ordinary electro convulsant	7	0	27	1	11	2	42 8%
Intensive electro-convulsant	54	0	12	0	5 5	2	3 7%

A dramatic change has taken place in the prognosis of puerperal psychosis with the introduction of intensive electroconvulsant therapy We have treated 54 such cases and have compared them with the records of 41 similar cases before the days of electroconvulsant therapy and with 7 cases treated with ordinary electroconvulsant therapy (table II) All these patients were admitted to hospital within three months of parturition

We do not consider that puerperal psychosis is a separate entity, but believe it is a mental breakdown due to antenatal and postnatal stresses in a psychotically predisposed person

Before the introduction of electroconvulsant therapy 5 of 41 patients died and 7 are still in hospital as chronic psychotics after more than fourteen years Of those discharged the average length of stay in hospital was more than two years

Only 7 patients were treated with ordinary electroconvulsant therapy before the development of intensive treatment in 1946 These 7 patients show some improvement over those not treated by electroconvulsant therapy, but 1 has remained in hospital as a chronic case, and the average stay in hospital was still twenty seven weeks.

With intensive electroconvulsant therapy there have been no deaths, and none of the patients remains in hospital The average stay in hospital for the whole 54 patients was twelve weeks, but 2 of them were in for just over a year If these 2 cases are omitted, the average stay was seven weeks

Table II also shows the number of cases in each group that relapsed and were readmitted to hospital within two years of original discharge The failures are expressed as a percentage of each group, and include relapses, deaths, and those remaining in hospital The apparent high percentage of failures with ordinary electroconvulsant therapy is undoubtedly due to the small number of

, and would probably have been about 25% with
ger number

e number of intensive treatments given varied
een two and ten per case, with an average of 5 5
ared with the 11 per case with ordinary electr
ulsant therapy Treatment was begun within
ty four hours of admission to hospital and in 3 cases
irst treatment was given within forty-eight hours of
ntion.

lphonamides or antibiotics were not used in any of
ases.

e deaths before the use of electroconvulsant therapy
ar to have resulted from exhaustion due to the
nts' overactivity and inability to take fluids and
shment. These factors are readily overcome by
sive electroconvulsant therapy

e believe that early intensive treatment is important
ese cases because the early removal of psychotic
toms seems to prevent the development of chronic
hosis.

Schizophrenia

ulin-coma therapy has been continuously practised
is hospital for eighteen years. Looking back over
many schizophrenics of all types that have been
ed with insulin coma, one realises how disappoint
ineffective this treatment has been when the cases
ollowed up for five or more years Undoubtedly
results are seen occasionally in carefully picked
but for the whole group the most one can expect
emission of up to two years. These remissions may
peated with further courses of insulin in some cases,
he ultimate prognosis is very poor

ith this in mind we have during the past five
, treated most of our schizophrenics with intensive
roconvulsant therapy

ily treatments are started as soon as the patient is
tted and we find that acute schizophrenic symptoms
be rapidly cleared with four to seven treatments in
cases. Where patients have lost weight the
sive electroconvulsant therapy is immediately
wed with a course of modified insulin therapy to
ove the physical condition

ere appears to be no satisfactory way to present the
ts of treatment of schizophrenia statistically but our
ession after five years is that the results of combin
of intensive electroconvulsant therapy and modified
in therapy are as good as, and possibly superior to
e obtained previously with insulin coma alone

ny of the mild schizophrenics without any physical
ioration have been treated as outpatients with
sive electroconvulsant therapy alone This has
led many to continue a useful economic life for
ral years, with maintenance treatments at intervals
x to twelve months when necessary

Chronic Psychosis

e have used intensive electroconvulsant therapy
nsively for chronic psychotics, and particularly good
lts have been obtained with the disturbed and
ted types. We estimate that the destruction rate of
ing bedding, windows, &c. is now less than 20%
he rate before the introduction of electroconvulsant
apy Similarly, the number of patients now able to
nd hospital entertainments and recreations has
tly increased.

he use of protection rooms and seclusion is now
paratively rare, and is limited to the short interval
ween the patients' outburst and their receiving
tment. Tube-feeding and the use of special clothing
e been eliminated, and the strain on a depleted nursing
f has been noticeably decreased.

Ethics of Electroconvulsant Therapy

o have electroconvulsant therapy is a major event in
tient's life, and it is too easy for the operator to regard
it as a routine affair We think it very important that no patient should ever see or hear other patients undergoing treatment. We deplore the use of the term "shock treatment" and always describe it simply as "electrical treatment" to patients and their relations.

Patients are very ready to spread alarming tales of the treatment among each other Hence we always prefer to begin the treatment of new cases within twenty four hours of admission to hospital. Since the physical contra-indications for electroconvulsant therapy are now so few, it is seldom that this routine cannot be adhered to

Cerebral Stimulation

During the last year cerebral stimulation has been used as a "counter stimulus" immediately following intensive electroconvulsant therapy in 43 cases of depression

This stimulus is applied in the same way as electroconvulsant therapy and consists of a unidirectional interrupted direct current at 50 cycles per second With a strength of 5–7 mA applied for two to three minutes the effect is to reduce considerably postoperative amnesia and confusion It also appears to have a calming influence on the patient and thereby reduces anxiety and tension.

There seems to be a tendency for "counter stimulus" to reduce the effectiveness of electroconvulsant therapy slightly and we find that it is often necessary to give one more electroconvulsant treatment than would have been expected if "counter-stimulus" had not been used Counter-stimulus is most useful in depressed patients of high intellect who are anxious to return to work as soon as treatment is completed.

Counter-stimulus is definitely contra-indicated in schizophrenia and hysteria because the symptoms do not clear when it is used This suggests that the development of some amnesia is an important factor in the clearance of symptoms in cases other than depressives.

Conclusion

Intensive electroconvulsant therapy is not a new treatment but a technique of applying electroconvulsant therapy in those cases where it is indicated We believe its greater effectiveness over ordinary electroconvulsant therapy is due to the fact that larger stimuli are given in a shorter time

Many of those who have not seen the technique believe it to be a drastic form of treatment, but this fallacy is dispelled when the method has been observed. It seems that, apart from those visitors to whom we have demonstrated the technique, few have attempted it.

Patients appreciate intensive electroconvulsant therapy because it offers better results in a shorter time and has largely overcome the fear reaction to electroconvulsant therapy Electroconvulsant therapy should never be applied indiscriminately but properly applied it is probably the greatest advance so far made in psychiatry

Summary

Intensive electroconvulsant therapy with recent developments, is described

The effect of varying the frequency of treatments is discussed.

The comparative results in the treatment of puerperal psychosis with intensive, with ordinary, and without electroconvulsant therapy are given.

The use of intensive electroconvulsant therapy in schizophrenia and in chronic psychosis is discussed

The use of "counter-stimulus" after electroconvulsant therapy is described.

Ectron apparatus, which we believe to be the only type suitable for intensive electroconvulsant therapy was used throughout our work, and we are indebted to Ectron Ltd., of Baldock, Herts, for the loan of a cerebral stimulator

FUMAGILLIN IN AMŒBIASIS

R Elsdon-Dew
M D Edin, F R S S.Af

A J Wilmot
D.M. Oxfd, M R C P

T G Armstrong
M A, M D Camb, M.R C P

From the Amœbiasis Research Unit, South African Council for Scientific and Industrial Research, and the Natal Provincial Administration, Durban

We have previously shown that antibiotics are useful in the control of the acute phase of amœbic colitis (Armstrong et al 1949, 1950, Elsdon-Dew et al. 1952) Though there is little doubt that this action has in the main been through the associated bacterial flora, there was some suggestion that some antibiotics might have a slight amœbicidal action

The isolation of fumagillin by Hanson and Eble (1949) quickly led to a study by McCowen et al. (1951) of its properties, including a lethal effect on *Entamœba histolytica* in vitro, with no apparent effect on the bacterial flora, and with a corresponding curative effect on experimental amœbiasis in animals These results were confirmed by Hrenoff and Nakamura (1951) using cultures in association with *Trypanosoma cruzi*

The application of fumagillin to human cases soon followed

Killough et al (1952), using up to 50 mg daily in 22 cases, in which 12 patients had no symptoms, 9 had mild gastro intestinal disturbance, and 1 had severe amœbic dysentery, reported parasitic clearance in all but the severe case, in which apparently a liver abscess developed

Anderson et al (1952) treated 20 chronically infected cases of amœbiasis with fumagillin, using a total divided dose of up to 100 mg in twelve days, and reported relapse in 6 out of 10 cases on a smaller dosage and in 1 out of 10 on a larger dosage They did not observe any signs or symptoms of intolerance

Steigmann et al (1952) treated two different series of cases with fumagillin In the first series, of 11 chronic and 4 acute cases, 4 patients given 200 mg daily were cleared of amœbæ but developed untoward symptoms, such as exfoliative dermatitis and psychosis, and 11 patients given 100 mg daily had moderate nausea with occasional vomiting, 3 of them developing a macular rash on the face and extremities All 15 were parasite free at the end of therapy, but 5 relapsed within three months. In the second series, of 25 cases, of 5 "carriers" given 150 mg daily for ten days 2 were parasite-free at the end of three months, of 10 "carriers" given 100 mg for ten days 7 were negative after three months, and in 10 active cases of amœbiasis treated with 120 mg daily for ten days there were 4 failures.

Present Series

Our unit has been active in the assessment of drugs in the treatment of amœbiasis A plethora of cases of acute amœbic colitis allows us to select patients for trial therapy on a strict and uniform basis, details of which have been reported elsewhere (Elsdon-Dew et al 1952) Assessment at the twentieth day is made on the following basis

Success —Symptom free, all ulcers healed, and no amœbæ found in stools

Possible Failure —Usually symptom free, one or more ulcers still open, but amœbæ not found in stools or in scrapings.

Absolute Failure.—Open ulcers still present and amœbæ still demonstrable

Removed from Treatment —Patients showing severe clinical deterioration were placed on therapy known to be effective Where this deterioration took place before the fifth day, such cases were not included in the series, but after the fifth day such cases are shown as "removed from treatment."

COMPARISON OF RESULTS OBTAINED WITH DIFFERENT DRUGS IN AMŒBIASIS

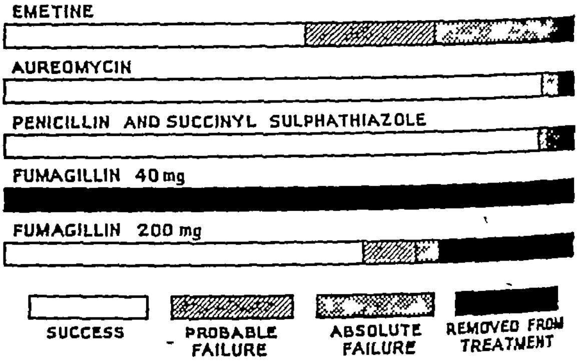
Treatment	No of cases	Success (%)	Probable failure (%)	Absolute failure (%)	Removed from treatment (%)	Total absolute failure (%)
Emetine	50	50 0	22 0	28 0		28 0
Aureomycin	52	92 3	3 8	1 9	1 9	3 8
Penicillin and succinyl sulphathiazole	50	92 0	2·0	4 0	2 0	6 0
Fumagillin 40 mg	7				100 0	100 0
Fumagillin 200 mg	48	62 4	6 3	4 2	27 1	31 3

Dosage and Toxicity

Two series of cases have been treated, one of 7 cases on fumagillin 20 mg twice daily for ten days, and one of 48 cases on fumagillin 50 mg four times a day for 10 days

Systematic laboratory examinations to assess possible toxicity were not made, but the patients complained of no untoward symptoms except an irritative fine desquamating rash on the face This happened only on the larger dosage of 200 mg a day

Of 49 patients who received fumagillin 200 mg a day 14 developed facial dermatitis, which appeared between the sixth and tenth days For this no treatment was given other than calamine lotion, and the fumagillin therapy was continued The dermatitis subsided spontaneously within five days after the end of fumagillin therapy



Comparison of results obtained with different drugs in amœbiasis.

Results

In the accompanying table and figure the results are summarised and compared with those obtained with emetine, with aureomycin, and with penicillin and succinyl sulphathiazole

Of the patients treated with fumagillin 40 mg daily, 3 were removed from treatment because of clinical deterioration before completing the course The remaining 4 patients all showed ulceration and parasites after completing treatment with fumagillin Assay, by the manufacturers, of the activity of the fumagillin remaining after this series had been treated, showed a 28% loss.

Of the patients treated with the larger dosage, 3 were removed from treatment on the fifth, sixth, and seventh days owing to clinical deterioration before completing their course, and because it was felt unjustifiable to withhold known effective treatment

At ten days from the start of treatment 28 cases were classified as successes and 10 as probable failures The remaining 7 were absolute failures with open ulcers and free forms of *E histolytica* and were removed from this series

Before final assessment at twenty-seven days from the start of treatment 2 further cases became absolute failures and were consequently given other treatment 2 cases persisted as probable failures with open ulcers and no parasites demonstrable As both patients complained of diarrhœa with blood and mucus they were treated with emetine, 'Diodoquin,' and phthalylsulphathiazole, with relief of symptoms One patient complained of severe diarrhœa with much blood and mucus at enty *days from the start of treatment*, *although no* ers or parasites were seen, the symptoms demanded her treatment, and the case was consequently removed om this series.

Of the remaining 33 patients 31 had no symptoms, ers, or parasites at twenty-seven days from the start treatment and were discharged from hospital 2 were mptom free and no ulceration was seen on sigmoid copy, but cysts of *E histolytica* were found in their ols. No other treatment was given, but unfortunately ese patients have not returned for follow up The rican is reluctant to return to hospital unless he feels . Consequently our follow up has been very inadequate

Conclusions and Summary

Fumagillin 40 mg daily was ineffective in controlling ute amoebic dysentery

Fumagillin 200 mg daily for ten days produced ults comparable to those obtained with emetine gr 1 ily for ten days but inferior to those obtained with reomycin 2 g daily for fifteen days.

The only toxic action observed was a mild facial rmatitis which only occurred with the larger dosage

These results apply only to acute ulcerative amoebiasis the African male

Our thanks are due to the Council for Scientific and Indus al Research and the Natal Provincial Administration for eir continued support, and to the Upjohn Company of lamazoo for supplies of fumagillin and for their ready operation in the assay of the remaining material

ACUTE SALT DEPLETION ASSOCIATED WITH THE NEPHROTIC SYNDROME

DEVELOPING DURING TREATMENT WITH A MERCURIAL DIURETIC

J R K. PREEDY

LONDON HOSPITAL

ALTHOUGH many toxic actions of mercurial diuretics re well known, those affecting the kidney have been nly rarely described Of these descriptions most relate o slight and transient toxic manifestations such as he finding of casts, leucocytes, or erythrocytes in the rine, and mild albuminuria (deGraff and Nadler 1942) nd it is not always clear to what extent these findings re due to the underlying disease. However two cases ith severe renal tubular involvement have been noted by Waife and Pratt (1946) and Bruno (1948) It was considered of interest to report the present case firstly because of the severe renal tubular damage found post mortem for which there is substantial evidence incriminating the mercurial diuretic 'Neptal and secondly because the patient presented with a severe sodium and chloride depletion similar to that found in a crisis of Addison's disease, associated with the clinical and biochemical picture of the nephrotic syndrome.

Case report

A woman aged 54 had been admitted seventeen months previously to the London Hospital with an anterolateral cardiac infarct, thought to be extensive on electrocardiographic evidence This was associated with some degree of left ventricular failure, shown by orthopnoea, and medium crepitations at both lung bases. On treatment with the mercurial diuretic neptal 2 ml. intramuscularly twice a week for the first week, and thereafter once a week symptoms disappeared in a few days. The blood pressure varied between 110/75 and 140/100 mm. Hg The urine on admission contained a haze of protein. This disappeared on the third day and frequent subsequent analyses revealed no abnormality Fifteen months previously the treatment with neptal was discontinued, and the patient was seen regularly thereafter in the outpatient department. After a month attacks of paroxysmal nocturnal dyspnoea occurred. These improved after treatment with neptal 2 ml. intramuscularly once a week, but did not disappear until the same injection was given twice weekly The patient remained symptom free on this treatment, leading a normal life for her age Occasional examination of the urine during this period revealed no proteinuria. There was no dietary restriction of salt the daily intake being estimated at about 5 g In all, 130 injections of neptal 2 ml were given in sixty-eight weeks. A week previously the patient had noticed progressive swelling of ankles and face particularly of eyelids, and felt very weak. This was followed two days later by vomiting two or three times a day accompanied by some anorexia. During this week two injections of neptal were given by the patient's family doctor with good diuresis after the first but not after the second injection. The second injection was given forty-eight hours before admission to hospital. No further relevant information was obtained from the previous, family, or social history

On examination the patient was obviously ill but coöperative with her mental state clear and no dyspnoea at rest She had a pale face and cyanosis of her lips, and of her hands and feet which were cold and clammy There was considerable oedema of legs sacrum, face, and arms. The blood pressure was not recordable The pulse was regular but scarcely palpable, pulse-rate 92 per min The jugular venous pressure was not visibly raised The apex beat was at the fifth left intercostal space in the anterior axillary line (as on the previous admission); the heart sounds were distant and no thrills or murmurs were detected. No abnormality was detected in the respiratory system, abdomen, or central nervous system.

Investigations —Electrocardiography showed evidence of old cardiac infarct. Radiography of the chest showed an opacity at the left base suggesting a small pleural effusion. The urine contained much protein, when it had been boiled at pH 4 and had stood for an hour nine-tenths of its original volume was occupied by precipitated protein. Microscopy of the deposit showed a few red cells, leucocytes, and granular casts. On culture the urine was sterile It contained urea 21 g per litre chloride 43 m.eq per litre, sp. gr 1 025 The plasma chloride level was 86·5 m.eq per litre, plasma-sodium level 108 m.eq per litre plasma-potassium 4 71 m.eq per litre blood urea level 75 mg per 100 ml. total plasma-protein level 4 1 g per 100 ml., plasma-albumin level 1·6 g per 100 ml. plasma-globulin level 2 5 g per 100 ml. blood-cholesterol level 570 mg per 100 ml. and hæmatocrit 54%

Treatment and progress —A daily total of $2^{1}/_{2}$ litres of sodium-chloride solution (155 m.eq of sodium chloride per litre) was given by mouth for two days, in addition to a semisolid diet and adequate amounts of water This the patient took well, with no further vomiting Her blood pressure became recordable at 90/60 mm. Hg on the second day In spite of this her condition had clearly deteriorated and the oedema had much increased. On the third day the plasma chloride level was 79 m.eq per litre, plasma-sodium level 120 m.eq per litre plasma-potassium level 4 37 m.eq per litre and hæmatocrit 57%. Urinary chloride in a random specimen was 10 5 m.eq of sodium chloride per litre An intravenous drip of sodium-chloride solution (155 m.eq of sodium chloride per litre) was set up and 10 ml. of adrenal cortical extract (Eucortone) was given intravenously every four hours. There was no obvious improvement after twelve hours. 750 ml of 6% dextran solution was then administered slowly by intravenous infusion. The patient's condition rapidly improved; her limb extremities became warm and pink for the first time and her blood pressure rose to 130/90 mm. Hg But the peripheral oedema had again increased Four hours later pulmonary oedema supervened, and death took place two days later No further blood for analysis could be obtained, owing to the oedema The twenty-four hour urine volumes for each day except the last three were about 1200 ml In the last three days the volumes diminished, the lowest being 300 ml on the last day of life The specific gravities varied between 1 005 and 1 025 Each specimen contained much protein.

Necropsy

Necropsy was done three days after death, the body being kept in the cold chamber The principal findings were confluent purulent bronchopneumonia, severe degeneration of the kidneys, and an old infarct of the myocardium Œdema of the feet, legs, and lumbar pad was noted

Heart —The lower four fifths of the anterior wall of the left ventricle and adjacent interventricular septum were replaced by fibrosis, the adjacent pericardial sac being obliterated by fibrous adhesions. The lumen of the lower half of the anterior descending branch of the left coronary artery was occupied by organised thrombus There was severe general atheroma of the aorta and its branches

Kidneys —Combined weight 319 g The subcapsular surfaces were smooth, the cortex swollen and greyish yellow, with congested straight interlobular vessels, there was slight blurring of the junction between cortex and medulla, the latter showing a few yellow streaks in the apices of the pyramids Small groups of petechial hæmorrhages mottled the pelvic mucosa The rest of the urinary tract appeared normal

Endocrine glands —All appeared normal apart from post mortem degeneration, with central softening, in the suprarenal bodies (combined weight 16 8 g) Microscopically there was abundant sudanophil lipoid in much of the suprarenal cortex, especially its deeper layers, the degeneration present appeared attributable to post-mortem changes The pituitary was microscopically normal

Spleen —There was diffuse congestion attributable, microscopically, to acute inflammation of the pulp

Liver —Parenchymatous degeneration and, microscopically, slight periportal fatty change, no congestion.

Microscopic Examination of Kidneys

The cortex was unevenly congested, some glomeruli being engorged and others bloodless In a good many of the glomeruli the capsular epithelium had undergone severe degeneration, with desquamation of the cells and the formation of collections of eosinophil flocculent debris in the capsular space In other respects the glomeruli appeared normal

Severe degenerative changes were found in the tubules, especially the convoluted segments The epithelium of the first convoluted tubules and of the descending thick part of the loops of Henle was pale, swollen, and finely vacuolated, in a few tubules the degeneration had proceeded to necrosis Stages of karyolysis and pyknosis were obvious The lumina were reduced and often contained eosinophil debris In frozen sections part of this vacuolation was accounted for by sudanophil doubly refractive droplets, presumably cholesterol esters, which were conspicuous in the basal part of these cells. Since stains for glycogen were negative, the remainder of the vacuolation was attributed to hydropic degeneration.

In the distal segments there was considerable desquamation of the epithelium, suggesting post-mortem degeneration. But in places it was clear that ante mortem degeneration had led to loss of the cells, since there was clear evidence of epithelial regeneration Thus, in these tubules, desquamation was accompanied by a flattened lining of basophilic cells in which the nuclei were unevenly distributed Bulky hyaline and granular casts occupied many of the lumina both here and in the collecting tubules, in a few of the second convoluted tubules there were collections of polymorphs A few leucocytes were also found in the thin loops of Henle, nuclear pyknosis and karyorrhexis affected the epithelium also at this level

The interstitial tissue was oedematous A few groups of lymphocytes lay beneath the kidney capsule and near large veins in the upper medulla Elsewhere an occasional polymorph was found Apart from hypertrophy and fibrosis of the intima of the arcuate and interlobular arteries there were no vascular changes

Discussion

The clinical features of this case up to a week before the patient's second admission are not remarkable A cardiac infarct sustained seventeen months previously was associated at the time with some degree of left ventricular failure This subsided with rest in bed and neptal injections The injections were subsequently discontinued Three months later, attacks of paroxysmal nocturnal dyspnœa supervened The attacks were well controlled with further injections of neptal twice weekly The patient remained symptom free on these injections for fourteen months No other treatment was given. There was no restriction of salt in the diet

However, the clinical features dating from the week before her second admission are unusual They can clearly be divided into two well-recognised syndromes (1) the syndrome of acute sodium and chloride depletion similar to that seen in the crisis of Addison's disease, with weakness, vomiting, thready pulse, low blood pressure, cold extremities, raised hæmatocrit, raised blood urea level, and lowered plasma sodium and plasma-chloride levels, but with a moderate concentration of chloride in the urine, and (2) the nephrotic syndrome commonly associated with type II nephritis (Ellis 1942), characterised by œdema of the legs, arms, and face, profuse proteinuria, lowered plasma-protein level, the albumin fraction being particularly affected, and a raised blood cholesterol level

A sodium and chloride depletion of the magnitude here observed could only have been caused by a loss of Na and Cl ions from the body Possible routes in this patient would be via the vomit and the urine However, the vomiting was not profuse, and the plasma-electrolyte levels did not suggest an electrolyte depletion due to vomiting, the Cl ion being less depleted than the Na ion. No obvious cause of vomiting as a primary symptom was found either clinically or post mortem It is much more likely that the vomiting was the result of a sodium and chloride depletion rather than the cause It will be noted that other symptoms preceded the vomiting by two days

It is therefore likely that sodium and chloride were lost by urinary excretion, and this is strongly supported by the finding of 43 m eq per litre of chloride in the urine on admission forty eight hours after the last neptal injection Possible causes of urinary loss of sodium and chloride are (1) Addison's disease, (2) the diuretic phase of acute tubular necrosis (Bull et al 1950), (3) "salt losing nephritis" (Thorn et al 1944, Joiner and Thorne 1952), and (4) the action of the mercurial diuretic Addison's disease can be immediately excluded by the normal plasma potassium level, the failure to respond to adrenal cortical extract, and the normal adrenal glands at necropsy The diuretic phase of acute tubular necrosis can similarly be excluded There was no previous anuria and no recognisable cause for anuria There was no subsequent polyuria (the urine-urea level was 21 g per litre on admission), and the electrolyte depletion affected mainly the Na and Cl ions, whereas in acute tubular necrosis K is usually also involved Previously reported causes of "salt losing nephritis" can be excluded by the necropsy findings

There remains the action of the mercurial diuretic It is well recognised that a sodium depletion can follow the use of mercurial diuretics (Schroeder 1949, Soloff and Zatuchni 1949), but it only seems to do so when the diuretics are given in conjunction with a low sodium diet (Schroeder 1949), with ion exchange resins, or when the diuretics are given daily, especially in elderly persons (Jaffe et al 1950) In the present case the diet was normal, salt was not restricted, no ion exchange resins were given, and the diuretic was not administered more often than twice weekly The sodium and chloride depletion here observed was far more severe than in most of the cases previously reported, and was associated with the nephrotic syndrome, which complicated none of those cases It therefore appears unlikely that the condition here observed is directly comparable with these simple low sodium states

In view of the presence of the nephrotic syndrome, the possibility must be considered that type II nephritis might be a contributory factor The onset of this disease ot, however, associated with a sodium and chloride etion of any magnitude

hese clinical features suggest that they may be ciated with a diffuse renal lesion, of which the main lence is in the tubules, and for which the mercurial etic might be responsible A predominantly tubular n could account for the renal loss of sodium and ride, from failure of adequate tubular reabsorption hese ions. The development of the nephrotic syn no is more difficult to explain Tubular necrosis due poisoning with inorganic mercurial salts does not lly produce this picture (Fishberg 1939, Volhard l). However, the occurrence of this syndrome due he action of an organic mercurial diuretic is not nded and must be regarded as a possibility

ome support for this view comes from previous unts of severe tubular damage attributable to curial diuretics, where profuse proteinuria and ma have been a feature clinically Two such accounts e been published by Bruno (1948) and Waife and tt (1946)

he case described by Bruno was one of heart-failure with al stenosis. The patient developed nausea vomiting and ma, together with proteinuria and chloride depletion while er treatment with a mercurial diuretic These findings e attributed to toxic nephritis due to the diuretic. ever the patient was a known diabetic and considerable rcapillary glomerulo sclerosis was found at necropsy It erefore doubtful to what extent the clinical features can ttributed to the diuretic.

aife and Pratt (1946) described a case of heart failure with ral stenosis in which the patient was treated with 28 ctions of 'Mercurophylline' in eight months. The patient denly developed oedema of the face and arms, profuse teinuria, and a raised blood urea level The extremities ame cold and the blood pressure unrecordable. Unfortu ely no plasma-electrolyte levels were reported, but the lings of cold extremities, low blood pressure and raised od urea level suggest sodium and chloride depletion. These kers diagnosed toxic nephrosis due to the mercurial retic, and their case appears very similar to ours.

The pathological evidence can now be considered The g interval between death and necropsy was responsible the considerable amount of post-mortem degeneration n on microscopy of the kidneys. This makes it ficult to assess accurately the degree of ante mortem ular degeneration However after due allowance has en made for this factor it is clear that there must have en severe degeneration and even necrosis of the tubule ithelium since evidence of regeneration was found the second convoluted tubules. Analysis, in fact, ggests that this part of the nephron was the most erely affected and this is supported by the focal lymorph infiltration of the lumina in these segments. t the proximal convoluted tubules were also involved was shown by the sudanophil lipoid in their cells It difficult to tell whether the other changes in the oximal convoluted tubules developed before or after ath.

Already published reports of cases in which renal ions are attributed to the use of mercurial diuretics in art-failure agree in describing severe degeneration of e tubule epithelium, sometimes advancing to necrosis osenthal 1933 Waife and Pratt 1946) with evidence regeneration (Sprunt 1930 Waife and Pratt 1946) alcification is sometimes mentioned as an important ature (Tarr and Jacobson 1932) but we have observed onspicuous calcification in the kidneys of young people ith rheumatic carditis and heart-failure who had never ad mercurial diuretics. The production of tubular egeneration by mercurial diuretics in advanced heart-ailure is extremely difficult to prove, owing to the well nown incidence of degeneration in untreated cases. But hen the degeneration amounts to necrosis, with clear vidence of regeneration and where there is evidence of mercurial intoxication from the examination of other tissues (Sprunt 1930, Rosenthal 1933 Waife and Pratt 1946) the likelihood that the lesion is due to the mercurial diuretic appears undeniable The problem in our case is easier because there was no evidence of congestive heart-failure either clinically or post mortem

Further evidence that the mercury ion in both inorganic and organic combination may cause anatomical lesions in the renal tubular epithelium is obtained from previous reports Page and Wilson (1940) have reported the cases of two patients who died on the seventeenth and eighteenth days after the use of a bladder wash of mercury oxycyanide. Microscopically the kidneys in these two cases were similar except for extensive calcification in one The glomeruli were normal, but there was severe degeneration of the epithelium throughout the tubules, with active regeneration

To elucidate certain observed features of human intoxication with organic mercury methyl compounds arising from their preparation as insecticides, Hunter et al (1940) treated rats and a monkey with these substances. Microscopy of the rats kidneys revealed normal glomeruli but severe dropsical and hyaline-droplet degeneration of the epithelium of the convoluted tubules, amounting in places to necrosis The lumina were often blocked by cellular debris There was some evidence of epithelial regeneration Re-examination of the monkey s kidney establishes that the glomeruli were normal Albuminous and dropsical degeneration was conspicuous in the proximal tubules. The distal tubules were more severely affected, with shedding of the epithelium and regeneration

The only finding in the present case that at all suggests type II nephritis is the presence of doubly refractive sudanophil lipoid in the proximal convoluted tubules Probably this was related to the raised blood-cholesterol level. It was not, however, a prominent histological feature, and in all other respects the picture differed from any known form of Bright s disease However glomerular changes in early type-II nephritis (nephritis mitis lipoid nephrosis) are slight and a pre-existing type-II nephritis with tubular necrosis superimposed, cannot confidently be excluded by microscopy

Although it appears unlikely that the sodium and chloride depletion observed in the present case would be responsible for the tubular necrosis, the possibility needs consideration Some evidence on this point can be obtained from an examination of the kidneys in Addison s disease

Although experimentally severe damage can be inflicted on the renal epithelium of rats by total adrenalectomy (Simpson and Korenchevsky 1936) there are no characteristic findings in the kidneys in human examples of Addison's disease (Allen 1952) Ten cases have been reviewed by us including some that had received adequate hormonal treatment and some untreated cases that came to necropsy in the early decades of this century The kidneys in these showed various degrees of parenchymatous degeneration, occasionally fatty involving the tubules diffusely and without special selection of the distal segments. Casts were rare and, when present consisted of a few hyaline deposits in the collecting tubules. In one example alone (an untreated case) was there evidence of regeneration in the distal convoluted tubules. There was no interstitial reaction in the cortex It is clear then, that in man severe sodium depletion can exist without the tubular changes observed in the present case, at least in Addison s disease.

The evidence both clinical and pathological therefore supports the view that the tubular necrosis and severe salt depletion in the present case was due to the mercurial diuretic neptal. In accounting for the nephrotic syndrome the recent onset of type II nephritis cannot be confidently excluded There is, however no positive evidence of this condition either clinical or histological

The low plasma protein level and the high blood-cholesterol level, together with the histological finding of lipoid in the tubular epithelium, does, however, suggest that the condition may have antedated the appearance of the œdema, which was present for only a week before admission

The coexistence of severe sodium and chloride depletion and the nephrotic syndrome is of particular interest Although severe sodium and chloride depletion from renal loss of these electrolytes also occurs in acute tubular necrosis and in "salt losing nephritis," in neither of these conditions is the depletion associated with the nephrotic syndrome Nor, in the development of the nephrotic syndrome, as in type-II nephritis, is the rapid accumulation of œdema usually associated with severe salt depletion

Summary

A case is reported in which acute sodium and chloride depletion, associated with the nephrotic syndrome, developed during therapy with the mercurial diuretic neptal for heart-failure

A severe renal tubular lesion was demonstrated histologically

Evidence is presented which suggests that the mercurial diuretic may have been responsible

We are indebted to Dr A. E Clark-Kennedy for permission to publish this case, and to Prof Clifford Wilson for valuable help and advice

SPUTUM DISPOSAL IN THE HOME

F J Baker
F.I.M.L.T, F.R.M.S
From the Bacteriology Department, Brompton Hospital, London

'Milsol' (Milton) is a hypochlorite solution containing caustic soda A H Walters (personal communication) has shown that sputum is dissolved in 15–30 seconds when added to this solution This quality suggested that milsol might provide a suitable means of disposal of sputum, especially for patients in their own homes The value of such a process would be greatly enhanced if the sputum was sterilised at the same time

Experimental Observations

Two experiments were performed, their object being (1) to measure the time required by milsol to kill *Mycobacterium tuberculosis*, and (2) to ascertain whether the bactericidal effect of the antiseptic was reduced by prolonged contact with the sputum In these experiments it was assumed that failure to obtain growth of *M tuberculosis* after 10 weeks indicated a bactericidal action

Experiment I

Method —Sputum known to contain large numbers of tubercle bacilli was collected from seven patients All the specimens were mixed together Of this mixture 5 ml. volumes were added to each of 44 sterile 1-oz. screw-capped bottles Of these bottles 4 were used as controls, they were liquefied with trisodium phosphate and inoculated on Lowenstein-Jensen medium, two slopes of this medium being inoculated from each bottle. To each of the remaining 40 bottles 20 ml of milsol was added rapidly, and the bottles were then shaken gently to dissolve the sputum The 40 bottles were divided into 5 groups

Group A, representing a "milsol contact time" of 15 minutes, were centrifuged for 15 minutes at 3000 r p.m. The supernatant fluid was discarded, and the small deposit was resuspended in 25 ml of sterile glass-distilled water After shaking, the contents were neutralised with 8% hydrochloric acid, using bromthymol blue as indicator The bottles were again centrifuged at 3000 r p.m After the supernatant fluid had been discarded, a few drops of tryptone water were added to each deposit, from which two Löwenstein-Jensen slopes were inoculated The slopes were incubated at 37°C for 10 weeks, and cultures were examined each week for evidence of growth

Group B, fifteen minutes after homogenisation, was treated in the same way as group A. This group represented a "milsol contact time" of about 30 minutes.

Group C represented a "milsol contact time" of 60 minutes.

Group D represented a "milsol contact time" of 90 minutes.

Group E represented a "milsol contact time" of 120 minutes.

A surface scum formed in all the bottles of groups C, D, and E Each scum was removed and mixed with 25 ml of sterile glass distilled water After centrifugation at 3000 r p m for 15 minutes each deposit was resuspended in 25 ml of sterile glass distilled water Centrifugation was repeated, and after the addition of a few drops of tryptone water films of the deposit were made for microscopical examination The remainder of the deposit was cultured on two Lowenstein Jensen slopes.

Results —The following results were obtained

Controls

Smears —Acid fast bacilli were present in smears from all specimens

Cultures —All the cultures were positive for *M tuberculosis* after 4 weeks' incubation

Sputa mixed with milsol

Smears —None were made from groups A and B Acid fast bacilli were present in all the smears from groups C, D, and E

Cultures —All the cultures were negative for *M tuberculosis* after 10 weeks

Experiment II

Method —150 ml of milsol was placed in each of six 1-lb jam jars, and 10–15 ml of sputum known to contain large numbers of tubercle bacilli was added. More sputum was added after 1, 2, and 4 hours The jars were shaken after each addition 30 minutes after the last addition of sputum ($4\frac{1}{2}$ hours after commencement) 5 ml of scum was removed and cultured as described in experiment I 2 hours later ($6\frac{1}{2}$ hours after commencement) another 10–15 ml of sputum was added. The jars were then left overnight Next morning (23 hours after commencement) more sputum was added to the jars, and 30 minutes later 15 ml of scum was removed from each, treated as described above, and cultured This procedure was repeated 2 hours later Finally, all the jars were emptied, and swabs for culture were taken from their rims Control smears and cultures were also made from four samples of the original sputum

Results —The following results were obtained

Controls

Smears —Acid fast bacilli were present in smears from all the specimens

Cultures —All cultures were positive for *M tuberculosis* after 4 weeks' incubation.

Sputum mixed with milsol

Smears —Acid fast bacilli were present in all the smears *ultures.*—All the cultures were negative for *M tuberculosis* after 10 weeks incubation

bs from rims

ultures.—All the cultures were negative for *M tuberculosis* after 10 weeks incubation.

Conclusions

Milsol was found rapidly lethal for *M tuberculosis* and longed contact with sputum did not significantly luce its bactericidal properties for this organism

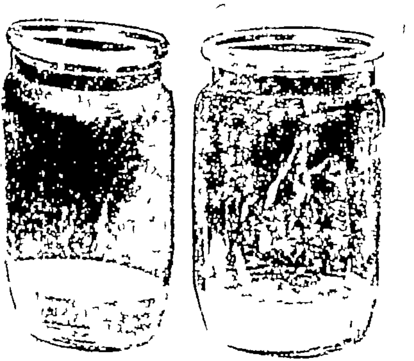
Milsol quickly dissolves sputum and these qualities gest a simple technique for the disposal of sputum in home Using two receptacles a routine may easily devised which ensures bactericidal action by milsol. e adoption of this technique should satisfy both thetic and bacteriological requirements

SPOSAL OF TUBERCULOUS SPUTUM IN THE HOME A NEW METHOD

PETER STRADLING
M.D Lond. M.R C P
NSULTANT CHEST PHYSICIAN HAMMERSMITH CHEST CLINIC
D HAMMERSMITH HOSPITAL LECTURER IN TUBERCULOSIS
POSTGRADUATE MEDICAL SCHOOL OF LONDON

THERE are at present three main methods of disposing the sputum of tuberculous patients (1) the use of a g which contains a disinfectant (e g Lysol) and must cleaned and sterilised daily (2) the use of paper ndkerchiefs which can be thrust into a paper bag by e bedside; and (3) the use of small disposable cartons patients with more copious sputum or by any patient m whom a specimen is needed. The infected handker iefs and cartons are easily destroyed by incineration. is is the cleaner and probably safer method but utum mugs are still used freely In the home when special facilities for cleaning sterilisation, or inciner ion are available, all these methods become most nsatisfactory

The Milton Deosan Research Laboratory have pro iced an antiseptic ('Milsol) which can be of con iderable value in the disposal of sputum in the home. he basis of the fluid is a modified hypochlorite solution wo fundamental claims are made for it: the sputum is mogenised, with the result that the bacilli are freed to the fluid and no tenacious particles remain and e bactericidal action is of a high order even for tubercle cilli.



(a) (b)

Two jam-jars containing equal quantities of sputum added fifteen minutes previously to (a) milsol and (b) 1:20 carbolic acid.

Personal communication with Dr R W Riddell, of the bacteriological department of Brompton Hospital satisfied me that, *under laboratory conditions* the bactericidal and homogenising actions of milsol were highly effective Formed tenacious sputum was changed in the receptacle into a relatively clear, homogeneous, and sterile fluid easy to dispose of (see figure) Although milsol was satisfactory in the laboratory, it seemed essential that a field trial should be undertaken in the patients own homes under ordinary conditions Such a trial is reported here

Method

All patients using milsol were issued with the maker s instructions as follows:

> "Place 1–3 oz. of milsol in the sputum container (a 1 lb. jam jar is very suitable) according to the amount of sputum normally produced. The fluid in the jar will be quite clear at disposal time if the amount of milsol has been adequate Add more as necessary
>
> After each expectoration rotate the container so that the milsol washes the sides, keeping them clean and free from sputum particles. At the end of 24 hours, and before disposal, leave the container one hour after the last sputum has been added.
>
> Rotate the container and empty the contents down the lavatory Wash it thoroughly in two pints of water to which half a teaspoon of milsol has been added (use a plastic spoon) Add further milsol and return to use

Further explanation was given to the patients by the health visitors as necessary

Trial

Altogether 41 separate investigations were undertaken on 25 patients producing adequate quantities of sputum These patients were provided with milsol, instructed in its use and asked not to empty the sputum pot but to keep a 24 hour specimen for collection by the health visitor In addition they provided one specimen of untreated sputum (for control) expectorated at some time during the same 24 hours as the rest of the sputum was deposited in the milsol fluid.

There was an interval of 1 or 2 hours between collection of the specimens and investigation in the laboratory which was done as follows

(1) *Control sputum.*—Each specimen was treated with 4% sodium hydroxide and centrifuged, and the deposit was washed with distilled water 1 loopful of the deposit was added to a Löwenstein-Jensen slope

(2) *Milsol.*—20 ml of the fluid was centrifuged, and a loopful of the deposit was added to a Löwenstein-Jensen slope.

(3) *Jars*—The inner surface of the top of each jar was swabbed out with a throat swab The swab was treated with 4% sulphuric acid, neutralised, and rubbed on the surface of a Löwenstein-Jensen slope.

All the cultures were incubated for 8 weeks, and the results were read in terms of the degree of growth (maximal +++)

Results

Of the 41 control samples of sputum in the trial 11 yielded no organisms. By providing 1–3 positive sputum samples each, 18 patients yielded the 30 positive results (16 +++ 10 ++ 3 + and 1 with only two colonies)

All the cultures taken from the inside of the 30 jars provided by the sputum positive cases proved negative, as also did 28 of the 30 milsol fluids investigated. There remained 2 milsol samples from which positive cultures were obtained (from a +++ sputum and a ++ sputum) Both these cultures, however provided very scanty growth, only one colony being present on one slope and six on the other Thus only seven colonies of tubercle bacilli were cultivated from a bulk of milsol fluid which contained 30 24-hour specimens of positive sputum 26 of which had yielded heavy growth when cultured directly

Discussion

Non-homogenising disinfectants are bacteriologically unsatisfactory in sputum mugs because unchanged sputum particles can contain living bacilli even though they have been in contact with the disinfecting agent for many hours Adequate cleaning and sterilisation of the sputum mug thus entail daily treatment with soda and subsequent boiling The results reported for the above described simple method, however, appear excellent, particularly when it is realised that, in the case of the 2 milsol positives obtained, the patients involved had very copious sputum and had not added additional milsol to ensure a clear residual fluid There is little doubt in my mind that these fluids also would have been negative, had the patients followed the instructions more carefully In view of this finding I will in future recommend patients to add at least 4 oz of milsol to a 1-lb jam jar (a third of its capacity) to ensure adequate homogenisation and sterilisation of the sputum

Apart from the good bacteriological results obtained, milsol also proved satisfactory æsthetically Most patients, as well as those relations who were acting as nurses in the home, were enthusiastic about this method of disposing of the sputum, the repulsive duty of disposal and cleansing of receptacles had been superseded by a simple, rapid, and safe process

Some patients objected to the smell, and one found that his asthma was aggravated when he leant over the pot to expectorate In addition there is the danger of bleaching carpets and bed-clothes if the milsol is spilt It should be remembered also that only glass or inert plastic containers can be used, because of milsol's corrosive action A 1-lb jam jar is satisfactory and easily replaceable at no cost in any home

There is no doubt whatsoever that milsol represents a great advance on the non-homogenising antiseptic fluids commonly used in sputum containers and at the same time is no more poisonous *It could with advantage* take the place of these not only in the home but also in hospitals using a sputum-mug method of disposal, since there would be less risk of infecting the nurses Milsol also appears to have advantages, particularly at home, over paper handkerchiefs which are expensive, inadequate when there is copious sputum, and need a fire during the summer

Summary

A new antiseptic fluid, 'Milsol,' has been subjected to a small clinical field trial in the homes of tuberculous patients

Milsol proved bacteriologically satisfactory and homogenised sputum, facilitating the cleansing of sputum receptacles

It was acclaimed by those involved as a simple and æsthetically acceptable procedure

This trial has thus shown that milsol has great advantages over other known methods for disposing of tuberculous sputum in the home

My thanks are due to Dr D A Mitcheson and his laboratory staff for the bacteriological work involved, Milton Antiseptic Ltd, who introduced this method and supplied the milsol, and my health visitors for their wholehearted coöperation in the distribution and collection of specimens

---

"The demand for sedatives and drugs is a reflection on our present civilisation It has been suggested that the broken home, the gangster film, the present insecurity, and the lack of religious and spiritual comfort account for our increase in crime They also account for our craving for medical panaceas for our spiritual discomforts We would cut the *drug bill if we could substitute the priest for phenobarbitone*, spiritual values for vitamins and hobbies for hormones" —'Consultant Physician' *Manchester Guardian*, Nov 23, 1953, p 5

MERCURIAL POISONING IN EARLY CHILDHOOD

H G Farquhar
B M Oxfd, M R C P, D C.H.
ASSISTANT PHYSICIAN,
ROYAL LIVERPOOL CHILDREN'S HOSPITAL

THE following two cases are published as a further warning against giving mercurial teething powders to infants

Case-records

Case 1—A boy, aged 5 months, attended hospital with *pink disease* He had received two teething powders each week for the previous month, each powder containing 52 mg. of calomel Recovery took place slowly but was complete in two months

A year later, at the age of 16 months he began to cut more teeth, and his mother gave him a further teething powder Three weeks *later this was repeated* According to his parents these were all the mercurial powders he had had a friend of the family suspected that others had been given, but this was never proved. Two days after the administration of the last powder the boy's abdomen began to swell and his urinary output to fall, and he was brought to hospital again

Examination revealed a fretful grossly œdematous child with ascites The blood pressure was 120/75 mm. Hg and the urine contained large quantities of albumin but no casts, red blood-cells, or other formed *elements* The blood-urea was 30 mg, the total plasma proteins 4 5 g., the plasma-albumin 1 2 g, and the plasma-globulin 3 3 g per 100 ml.

Course—A sample of urine taken two days after admission contained 90 µg of mercury in 100 ml Twenty three days later, when the boy was receiving no mercurials, it still contained 15 µg in 100 ml The former quantity indicates severe mercurial poisoning The child went steadily downhill and died seven weeks after admission During this time the urine remained loaded with albumin but without any gross hæmaturia The plasma albumin level remained constantly below normal and below that of the globulin, and the blood-urea remained within normal limits until eighteen days before death, when it rose to 80 mg per 100 ml The clinical picture was that of a nephrosis

Necropsy showed gross œdema of all tissues, with free fluid in the serous cavities. The kidneys were enlarged, weighing 220 g, the glomeruli were excessively cellular, and rare crescent formation had taken place The proximal tubules were normal, and the distal convoluted tubules and the collecting tubules showed some regeneration and peri-tubular fibrosis The blood vessels were normal. The final pathological diagnosis was glomerulotubular nephritis of some weeks' standing with no evidence of mercurial poisoning

Chemical analysis of the organs gave the following results

Organ	*Weight examined* (g)	*Mercurial content* (µg)
Kidneys	220	220
Liver	285	280
Intestines	120	10
Stomach	70	30
Heart	55	20
Femur	75	Trace only

The estimated total amount of mercury in the body at death seven weeks after the cessation of all mercurial administration was 5 mg, equivalent to gr $^{1}/_{10}$ of mercurous chloride

Case 2—A boy, aged 6 months, was referred to hospital because of occasional vomiting for fourteen days and almost complete refusal of food for four days He had received one-quarter of the same mercurial teething powders as case 1 (i e, about 13 mg) every night for the previous three months He had been vaguely off colour for the same time

Examination showed him to be underweight for his age—10 lb 6 oz He was remarkable for his extreme misery and perpetual restlessness He continually pulled and scratched his skin, and he caused sores on his heels by rubbing his feet together and against the bed clothes His eyes were kept half closed, as if the light were painful to them, and whenever possible he rolled into the prone position and buried his head in his pillow, the only position in which he could sleep. His skin was clammy and cold and his extremities were cyanosed but not pink. Hypotonia was marked, but tachycardia was absent ucal diagnosis of pink disease was made and a specimen e was sent for mercurial analysis before treatment . Unfortunately on the sixth night in hospital he y collapsed and died. During his short stay in hos s urine contained only a trace of albumin, without cess of cells or casts. The blood-cells were normal ne contained 404 µg of mercury per 100 ml.

opsy, delayed for twenty four hours revealed no gross in any organ, and microscopy of the kidneys showed nite changes that could not be attributed to post- n changes.

ical analysis of the liver showed 3300 µg of mercury ug and Nelson s method or 5900 µg by Simonson s l in 145 g of tissue The kidneys contained 18 500 µg cury by Laug and Nelson s method or 17 500 µg onsen s method in 45 g of tissue

Discussion

evidence that the administration of mercury to n may be incriminated in a number of pathological ions is increasing Warkany and Hubbard (1948) ered abnormal quantities of mercury in the urine of 41 children with pink disease Since this on was not shown by all the children exposed to the those workers suggested that pink disease may be ersensitivity reaction to mercury The evidence is explanation and a very full examination of the subject is contained in a later report (Warkany Iubbard 1951) The association of pink disease ercurial poisoning has been confirmed by Bivings ewis (1948), Carithers (1949) and Holzel and (1952) The last named, working in this country abnormal quantities of mercury in the urine of 94 cases of pink disease.

it severe renal disease can be caused in children ronic mercurial poisoning from calomel in teething ers has been demonstrated in 5 cases in this country, f them fatal (Wilson et al 1952) Unfortunately cropsy was allowed.

likely is calomel to cause disease that Continental ers write of calomel disease and describe the and allergic effects due to it (Fanconi et al 1947)

zel and James found that of a series of infants ding Manchester and Salford infant clinics some had received mercurial teething powders and 3 consecutive children under the age of 3 years ding the casualty department of the Royal Liver Children s Hospital 130 had received teething ers, of which 94% contained calomel 51% of the pool children receiving powders containing calomel had these one or more times each week during the d of administration

far as case 1 is concerned the evidence that the disease was due to mercurial sensitivity is purely mstantial. That mercury had been given is itted, but there is no evidence that abnormal amounts ercury were present in the body or excreted in the when the baby had pink disease That severe curial poisoning had taken place during the later is evident from the amounts of mercury found e urine and in the organs post mortem. The clinical re was one of nephrosis, but the histological picture that of glomerulonephritis. Was this an ordinary gic glomerulonephritis following a previous infection possibly aggravated by the mercury or was it an gic reaction to the mercury itself? Though the r possibility may be remote it seems unwise to lude it, particularly as other allergic reactions to rcury are known It may be relevant that glomerular ction in the dog has been shown to be severely inter ed with by mercury (Handley et al. 1949) and rpaneto (1947), using corrosive sublimate, has described ons in guineapigs very similar to those of nephritis.

In case 2 mercurial poisoning was undoubtedly present ring the course of the pink disease grossly toxic quantities of mercury being found not only in the urine but also in the organs after death.

Summary and Conclusion

Two cases of fatal calomel poisoning are described, both of which showed symptoms of pink disease, and one of which showed evidence of severe renal damage Administration of calomel to children seldom leads to gross evidence of disease but severe or fatal illness has occasionally followed it In the absence of any conclusive evidence of the beneficial effects of calomel in small children, and in view of its possible harmful effects its widespread and public sale should be condemned

I would like to thank Dr R W Brookfield for his advice on the presentation of this paper Dr R. E. Rowell and Dr T Black for the pathological examinations, Mr N Heron for the chemical analyses in case 1 and Mrs. D Dean for the analyses in case 2 and a critical examination of the techniques available, and Dr M Tun for the collection of statistics.

SIMPLE ŒSOPHAGEAL CAST

I McLean Baird
M B St And., M.R C P
SENIOR MEDICAL REGISTRAR

Harold Cohen
M.B Sheff M.R.C.P
SENIOR HOUSE OFFICER

ROYAL INFIRMARY SHEFFIELD

Simple œsophageal casts are extremely rare: only 19 cases have been reported since the condition was first described by Birsch Hirschfeld (1877) Patterson (1935) reviewed 17 cases and added 1 of his own and since then only 1 further case has been reported (Willcox 1949) Reichmann (1890) designated the condition "œsophagitis exfoliativa," and Rosenberg (1892) named it "œsophagitis dessicans superficialis. The sex distribution of this condition is equal, and the ages of the patients vary widely (from 20 to 60 years) There was recurrence of cast formation in 4 cases.

A simple œsophageal cast differs from a cast due to corrosive poisoning; the latter frequently leads to stricture formation (Kauffman 1911) while the former leaves no sequelæ. Diphtheritic œsophagitis has been known to lead to cast formation (Raw 1901) Varying ætiological factors have been mentioned as causes for simple cast formation; Patterson suggests a peculiar exfoliative tendency and cites 1 case with severe generalised eczema (Sligh 1893) In most cases the ætiology is

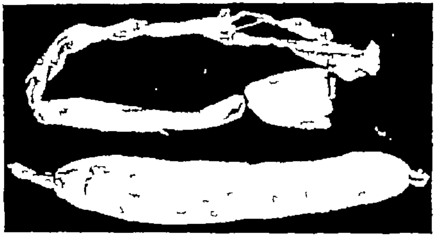

Fig. 1—Œsophageal cast.

obscure although there is often a history of earlier minor œsophageal trauma as in the case reported here

CASE-REPORT

A married woman, aged 35, attended hospital on Jan 4, 1953, complaining of a sensation as of a potato-chip sticking in her throat She experienced this first while eating her evening meal She was examined in the casualty department, and no abnormality was found in the throat or elsewhere She was asked to return for a further examination should the symptom recur A feeling of soreness persisted for a few days but she remained well for seven weeks On Feb 22 she felt a "heaviness" behind the upper sternum, shortly after a breakfast of bacon and tomatoes This was quickly followed by the vomiting of bright red blood, and of a whitish tube She felt that she was choking and replaced the tube by pushing it back into her throat and swallowing This manœuvre was temporarily successful but after fifteen to twenty minutes she vomited again and the tube became detached completely from her throat The patient now felt very ill and was alarmed because she thought "the lining of her throat had come away" The family doctor was called in, and found the patient pale, sweating, and complaining of soreness in the throat A sedative was given and the patient advised to take fluids only by mouth The cast was examined and preserved The swallowing of saliva was very painful after the tube had been vomited, and intense retrosternal discomfort was induced by the swallowing of fluid The soreness gradually diminished, and by the time she was admitted to hospital on March 4 she could eat semisolid food with only mild discomfort There was no history of swallowing alcohol or corrosives, or any other toxic substances The meal preceding the vomiting of the cast was regarded by the patient as a normal breakfast Her general health was good and she felt perfectly well between the episode of dysphagia on Jan 4 and the vomiting of the cast on Feb 22 She had had no serious illnesses and there was no relevant family history

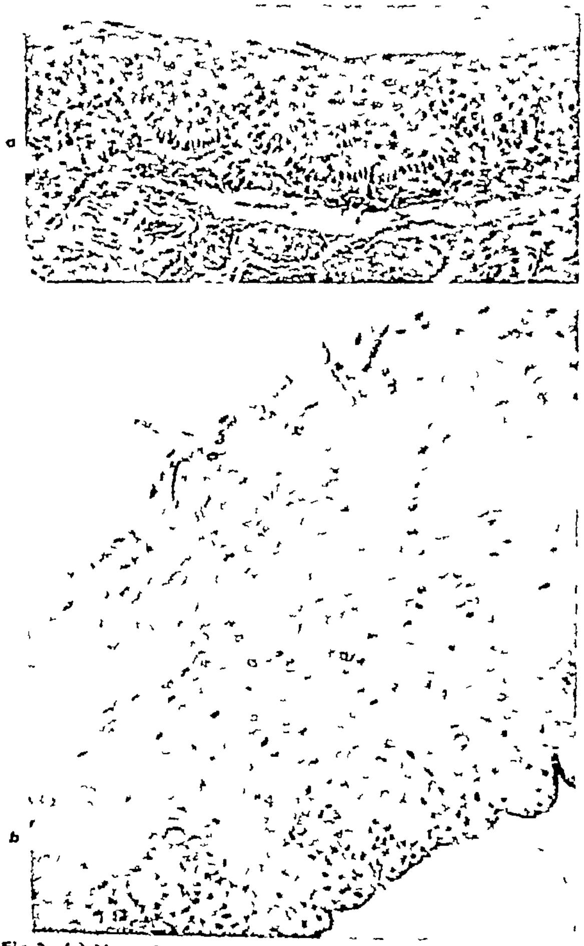

Fig 2—(a) Normal œsophageal epithelium. (b) Section of œsophageal cast (both × 132)

On admission she was pale but not anæmic, and the tongue and fauces appeared normal The blood pressure was 120/70 mm Hg, and no abnormalities were found in any system Œsophagoscopy, sixteen days after the vomiting of the cast, showed a pale atrophic mucous membrane until the œsophagoscope had been passed to 25 cm , beyond this the mucosa was hyperæmic and bled at the slightest touch A barium swallow seven days after the œsophagoscopy revealed no abnormality The blood count was normal , the erythrocyte-sedimentation rate (Wintrobe) was 33 mm in the first hour, the Wassermann reaction was negative

The cast when recovered was a thin walled complete tube so friable that it later broke into two pieces, one 17 5 cm in length the other 14 5 cm , the diameter was 2 cm. (fig 1) The wall was thin, smooth, pearly white, and translucent and showed no red capillary streaks There were no constrictions corresponding to the natural anatomical configurations of the œsophagus Microscopically, it consisted of stratified squamous epithelium, the cells having vesicular nuclei, often surrounded by distinct spaces , there was no infiltration with inflammatory cells The basal layer showed occasional rosettes of cells which probably represented the severed tips of the papillæ (fig 2) The appearances were similar to those described by Patterson and Willcox

DISCUSSION

An œsophageal cast is formed as the result of a split in the wall of the œsophagus , and since it consists entirely of epithelium, the split must occur either through the epithelium or just below the basal layer If the whole epithelium were shed, healing would be by granulation, with scarring and stricture formation , but after a cast has been exfoliated there is rapid and complete recovery Presumably therefore the split occurs through the epithelium, and leaves the œsophagus lined by a thin residual epithelial layer The œsophagoscopy findings in the present case support this view

In an attempt to demonstrate planes of separation we have tried unsuccessfully, in necropsy specimens, to split normal œsophageal epithelium It is not difficult in these specimens to tear off a thin superficial sheet of tissue, but microscopically this artificial cast is seen to consist always of epithelium with an adherent strip of corium A further attempt to split the epithelium has been made by injecting saline through a Mantoux needle as superficially as possible into the wall of a normal œsophagus removed at autopsy Sections of these preparations show that the corium is distended but the epithelium remains intact Normal epithelium is thus difficult to split, so when a cast is formed the epithelium is probably abnormal

In our case the epithelium of the cast is three times as thick as that of a normal œsophagus , microscopically it closely resembles the photomicrographs of the specimens described by Patterson (1935) and Willcox (1949) To investigate whether this thickening was an artefact, a sheet of epithelium and corium stripped from a necropsy specimen was treated in water and spirit, in the same way as the cast This did not swell, and its thickness was unchanged , it merely showed changes due to shrinkage of cells The abnormal appearance of the cast is thus unlikely to be an artefact, and it may be due to epithelial proliferation We have been unable to find any cause for this

A cast may be shed in two ways as a whole, when it is vomited as a coiled intact tube, or as an invaginated tube which is stripped off the wall as the free end passes up the œsophagus, like a sleeve being turned inside out In the second case a section of the cast would show the superficial layer of the epithelium on the outside of the tube Our specimen does not show this, nor do the specimens of Patterson and Willcox The likely sequence of events in these cases was therefore a general loosening of epithelium with exfoliation of a coiled intact tube, The only exception, so far has been recorded by Sclavunos (1893) who noted invagination of a cast, but in this instance the patient vomited a cast shortly after drinking a quantity of industrial spirit, so the case cannot be regarded as typical.

We suggest that the cast is formed in the following manner:

1. Epithelial hyperplasia results from an unknown cause
2. A small split is produced, possibly by trauma, in the abnormal œsophageal epithelium
3. The act of deglutition causes a rise in intra-œsophageal pressure and may gradually cause a progressive dissecting split.
4. New epithelium is growing from the basal layer as the slow dissection proceeds.
5. The final separation of the cast is induced by vomiting

We are indebted to Dr H. P Brody for permission to report this case and for his helpful advice and to the photographic and pathological departments Royal Infirmary Sheffield, for their coöperation

ISSECTING ANEURYSM OF THE AORTA

RECOVERY AFTER TREATMENT WITH HEXAMETHONIUM

D A PYKE
M.B Camb., M.R C.P
NIOR MEDICAL REGISTRAR, RADCLIFFE INFIRMARY OXFORD

In the case reported here a patient with dissecting eurysm of the aorta was treated with hexamethonium omide and recovered.

CASE REPORT

A housewife aged 60 who had previously been in good alth, was stricken one morning by a sudden extremely vere pain in the upper abdomen and passing through to e back between the shoulder blades. Almost immediately terwards the pain spread to the right leg which felt cold d useless." The patient said that her husband, feeling e legs, noticed that the right was very cold. There was so some "cramp in the left leg The pain in the trunk sisted throughout the day and she vomited several times. e pain, coldness, and uselessness of the right leg, wever gradually lessened.

On admission to hospital twelve hours later she was still great pain. Her blood pressure was 230/120 mm. Hg in ch arm, and heart-rate 80 regular The apex beat was lf an inch outside the nipple line and at the apex there s a harsh systolic murmur which was also audible along e left border of the sternum. The radial pulses were equal d normal. The right femoral pulse could not be felt e left was palpable though weak. The popliteal dorsalis dis, and posterior tibial pulses were impalpable in both gs. The optic fundi showed narrowing and irregularity of e retinal arteries. The urine sp gr 1 018 contained a oderate amount of albumin but was otherwise normal. The rest of the examination was negative.

Mr. M. H. Hall, the surgical registrar who first saw the tient, made a diagnosis of dissecting aneurysm of the aorta, d she was transferred to the medical side

Investigations

Chest radiography showed an enlarged left ventricle and oss unfolding of the aorta. Electrocardiography showed left ventricular hypertrophy Erythrocyte-sedimentation rat (E.S.R.) 13 mm in one hour Hb 98%; white-cell coun 14 000 per c mm.; blood urea 67 mg per 100 ml. urinar urea 3 4 g per 100 ml Straight radiography of the abdome showed no gall stones. Serum and urinary amylase level were normal.

Treatment and Progress

Treatment with hexamethonium was begun immediatel (within an hour of admission and thirteen hours from th onset) Hexamethonium bromide 25 mg subcutaneously reduced the blood pressure to 135/80 mm. Hg By the nex day the pain had lessened and a thrill was felt over th right femoral artery The power and temperature in bot limbs were equal The blood pressure was maintained a 100–170 mm. Hg systolic and 70–100 mm. Hg diastolic b injections of hexamethonium given as indicated by the hourl blood pressure chart usually every four hours. The patien was propped up on pillows and the head of the bed was raise on blocks. With increasing tolerance the successive dose of hexamethonium were gradually increased over eigh days to 100 mg but thereafter no further increase wa necessary

Some pain in the back persisted for several days. It wa noticed that the patient complained of pain chiefly whe her blood pressure was highest and another injection wa due Injection of the hexamethonium then appeared t relieve it When unknown to the patient saline solutio was substituted for hexamethonium injections did not brin relief When hexamethonium was renewed and the blood pressure fell pain was again relieved After two weeks the pain disappeared and did not recur even when hexamethonium was temporarily discontinued and the blood pressure was allowed to rise to 220/130 mm. Hg

At this time the patient developed a new murmur—a loud continuous machinery like sound, best heard down the left border of the sternum but audible all over the præcordium and occupying the whole of the cardiac cycle with an accentuation at the beginning of systole

The E.S.R. rose to 50 mm. in one hour two days after admission The blood urea level gradually fell to 30 mg per 100 ml. Urinary output remained satisfactory and after the first day there was never more than a trace of albumin in the urine. She developed cystitis, which she said she had often had in the past *Escherichia coli* was cultured from the urine and treatment with sulphonamide was begun. The urinary infection recurred when chemotherapy was stopped but was suppressed by its resumption. Throughout her stay in hospital she had slight fever her temperature being 98°–100°F The E.S.R. remained high, and she had a persistent slight leucocytosis.

Outcome

After five weeks she was allowed up and after ten weeks she returned home The physical signs on discharge had not changed. The patient had learnt to give herself hexamethonium injections; but, with clinical recovery the interval between doses had been increased to eight hours, and with the increasing assumption of the erect posture the dose had been reduced to 50 mg On discharge the patient had no complaints and said that she felt perfectly well. When seen as an outpatient seven months later she reported that she could do light housework and had no complaints. The physical signs were unaltered.

DISCUSSION

Dissecting aneurysm of the aorta is a not uncommon post-mortem finding being found in 0 2–1 5% of cases (Lawson 1952 Mote and Carr 1942) but it is less frequently diagnosed during life, and recovery is uncommon. That some patients have recovered from a dissecting aneurysm is shown by the occasional necropsy finding of a healed dissection or of a double aorta.

Most patients with dissecting aneurysm have a high blood pressure, and this is often maintained after the onset of the dissection (Baer and Goldburgh 1948, David et al. 1947)

Figures for the time of survival after dissection suggest that more than half the patients live for twenty four hours or longer, and about 10% live for some months or years (Lawson 1952, Levinson et al 1950) In a first attack death is nearly always due to external rupture of the aneurysm (David et al 1947), but of Shennan's (1934) 79 cases of old "healed" dissecting aneurysm death was due to recurrent or second dissection with hæmorrhage in only 28 Shennan concluded

> "The main factor determining the length of survival of all cases of dissecting aneurysm subsequent to the occurrence of the primary tear is the varying period during which the blood pressure is maintained at the height at which the primary rupture has been produced"

In the present case treatment with hexamethonium was started as soon as a dissecting aneurysm had been diagnosed, and the blood-pressure was continuously maintained at relatively low levels There were no apparent ill effects from this It is impossible to say how much, if at all, hexamethonium contributed to the patient's recovery, but this treatment seems worth using in future in those patients with dissecting aneurysm of the aorta whose blood-pressures are high and who survive long enough to reach hospital

SUMMARY

A case of dissecting aneurysm of the aorta wi hypertension is described in which hexamethoniu bromide was administered and the patient recovered.

Since death in a first attack is nearly always due external rupture, it may be worth trying hexamethoniu treatment in cases where the patient is hypertensi (as he frequently is) and survives long enough to rea hospital

I am grateful to Dr A M Cooke for permission to publi this case and for his advice

Preliminary Communication

ISOLATION OF A CRYSTALLINE PROTEIN FROM HIGHLY PURIFIED DIPHTHERIA TOXIN

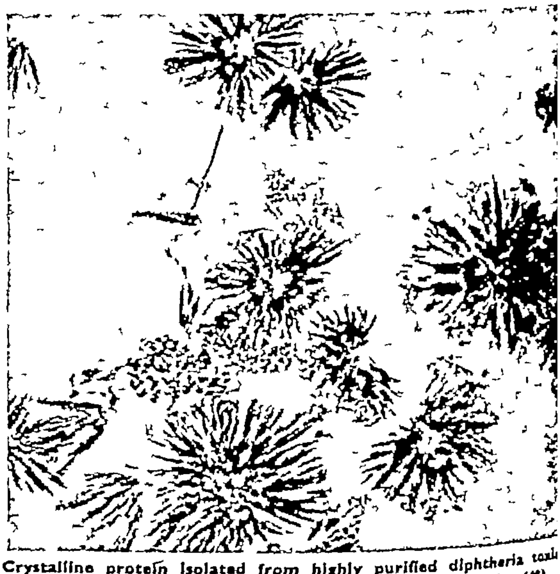
A RECENT annotation[1] in this journal reviewed progress towards the isolation of pure antitoxin The purification of diphtheria toxin appeared to have been achieved as a result of the work of Eaton[2] and Pappenheimer[3] but later work by Pope, Stevens, Caspary, and Fenton[4] suggested that the highly purified toxin still contained a large number of antigens Results supporting this conclusion were also obtained by Lepow and Pillemer[5] In recent (unpublished) work we have been able to show by electrophoretic methods that it is possible to separate these other antigens and to obtain a product which gives a single line in the diffusion test described by Pope et al[4] Unfortunately the amounts of material obtained in this way are small and this has hampered our work.

Recently we have isolated a crystalline protein from diphtheria toxin after its preliminary purification by a new method (Pope and Stevens, unpublished data) A single crystallisation yields material which shows multiple diffusion lines, but the number of antigens present has been reduced After three crystallisations a product was obtained which gave a single diffusion line in the diffusion test as usually carried out, but showed slight traces of contamination on a more prolonged test

Contamination of the crystals with amorphous material has been a big difficulty, but the thrice crystallised product appeared to be free from amorphous material Whenever amorphous material has been present on microscopic examination, multiple lines due to the presence of other antigens have always appeared

Examination of the crystalline material by in-vivo and in-vitro methods has shown a very close agreement between the values per ml calculated from these tests Preliminary results indicate that this crystalline material has a purity, in terms of *Lf*/mg nitrogen, about 50% greater than the value deduced by Pappenheimer and Robinson[6] from a study of the toxin antitoxin flocc precipitates, or the value obtained by Pappenheime on isolated toxin

While it is tempting to consider that this crystalli material is the specific toxin produced by *Corynebacteriu* *diphtheriæ*, certain anomalous results with differe antitoxins suggest that it would be unwise to consid this as more than another step towards the isolation of th specific toxin



Crystalline protein isolated from highly purified diphtheria toxi First crystallisation showing some amorphous material (× 440).

The accompanying photograph shows once crystallis material, together with associated amorphous materi obtained from a toxin having an initial purity of th order of 2600 *Lf*/mg nitrogen

Full details of the methods used for initial purificatio of the toxin and its subsequent crystallisation will b published elsewhere

ROYAL SOCIETY OF MEDICINE

Rest or Activity?

On Nov 24 the section of medicine met, under the chairmanship of Sir HENRY COHEN president of the section to discuss the Use and Abuse of Rest as a Therapeutic Measure.

Dr G E BEAUMONT declared himself a firm believer in the value of rest. Tranquillity was necessary for cure, and bed meant a mind dulled and free from thought A patient who had been in bed for only a few days often grumbled a long stay patient was silent, because his mind was at rest. The temperatures of tuberculous patients often rose after they had been disturbed by visitors. Rest was a well known ingredient of the treatment of poliomyelitis and of pulmonary tuberculosis, and he was not sure that surgeons did right in insisting on exercises to promote lung expansion and prevent deformity immediately after thoracoplasty More lung was always diseased than was apparent from X ray examination, and quiescent foci might be activated by such therapeutic gymnastics and account for some of the present failures of cure Sciatica used to be treated with active physiotherapy until the prolapsed intervertebral disc was recognised and rest came into its own Subdeltoid bursitis was sometimes treated with movement to prevent adhesions forming," but in Dr Beaumont's view rest and deep X ray therapy was the only correct treatment As for rheumatoid arthritis, the essential was up to eighteen months in bed, with splints applied to the limbs. Moreover Dr Beaumont observed, exercise and worry were said to lead to obesity, so the way to slim was to go to bed.

On the other hand Prof W MELVILLE ARNOTT thought that rest in bed was very far from being a panacea, it was more like a drug of addiction? with some definite indications but toxic in overdoses and even fatal on occasion To put to bed was far too often the physician's automatic reaction when presented with illness. An experimental study was cited in which healthy young adults were immobilised for six weeks During this period their nitrogen balance was negative by 54 g they lost anything from 9 to 24 g of calcium, and this, with a high phosphate excretion predisposed to urinary calculi. Blood volume decreased and vasomotor control weakened, so that fainting was more common in the erect posture. It took these people six weeks to recover to normal. In old patients, it was already well known that a long stay in bed led to skeletal changes urinary calculi, muscular contractures, weakening and stretching of ligaments, bed sores, anorexia and constipation and a urinary incontinence which would often abate if the patient were only allowed up again Bed rest in many diseases was anatomically physiologically and psychologically indefensible; and 18th century physicians, such as Withering Heberden, and Stokes, did not advocate it. It was Hilton's mid 19th-century classic *Rest and Pain* which, rightly pouring scorn on the treatments of the time, had exalted rest above all. But things had now gone too far the other way especially when hospital care had displaced home care for patients in British hospitals were expected to stay in bed and the nursing was based on this. In Continental clinics and tropical hospitals the patients were allowed up much more, without detriment.

Professor Arnott pointed out that rest had many meanings one was absence from work. There was no conclusive evidence that hard work ever caused illness: rather the reverse. The industrial 40 hour week was an economic and political concept, not a medical one But a diagnosis of overwork hid the doctor's ignorance of ætiology and pleased the patient by depic him as a martyr before his family and friends physician had a duty to prescribe absence from w very carefully not merely in the patient's own inte but for the economic health of the country

Prof C A WELLS said he had found Hilton's book q unreadable It was irrelevant to modern surgery, wl set out to modify nature profoundly Sympathecto for example, was used to relieve the pain of an pectoris and permit a patient greater activity how t could previous pain have been a true indication for re The resting of a part was still useful in the treatmen bone and joint tuberculosis, but this did not m immobilising the whole patient; indeed, in ort pædics, muscular activity inside a plaster was axioma At Leysin, Rollier was going even further and treat *spinal* caries without plaster at all the children me lay face down in the sun and encouraged their erect spinæ muscles to develop and steady the disea vertebræ Professor Wells advocated the same techn for the prevention of prolapse of an intervertebral d In a different field a patient with severe bedsores l been saved by being turned from side to side hou day and night for rest would have been fatal

After every surgical operation, deep venous thromb was one of the risks of resting in bed—a risk grea increased if Fowler's position were still used In Profes Wells's wards every patient did a daily ten minutes leg and deep breathing exercises starting on the v day of operation, and everyone had to start getting of bed within forty-eight hours. In Madrid he l seen a partial gastrectomy performed under lo analgesia on a man who at the end got up, put on shirt, and walked back to the ward where he v forbidden to get into bed. Early ambulation was new thing Professor Wells read part of an account an ovariotomy performed in 1809 without anæsthe or asepsis, where the surgeon found the patient up a making her own bed on the fourth postoperative d Finally as another example of a new technique maki nonsense of old ideas, he instanced hibernation Bef anæsthesia began the patient was given chlorpromaz hydrochloride which inhibited the temperature cent of his brain and allowed his body to be cooled to rectal temperature of 30 C for the period of the operati without harm to brain or kidney Less anæsthetic a less oxygen were needed during the operation and all t manifestations of 'shock' were diminished Th temporary unphysiological resting of the patien tissues earned quicker recovery later with amnesia f the whole treatment.

Group Captain C J S O'MALLEY as an authori on rehabilitation, took a middle line, and quoted t R.A.F rehabilitation couplet Intermittent rest an work makes a strong and healthy erk ' He instanc the treatment of acute poliomyelitis, where he agre with Seddon that a policy of graduated exercises ga better results than either immobilisation or exerci to fatigue. He had seen improvement as late as thr years after infection when the patient took his exercis with the will to get better The problem was to kno how long to rest and when to start activity Formerl after meniscectomy for internal derangement of th knee a patient was still not back at work after twel weeks. In the R.A.F such cases went to a rehabilitati centre two weeks after operation and were back at wor in six to eight weeks. Now at Garston Manor case arrived three to five days after operation and the were back at work within four weeks. A similar speed u in recovery had taken place with herniotomies th was achieved by courses of exercises, morning and afte noon divided into half hourly periods each of whic ended with ten minutes rest and by games and wor therapy to encourage unconscious movements. Asthmati and bronchitis could be greatly helped by these courses, and they were also valuable for patients with neurosis During the war, Group-Captain O'Malley had treated orthopædic and psychiatric patients together—in the proportion of four to one In the rehabilitation centre patients got away from the hospital atmosphere of disability Such centres were cheaper to run than hospitals his own cost £7 7s 6d per occupied bed per week, whereas, on the same basis, a hospital was two to four times as expensive It was a pity that convalescent homes did not recognise these methods of rehabilitation He was convinced that rest was an overworked treatment, and he cited recent observations that in osteo arthritis of the hip it was daily use which preserved the articular cartilage He thought it significant that opposition of finger and thumb was one of the last movements to go in rheumatoid arthritis—because it was in daily use

During the discussion, Dr F H STEVENS asked for medical research into the gross osteoporosis which takes place when prolonged rest is inevitable, and Dr J W TODD wanted the Medical Research Council to undertake controlled clinical trials of rest therapy The PRESIDENT pointed out that there was some semantic confusion over the meaning of rest, and that it was unwise to make wide generalisations The treatment of coronary infarction or peptic ulcer, for instance, was bound to vary according to the extent of the lesion, the nature of the patient, and so on, and universal legislation was impossible

Reviews of Books

Basic Pathology and Morbid Histology

D B CATER, M A, M D Camb, F R C S, University demonstrator in pathology, University of Cambridge Bristol John Wright 1953 Pp 320 42s

Dr Cater's commendable aim has been to bridge the gap between physiology and pathology for the student, and to help him to understand his earliest lessons in pathology at a time when his knowledge of clinical medicine is necessarily scanty He strives to "graft on to the student's knowledge of physiology sufficient clinical information to make pathology live." By producing an easily read and graphic account of the basic pathological processes, with interesting historical references, and by making effective use of analogies between disease and warfare, he has succeeded well in his purpose But though this volume deals with basic pathology it is more than elementary the student, when he has assimilated its contents, will be equipped with up-to-date knowledge of many of the engaging problems of pathology, as well as with the essential established facts Camera-lucida drawings, several of which are in colour, are used abundantly and with effect · being admirably clear they are to be preferred to photomicrographs in a book of this kind The author and his wife evidently spent a great deal of time on their careful preparation

Pituitary Chromophobe Adenomas

Neurology Metabolism Therapy JOHN I NURNBERGER, M.D, research associate, Institute of Living, Yale University School of Medicine, SAUL R KOREY, M.D, associate professor of neurology, School of Medicine, Western Reserve University New York and London Springer 1953 Pp 282 £2 15s

THE experiences and even the fate of a patient with a chromophobe adenoma of the pituitary may differ greatly according to whether chance puts him into the hands of a general physician, a neurologist, or a "metabolician" Consultation between specialists is not always as helpful as might be hoped, because they may not speak the same language, the neurologist, for instance may not always be familiar with the biochemical terms which describe the metabolic disorders of patients with pituitary tumours Yet the patient must surely benefit if a broad view can be taken of his illness In this book two neurologists who [illegible] equipped to discuss pathological and biochemical problems have set out to "correlate information from several medical disciplines in order to portray the syndrome of chromophobe adenoma of the pituitary in its setting of pathologically modified function"

They analyse the records of 117 patients with this condition who were admitted to the Neurological Institute of New York or to the Medical Service at the Presbyterian Hospital between 1929 and 1948, and who were investigated from the neurological and metabolic standpoints. They provide a fairly comprehensive review of their subject with more than 500 references The book is long for its purpose, and the style suffers from the Germanic defects of American medical writings Fortunately, the layout makes up for such defects and the essence of the material is available in summaries which provide frequent resting-points

The fragmentation of medicine into specialties is creating a problem for our schools and teachers of medicine Not only neurologists and endocrinologists, but also the diminishing band of general physicians must welcome a book like this, which brings together two separate disciplines

Classics in Clinical Dermatology

WALTER B SHELLEY, M.D, PH.D, chief, clinic of dermatology, University of Pennsylvania Hospital, JOHN T CRISSEY, M.D, instructor, dermatology and syphilology, University of Pennsylvania Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications. 1953 Pp 467 75s 6d

THESE authors have brought together the original versions or careful English translations of 143 classical descriptions of skin diseases, by 95 writers The diseases depicted vary from the commonplace to the very rare Some accounts are individual case-reports, while others are the results of the prolonged study of many patients.

The writings are arranged chronologically, and contributions vary in length from 1 to 15 pages, von Hebra and Brocq being allotted the largest space Robert Willan (1757-1812) has pride of place as the father of modern dermatology, whose classification, based on morphology, reads almost as well today as it did when it was written his pupil Bateman (1728-1821) produced the first atlas of dermatology Among the other great names of dermatology included are Alibert Cazenave, Bazin, von Hebra, Erasmus Wilson and Tilbury Fox, Jonathan Hutchinson and Radcliffe Crocker, Pringle, Unna, Besnier—with extracts from their most important contributions Excellent reproductions of original illustrations to the articles are scattered through the clear and pleasingly displayed text

This delightful book will please all interested in the history of medicine and in the eponymous figures of dermatology

---

Parsons' Diseases of the Eye (12th ed. London J & A. Churchill 1953 Pp 606 42s)—The task of revising this favourite text for its twelfth appearance has been committed to Sir Stewart Duke Elder In the preface Sir John Herbert Parsons joins him in saying how thorough, in view of modern advances, this revision has had to be indeed, the whole text has been reset Fortunately the anatomy of the eye has remained much the same, though the physiology has displayed some of its well known restlessness Our knowledge of the ætiology and pathology of ocular diseases has advanced very fast, and, though rare diseases continue to be refused admittance, room has had to be made for such conditions as toxoplasmosis and retrolental fibroplasia which have established their importance in ocular pathology But, as every preface to a textbook on disease nowadays exclaims, the greatest changes have been in therapeutics, and in the field of ophthalmic surgery there is also much to be said about new anæsthetics The result of these upheavals is a virtually new 'Parsons" not only up to date and better illustrated, but—mirabile dictu—slimmer

Textbook of Bacteriology (7th ed London Heinemann Medical Books 1953 Pp 492 20s)—Dr R W Fairbrother's popular book is back again in a new edition, a little (but not much) stouter as age advances With revision some parts have been reduced in size, and in particular, the sections dealing with bacterial metabolism, chemotherapy, and the viruses have been brought up to date

THE LANCET

LONDON SATURDAY DEC 5 1953

More Beds?

THE last five years have seen many improvements in our hospitals Wards that were grossly over crowded have had their beds reduced to manageable numbers, nursing arrangements have been modernised, and a great deal has been done to brighten up the appearance not only of wards but also of corridors and special departments At the same time there has been much skilful and relatively inexpensive reconstruction of hospital buildings to provide better quarters for outpatients, for special departments, and for resident staff

When the hospitals were taken over by the National Health Service, between 10% and 15% of their total complement of beds were no longer in use—chiefly because of the war and its consequences. But this original complement included much unsatisfactory and overcrowded accommodation, and the time has come when these pre-war figures should be forgotten and the development of the hospital services should be considered only in terms of staffed beds In the Oxford region for example, we find that better spacing, better sanitary arrangements, and the abandonment of unsuitable premises have meant a loss of 116 beds belonging to the former complement, but despite this loss the management committees have 440 more beds at their disposal.[1] In England and Wales in 1952 463,255 N.H.S hospital beds were available for patients—an increase of some 20 000 since 1949[2] This increase has been obtained almost entirely by reopening closed wards and by using beds formerly kept vacant for infectious diseases and most of the extra beds have been allocated to the chronic sick and to specialties such as gynæcology ear, nose, and throat surgery, traumatic and orthopædic surgery and chest diseases. Perhaps more important however, than the increase of staffed beds has been the increase in the turnover of patients. In England and Wales the number of discharges per bed for general medicine rose from 11 6 in 1950 to 13 1 in 1952, and similar increases took place in other specialties Regionally the biggest increase has been that achieved by the Newcastle board, which between 1950 and 1952 improved its turnover by 16 2%[2] The improved supply has liberated an increased demand, and the pressure on hospital beds remains very great but it nevertheless looks as though the problem of hospital accommodation can be solved within a reasonable time and without astronomical expenditure The present situation is well set out by Dr F N MARSHALL, S A M.O of the Manchester Regional Hospital Board[3]

> Once again the picture presented by the returns for the year 1952 is encouraging Although the amount allowed to the Board for capital projects is barely sufficient to keep existing buildings in a proper state of repair and certainly inadequate to allow large scale building operations to be undertaken it is gradually becoming evident that, except for mental and mental deficiency purposes not many more beds are required to enable an adequate service to be given. That is not to say of course, that the quality of the hospitals and beds is satisfactory or that in certain areas there is not a definite shortage of first-class beds. Nor does it imply that hospital management could not be facilitated or that great savings could not be made in maintenance costs if some of the smaller buildings could be replaced by extensions to central or base hospitals. The returns do show however that following the redistribution of the specialist staff, the tightening up of the management consequent upon the grouping of hospitals and the abolition of outmoded rivalries, the provision of better equipment, operating theatres, laboratories, X ray departments physiotherapy and out-patient facilities, etc., the turnover in existing in patient beds has been much improved. In 1950, for instance, the number of in patients discharged from or died in the Board s hospitals was 203,414 In the same hospitals the corresponding number for 1952 was 280,593—an increase of over 10 per cent. In the same period new out-patients increased from 460 501 to 490 828 Further improvements are still possible, provided adequate nursing domestic and medical staff can be obtained but it is becoming increasingly obvious that there is a limit to the number of persons the country can spare for hospital duties and, to make the best use of the personnel available, capital investment will be necessary to concentrate their efforts and to avoid dissipation of their energies. This redistribution and building up of the specialist services is undoubtedly the most valuable service the Board has yet performed in the interests of the community it serves.'

This is, we fancy, the first post war occasion when anyone has publicly stated that there are nearly enough medical beds in any region It has however, been well recognised that the pressure on children's *beds has been much reduced and that many pædiatric* units are not always filled.

For mental hospitals and mental-defective colonies the position is far less satisfactory as was emphasised in last month's debate in the House of Commons.[4] In mental hospitals gross overcrowding still exists and it is officially estimated that mental hospitals and institutions contain 14 7% more patients than they properly have room for This overcrowding is of course worse in some of them than in others, and what it can mean in actual physical conditions was vividly brought out in the debate by Miss ALICE BACON Commenting on one mental hospital in the Midlands she said

> The wards have to be seen to be believed I saw a ward, about the size of a normal hospital ward which contained 112 beds for female patients There was not sufficient room for the patients to undress inside the ward. They had to undress in another room which, in the daytime was used as a recreation room I was curious to know how the 112 female patients managed to find their own clothes in the morning, when they were left on the floor of the recreation room at night. I was told that the female patients had their names stitched inside their corsets. Their clothes were then rolled up inside their

corsets and put on the floor at night, in 112 bundles, and the patients had to be filed into the wards where they slept and filed out again in the morning to dress "

The position of institutions for mental defectives is if anything even worse, and the waiting-lists rose from 5316 in 1949 to 9300 in 1952 The worse the living conditions become, the harder it is to retain staff, and an acceleration of the present programme for improving these conditions is desperately needed Present plans provide only for 3000 additional beds for mental defectives and about 1500 further beds in mental hospitals within the next five years

What has so far been done has been done with relatively little capital expenditure One of the lessons we have learnt is that very often an old hospital ward can be modernised at a small fraction of the cost of building a new one—as witness the new professorial unit of Maryfield Hospital, Dundee In the five years under the N H S , £35 million has been allocated to capital works[2]—mainly war-damage repairs, minor reconstructions, and major items of repair and replacement—and this may be roughly compared with the amount spent on new schools, which was £96 million in 1948–52[5] Although the picture for general hospitals is on the whole encouraging, perhaps twice the sum so far provided for capital expenditure will be needed over the next five years to complete the process of modernising old buildings There is also urgent need of a limited number of major hospital schemes to equate hospital beds with local increases in population, for virtually no hospital provision has yet been made for new towns Furthermore, the time is ripe for the rebuilding, and in some cases the re-siting, of several of the teaching hospitals So far, the teaching centres have been able to do little more than stand still, while the hospital services elsewhere have been improved The needs of medical science, as well as the reputation of British medicine overseas, make it increasingly necessary that our teaching centres should be able to hold their own architecturally with hospitals elsewhere in the world

Peripheral Embolism

A QUARTER of a century ago, surgeons boldly took up the challenge of peripheral arterial embolism, with its dramatic onset and often disastrous consequences embolectomy seemed the only means of saving limb and often life **SSABANEJEFF**[6] is credited with the first attempt at this operation in 1895, and **LABEY**[7] with the first successful operation in 1911, this was at a time when the sequelæ of chronic peripheral arterial disease, except for aneurysms, were thought to be beyond the scope of the surgeon, who had the humble rôle of amputationist after gangrene had supervened During the past twenty-five years, thanks largely to the vision and pertinacity of **LERICHE**, surgery has come to play an increasingly important part in the treatment of chronic ischæmia of the limbs, with operations to interrupt the sympathetic pathway, and to restore the blood-flow through obstructed arteries by " disobliteration " or grafting Rather surprisingly this period of great expansion and technical progress in vascular surgery has coincided with an increasing reluctance to resort to operative removal of arterial emboli Brilliant results from operation have been offset by many disappointments, owing to precarious cardiac condition of the patients, multiple or recurrent emboli, and, most often, too tardy intervention Clearly the retreat from the policy of a generation ago has corresponded with the introduction of anticoagulants. Armed with these drugs, physicians, who see most of the cases of embolism, have observed more attentively the natural course of events, and have been impressed by the survival of many limbs—and patients—without surgical treatment Prominent among the factors influencing the outcome in untreated cases is the site of the embolus It has long been recognised that in the upper limb gangrene rarely ensues and recovery is usually unattended by appreciable functional impairment In the lower limb, emboli lodging below the knee may likewise cause only transient pain and weakness On the other hand *calamitous consequences usually result from* emboli lodging at the bifurcation of the aorta or in the iliac arteries, and often from femoral or popliteal emboli In the great majority of cases embolism arises from rheumatic heart disease with auricular fibrillation, or from arteriosclerosis with coronary thrombosis and cardiac infarction , and the prognosis depends largely on the cause **ANDRUS**,[8] describing a series of 57 cases treated without operation, says

> " In general, it may be said that the patient with arteriosclerotic heart disease has a much poorer prognosis because of the severity of the cardiac lesion itself and the lack of cardiac reserve, in contrast to the patient with uncomplicated rheumatic heart disease, who, despite the presence of fibrillation and the development of a clot in an auricular appendage, often has a fairly good cardiac status In addition, the peripheral arterial system in the rheumatic patient is ordinarily normal because of his lower age and the fact that the disease is usually limited to the heart itself In the elderly patient with arteriosclerotic heart disease, however, the process which has affected the myocardial vessels usually represents only a part of a widespread disease and has brought about a serious narrowing of the peripheral vessels as well "

Initially spasm of the arterial wall occurs at the site of the embolus and to a varying extent distally, and this may itself impede the development of collateral circulation and endanger the limb After a few hours secondary thrombosis, spreading mainly distally from the embolus, further reduces the blood supply by blocking the mouths of available collateral arteries Thus the promptness with which operation is done is most important In cases which are not operated on, the course is largely unpredictable, for proneness to vascular spasm and to thrombosis varies widely between different people and in the same person according to his health and physiological activity Spasm can now be combated with procaine and other antispasmodics administered by paravertebral sympathetic infiltration or by intra-arterial injection, and thrombosis by anticoagulants, the most important of which is heparin Yet **ANDRUS**,[8] reviewing cases treated with anticoagulants and antispasmodics without embolectomy, states

> " it must be admitted that almost all patients who had suffered embolism of the leg vessels and survived without gangrene had some impairment of function or

limb Their disability varied from mild weakness signs of circulatory deficiency such as intermittent dication to severe weakness and neurologic disturb es such as numbness, tingling or spontaneous pain the involved extremity In the elderly arteriosclerotic ent this, while not ideal, presented a tolerable dition, but in a number of younger patients it con uted a serious handicap to an active life.

DRUS concludes that in patients seen less than elve hours after the onset of femoral or popliteal bolism secondary to rheumatic heart-disease with t cardiac decompensation, the addition of emboleo ny to conservative measures would improve the rly results and avert much of the late disability holds that embolectomy is imperative for all tients with saddle emboli of the aortic bifurcation, emboli in the iliac arteries, who will tolerate the eration. At present arterial embolism should *ways be regarded as a potential surgical emergency* d the patient should immediately be placed under nditions where prompt operation is possible RTY[6] writes thus

> “Decision is the keynote of success in the management peripheral emboli Preparations must be made for eration at the earliest possible moment. Temporizing easures should only be considered when the cardiac ate of the patient absolutely contraindicates operation a rare contingency *when it is remembered that most* bolectomies can be performed under local anaesthesia. the interval between the onset of symptoms and eration all possible measures should be employed to omote the collateral circulation and to delay throm sis. Occasionally such an improvement in the circula on of the limb will follow sympathetic block and dministration of heparin that postponement of operation ill be justified Only recovery of such degree that the eripheral pulses re-appear can justify persistence with n-operative measures beyond 8 or 10 hours After is interval embolectomy is menaced by rapidly iminishing chances of success, but with the use of eparin and sympathetic block the period for possible ccesses may come to be appreciably extended. When xploration reveals adherence of the embolus, secondary hrombosis or a damaged arterial lining arteriectomy nd perhaps disobliterative endarteriectomy offers the est hopes of conserving limb function and life

Further improvement of medical or surgical treatment may finally *bring embolism decisively within* the orbit either of the physician or of the surgeon or perhaps a more discriminating appreciation of the needs of each patient may bring both together with better results than either can obtain alone Meanwhile, more data should be collected on the long term functional results in limbs which have urvived an embolus under conservative and under perative treatment

Milk and Water

THERE has long been a tenet that a mother who has insufficient milk for her baby should drink as much as she can. It is a natural enough belief, and there has seemed to be more to it than mere wishful thinking because of the misleading facts of the draught reflex. When a baby goes to the breast there is normally a centripetal nervous stimulus which evokes a humoral discharge from the posterior pituitary gland. This secretion, carried round the body, causes contraction of the myo-epithelial cells round the alveoli of the mammary gland The pressure within the breast rises sufficiently to give the mother a sudden tense feeling in the breasts and milk often runs from the nipples Many people who have to deal with lactation—farmers doctors nurses, and mothers—have difficulty in believing that this is not the time when the milk is made in fact, it is made at an almost constant rate day and night The draught reflex is the essential part of the mechanism of milk withdrawal This reflex, evoked primarily by the baby taking the breast, can also be set off, when the breasts are full, by the mother thinking about her baby or performing actions associated with feeding time Many women who make a habit of drinking water immediately before a feed experience the draught reflex on taking any cold drink This is the misleading fact, for as the mother puts the glass down she feels the “milk coming into her breasts” and may see it flowing out, so she naturally concludes that she has been making some extra milk Successful lactation requires an effective and appropriately timed draught reflex and research has shown that the reflex should not be falsely evoked In the cow the corresponding reflex, when elicited, must be followed by milking at exactly the right time or the milk yield is reduced, and it cannot be so effectively evoked a second time In the human the draught is more vigorous when the *child takes the first breast than when he takes the* second, and presumably it cannot be constantly repeated A draught reflex evoked by a cold drink may therefore expend the vigour that should have been saved for the baby when he takes the first side

The false evoking of the draught reflex, which is probably the basis of the hydration treatment of deficient milk secretion, may thus be an actual hindrance to lactation. Moreover, as GUNTHER has lately pointed out[1] the flooding of the body with water is likely, on its own account, to antagonise the draught reflex CROSS[2] has shown that the draught is accompanied by another posterior pituitary effect—the antidiuretic action. If diuresis has been forced on the body by water drinking the secretion of the posterior pituitary antidiuretic substance must be impaired, even though its accompanying effect of *producing contraction of the myoepithelial cells would* be appropriate

Despite these physiological considerations, the custom prevails of persuading mothers to drink large volumes of fluid Six pints of water in addition to tea, coffee cocoa, milk and soup is not an unusual daily amount Some mothers complain that they are sick of water, and all who are taking these large quantities of fluid find frequency troublesome even when they are up and about and do not have to wait for a bedpan They will therefore be grateful to Professor ILLINGWORTH and Dr KILPATRICK who in an investigation described in this issue, have demonstrated that lactation is hindered rather than helped by much drinking They found that mothers who drank only as much fluid as they felt inclined were able to give more milk on the ninth day after delivery *than a comparable group of women who* deliberately took nearly six pints a day Those who were left to their own inclination took an average of about three and a half pints daily So we would be wiser and kinder to offer, rather than prescribe fluids at the time of lactation.

CHOOSING UNDERGRADUATES

RACE HORSES, uncertain, coy, and hard to please, are notoriously rough on the prophets, but compared with entrants to university education they are models of predictability Those who have to assess, in advance and on short acquaintance, the likely performance of a horde of young persons wearing the muffin-like mask of adolescence, are confident—like other followers of form—of their flair for picking winners

But such evidence as we possess by no means fully justifies their faith in themselves According to a new P E P broadsheet,[1] few studies have been made of the causes of failure of students (defined, that is, in terms of failure to get a degree), but at a conference of the Home Universities last year Sir Alexander Carr Saunders gave some results of an analysis made at the London School of Economics

> In 1949, 305 full time students were admitted to the school to read for the degree of B SC (Econ) All should have taken the degree in 1952, but only 207 did so Of the 98 who did not, however, 33 were not 'failures "—they transferred to other courses or withdrew for personal reasons The remaining 65 failed at examinations at the end of their first, second, or third year Only 1 did, in fact, fail in the third year, at the final examination The interesting thing, however, is that, at entrance, 27 (41%) of the 65 failures were considered to be first class, and 31 to be good, the remaining 7 were thought to be adequate

A parallel study was made by the Working Party on University Awards,[2] who found that of the undergraduates of one university who took good degrees (firsts or good seconds) from 1935 to 1941, 46% would not have qualified for awards on their marks in the Higher Certificate examination

At the moment, there are available every year 2000 State scholarships (including 30 scholarships for mature students and 120 technical scholarships) The Ministry of Education have undertaken to supplement up to 2000 open university scholarships of an annual value of £40 or more, and so far there are 1400 of these In addition, there are 8800 major awards by local education authorities Of the 22,000 undergraduates entering universities in 1951–52, over 15,000 were assisted with public funds from one or other of these sources The idea is that the university awards supplemented by the Ministry should go to outstanding students, selected by competitive examination, while the local authority awards should provide for the good average student Each of the 146 local education authorities decides the number of its awards, their value, and the conditions on which they are made, but only 40% of the money comes from local rates—the rest is provided by the Government When it comes to deciding who is to have awards, the universities not unnaturally think that they should pick their own entrants, and that any young person who, in their opinion, is good enough to be offered a university place is also good enough to be offered a local authority award—which, indeed, should come to him as a matter of course The local authorities not unnaturally think that as they are providing nearly half the money for their awards they should have the right to say who will get them Many make an award conditional on the candidate's getting a university place, but it is not unknown (though it is unusual) for a student who has been accepted by a university to be subsequently refused an award by the local authority Moreover, according to the local authorities, the universities are not necessarily the best pickers P E P quote a correspondent

> 'Local authorities are noticing an increasing number of rejects after the first year in a university Every reject means that anything between £150 and £250 has, so to speak, been thrown out of the window In fact some local education authorities have doubts (and some of them considerable doubts) about the selection procedure of some universities"

Generally speaking the universities base their decisions on the young person's school examination performance, supplemented in some cases by his success in a college entrance examination, on his school record and testimonials, and usually on an interview Some of the larger universities do not attempt to interview all candidates, the numbers seen range from 10% to 80% Those universities which use the interview for all candidates prize it highly as a selection procedure The universities themselves are the first to admit that existing entrance tests do not measure the candidate's power of adapting himself to a new environment, a new approach to subjects, a different method of study, and the other changes implied in the transition from school to university And again, what is success? Is the final examination of the university a good enough criterion? P E P quote a statement by the Civil Service Selection Board that the 100 candidates whom the board placed at the bottom of the 3000 they examined over a period of three years included 60 who had been university or college scholars, 20 who had held State or county scholarships, and 10 who had first class degrees It seems that the criteria applied in the university do not necessarily overlap with those applied elsewhere

In this puzzling situation P E P come to the conclusion—in some ways unexpected—that responsibility for selection should rest solely with the universities, and that the granting of an award should automatically follow the acceptance of a student by a university This could be arranged, they suggest—and no doubt they are right—if the Government assumed full financial responsibility for all awards and not merely for 60% of their cost, as at present All candidates, they say, would then have at least an equal chance of being considered for a place They also think there might be a more liberal policy of admissions to the university followed by a more rigorous weeding out at the end of the first year, when those unlikely to complete the course are more easily detected (The effect of such a measure on the suicide rate among undergraduates is a matter for speculation it might, of course, reduce it) But even if the grumbles of the local education authorities were thus effectually silenced, the general public would surely deserve some assurance that the best boys and girls were getting the awards, and that money was not being wasted The universities recognise that their methods of selection fail to take into account some of the qualities which go to make a good student, and research on selection problems is now in progress When the results of the Nuffield Foundation and Medical Research Council inquiries are published they will no doubt influence not only techniques of selection but also the content of university courses, and methods of teaching We must not, however, expect miracles, even then it is most unlikely, as P E P are careful to point out, that these findings will produce "a single compendious test which, applied at the school-leaving stage, will enable accurate forecasts of performance to be made"

A HAZARD OF ANÆSTHESIA

AN endotracheal tube is generally regarded as a certain safeguard against the possibility of respiratory obstruction during anæsthesia Its everyday use has not only safeguarded many lives, but has made many operations incomparably easier—particularly those on the head and neck Even an endotracheal tube, however, may be kinked, or, as in a recently reported fatal case,[1] obstructed by an inflated cuff Anæsthetists ho have not already given thought to this possibility hould note that an inflated cuff may block the end of n endotracheal tube if the lower edge of the cuff is ose to the end of the tube and the rubber of the cuff very thin It may also block a soft endotracheal ube by compressing the lumen of the tube Softened ubes—usually the result of long boiling and greasy ubricants—should be discarded

WHO IN AFRICA

FOLLOWING a general policy of decentralisation, W H O ransferred its African regional office from Geneva to Brazzaville in October 1952 and the director of this ffice has now reported on the first year's work [1] The ifficulties of recruiting an international administrative nd secretarial staff for work in Africa have been made worse by placing the office in one of the most expensive owns in the whole world (W H O have had to rent partments for their staff at $285 a month) the town acks a reliable supply of water and electricity, and the mall staff have had so many purely domestic problems hat it is remarkable that they have been able to get round at all Nevertheless, the director, the public health medical officer, the sanitary engineer the health nspector the nurse, and the cultural anthropologist, who comprise the main executive part of the staff have all toured widely They have started to persuade the various African governments of the advantages of coöperation in international health and have initiated local educational projects. The account suggests that the Organisation still demands from its staff some of the adventurous spirit of the nineteenth-century African pioneers.

In the second half of the report the director Lieut General F Daubenton, allows himself on retirement after three years of office, some general reflections on health work in Africa. He points out that without the help and coöperation of enlightened Africans all foreign plans must fail No large-scale plans for technical or other development in Africa should begin without profound study and research, *Festina lente* is the motto recommended for enthusiasts The African village will for a long time be the site of the most important health problems and here he quotes Dr J M Karefa Smart one of his staff

> "The sense of community is paramount. People do not live for and to themselves in the village. All ethical values derive from the demands of what is good for the community and for the most part individual goals and objectives are tolerated only if they contribute towards and do not conflict with the goals and objectives of the community as a whole Secondly an understanding of the village permits of no division of the life into separate compartments. Just as there is in the mind of the villager no interruption in the continuity of life, from the spirit world at birth back to the spirit world at death, so there is no separation of the economic or material from the spiritual components of village life All of life is one.

Thus no scheme should be started unless its purport has been thoroughly explained and the coöperation of the villages concerned effectively secured Otherwise material will be unappreciated and machines and machinery foreign to their ideas will be neglected

In Africa today it would be better to have early twentieth-century medicine widespread, rather than the most modern forms of treatment within the reach of only a few In his travels General Daubenton has seen an X ray plant where there was no reliable electricity an elaborate obstetrical table unused while the 'bearing down' rope attached to the ceiling badly needed replacement and heavy dental and other equipment imported before the local roads and bridges could support them These errors could have been avoided by more thought and less hurry Industrialisation in Africa has started and will go on Africans themselves ask for it but only a few of them may realise how industrial development will alter their philosophy, their traditions, and their social culture Undoubtedly the most important task before W H O in Africa is educational. But all forms of medical training must do more than teach techniques for new techniques will have to be integrated with a social philosophy adapted to a new Africa and acceptable to Africans

THE SEAWEED FLIES

DURING the past few weeks South Coast towns have been much troubled by a spreading plague of flies breeding on seaweed The insects have been identified as belonging to the genus cœlopa,[1] which has long been recognised along the Atlantic seaboard of Europe from Spain to Norway The fact that it has not previously made itself a nuisance explains why little is known about it other than its morphology The present invasion is a new phenomenon which started in late August and grew to much greater proportions during September and the mild weather of October The flies and their larvæ have been detected in seaweed and especially in the shingle on beaches from Dorset to Kent and they have spread to the Home Counties probably in loads of shingle carted inland as building material Attracted by certain hydrocarbon compounds, the flies have swarmed in dry-cleaning establishments, metal works, cellulose-spraying booths, and other places where organic solvents are used There is at present little evidence that they are attracted by food or refuse but it is impossible to rule out danger to the public health from this cause, for flies can change their habits.

The breeding area is that part of a shingle beach which is reached by the sea only at the highest tides in the fortnightly cycle Here below the surface of the shingle at a depth to which neither rain nor extremes of temperature can penetrate are ideal breeding conditions of saline moisture and inexhaustible quantities of macerated seaweed. The larvæ hatching from the eggs penetrate several feet into the beach, and after pupation they appear as flies, which then emigrate to the dry beach above high water mark. They seem able to complete their life-cycle in the crevices of the shingle, though warm sunshine brings them out in thousands to swarm in a frenzy a few inches above the pebbles. Sometimes they rise several feet above the beach and settle down in steady flight—always towards the east. It is this surprising habit which has led to the spread of the invasion up the channel coast.

Measures to control the plague have been hampered by lack of information about the life-cycle and habits of the fly and its larva, but energetic experiments by the health department of Brighton have yielded many useful data on the insecticides to be used and their methods of application There are two difficulties to be overcome: the rapid provision of measures to control the fly nuisance on the beaches of holiday resorts and the much greater problem of disinfestation of the tidal strip of the Channel coastline The day-to-day control of the flies in the holiday season can probably be achieved effectively enough by a suitable knock-down insecticide in the form of a fog or light spray But the clearing of some two hundred miles of coast can be quickly accomplished only if the Government takes steps to supplement and coordinate the work of the local authorities as was urged in the House of Commons last week. Coördination is necessary from the outset not only to achieve the complete success which will eliminate any reservoir of future infestation but also to ensure that the insects do not become resistant to insecticide.

---

[1] See *Lancet* Nov 21 1953 p 1106.

because of inadequate doses Meanwhile the Ministry of Health and local health authorities will be keeping a look out for any disagreeable moves by the flies, from the epidemiologist's point of view they seem to be remarkably well behaved at the moment

HEPATIC CIRRHOSIS AND PROSTATIC ENLARGEMENT

WHEREAS the secretion of hormones is exclusively a function of the endocrine glands, their excretion and inactivation, by which a balance is maintained, appear to be mainly controlled by the liver In the liver they are converted to inactive derivatives or to compounds more readily excreted by the kidneys than the unchanged hormones Although much of the recent work on this subject has been concerned with the steroid hormones, there is also evidence that thyroxine and the posterior pituitary antidiuretic factor also undergo at least partial inactivation in the liver In view of this extremely important hepatic function, it is not surprising that signs of endocrine disturbance are now well-recognised features of liver disease, especially of cirrhosis[1 2] These signs arise predominantly from hyperœstrogenism, and they include gynæcomastia, testicular atrophy, and loss of libido in men, and menstrual disorders and impaired fertility in women

Fortunately the results of hormonal imbalance are not always a disadvantage to the patient This is well shown by Stumpf and Wilens[3] in their study of the incidence of prostatic enlargement in portal cirrhosis Their figures were collected from necropsies on 333 patients with cirrhosis and 359 non-cirrhotic controls Both groups consisted entirely of men over 50 years old In the control group 53% had gross prostatic enlargement—a proportion that agrees well with other published data for this condition, but in the cirrhotic group only 30% had enlarged prostates If only the moderate and severe cases of enlargement are included, then the difference is even more striking—namely, 30% in the controls and 8% in those with cirrhosis—and becomes statistically significant Not only were those with cirrhosis less likely to get prostatic hypertrophy, but the figures also indicated that when the prostate did enlarge it did so later than in the controls For example, in the age group 50–69, the frequency of moderate or severe prostatic hypertrophy in men with severe cirrhosis was 6%, compared with 28% in the controls, whilst in the 70–79 age group the corresponding figures were 17% and 23% respectively Confirmation of this inverse relation between cirrhosis and prostatic enlargement is provided by the much greater incidence in the control groups of the secondary results of prostatic hypertrophy—e g, hypertrophy of the bladder (which was twice as common) and hydro-ureter (which was four times as common)

In speculating on the cause of these differences Stumpf and Wilens rightly say that "the condition is not necessarily hormonal in nature, yet the fact that œstrogens are not properly inactivated in liver disease suggests that these may be involved" It is well established experimentally that œstrogens can antagonise the stimulating effect of androgens on the prostate in castrated animals[4] Moreover, the beneficial effect of castration upon benign prostatic hypertrophy suggests that the stimulating effect of the testicular androgens is of significance in the pathogenesis If this be so, then the antagonistic effect of the hyperœstrogenism associated with cirrhosis could account for the lower incidence of prostatic hypertrophy An alternative or contributing mechanism may perhaps be related to the fall in 17 ketosteroid excretion in cirrhosis[5] Testosterone, which has a hydroxyl group on carbon atom 17, is much less active in stimulating the prostate than the androgens, such as androsterone, with a ketone group at C17[6] If the fall in ketosteroid excretion in cirrhosis is due to inadequate oxidation of the testosterone type of androgen to the androsterone type, then the stimulus to prostatic hypertrophy would be much reduced It is apparent, however, that until more is known of the ætiology of benign prostatic enlargement, any explanation of the inhibitory effect of cirrhosis can only be speculative Nevertheless, this effect of cirrhosis strongly supports the hormonal-imbalance theory, and encourages the view that prophylaxis, and perhaps treatment, may one day be successfully achieved by hormone therapy alone

CLOSURE OF THE LARYNX

THE comparative anatomical studies of Negus[7] indicate that the larynx is primarily a sphincteric mechanism designed to prevent the entry of water or other noxious substance into the lungs and to regulate the flow of air to and from the lungs, the production of sounds appears to be a later development Complete or partial obliteration of the laryngeal lumen during vocalisation, swallowing, and other manœuvres is usually described as closure of the glottis (apposition of the vocal cords) It is believed that the vestibular folds may prevent expiration, but they are not thought to play any part in normal phonation Muscular closure of the superior aperture of the larynx was described by Stuart[8] By means of cineradiography in the anteroposterior and lateral projections, combined with the usual method of examination, Ardran et al[9] have obtained further information on laryngeal behaviour

During quiet breathing the laryngeal lumen is wide open and little movement takes place The vocal folds are turned upwards over the laryngeal ventricles so that the airway is not obstructed When closure occurs the whole of the airway from the level of the vocal folds to the superior aperture of the vestibule is obliterated by sphincteric muscular action Complete or partial closure may take place while holding the breath, coughing, performing any act that requires rigidity of the trunk muscles, and swallowing There is also a mechanism whereby the vocal folds are turned down across the airway with narrowing of the airway above, and speech is always associated with partial closure of the vestibule and vestibular folds

This sphincteric closure of the larynx from the level of the vocal folds upwards protects the airways during the act of swallowing[10], the epiglottis turns down over the mouth of the larynx, but this happens only towards the end of the act of swallowing and after the bulk of the bolus has passed the entrance to the larynx, which may still be open at the time A little of the bolus commonly enters the vestibule and may even descend as far as the ventricle without causing coughing and without the subject being aware of the fact In normal people this portion of the bolus is always expelled on the obliteration of the laryngeal lumen when the last of the bolus leaves the pharynx Patients with a disorder of the larynx—for example, in acrosclerosis[11]—may fail to clear the vestibule of bolus residues in the normal way

MARRIAGE AND CHILDBEARING IN ELATION TO CANCER OF THE BREAST AND UTERUS

W P D LOGAN
M.D Glasg Ph.D Lond., D P.H.
IEF MEDICAL STATISTICIAN GENERAL REGISTER OFFICE
LONDON

CANCER of the breast has long been recognised as ommoner in single than in married women, and the fference has usually been attributed to the protective fects of pregnancy or lactation. Cancer of the uterus n the other hand, is commoner in married than in single omen, and one of the reasons usually given for this that childbearing increases liability to cancer of the erine cervix. Thus Gagnon (1950) found no case of ncer of the cervix in a twenty year survey of 13 000 anadian nuns. These different tendencies for mortality om cancer of breast and uterus in relation to marital atus for England and Wales in 1948–49 are shown in ble I As the age distributions of married and of ingle women are very different, the crude rate for all emales aged 15 or more would give a misleading omparison, and standardisation has been carried out y means of the equivalent average death rate—i.e., he simple average of the rates at each of the seven ge-groups shown

ABLE I—MEAN ANNUAL DEATH RATES FROM CANCER OF BREAST AND OF UTERUS PER MILLION WOMEN SINGLE AND MARRIED, BY AGE, IN ENGLAND AND WALES 1948–49

Age (yr)	Breast		Uterus	
	Single	Married	Single	Married

-64	935	738	333	318
-74	1319	1003	451	604
or more	2044	1423	567	625
quivalent average death rate for females aged 15 or more	746	552	230	308

That the relation between marital status and cancer f the uterus involves mainly cancer of the cervix is ndicated by table II, which compares mortality certified s due to cancer of cervix, body of uterus, or simply of terus without *further details of site. At older ages* he last group unfortunately greatly outnumbers the wo others. Mortality from cancer of the cervix was about wice as high in married women as in single women Cancer of the body showed little difference between the wo classes of women but what difference there was ndicated a small excess among single women The ndefined group of uterine cancers, presumably composed ainly of cancers of cervix and of body in their natural roportions, showed some excess in the married group s would be expected because of the effect of the cervix ases it contained. The equivalent average rates at ges 15 and over in tables I and II can be summarised as ollows

	Single	*Married*
Breast	746	552
Uterus	230	308
Cervix	*62*	*137*
Body	*39*	*31*
Uterus other	*128*	*139*

Since 1921 Australian mortality statistics have distinguished between cancer of various sites among single women, married childless women and married women who have borne children Dorn (1943) analysed these Australian data for various sites including breast and genital organs. For the years 1919–23 the standardised death rates per 100,000 were as follows:

	Never married	*Married without children*	*Married with children*
Breast	40	34	24
Female genital organs	*30*	*44*	*33*

From these figures it was concluded that motherhood protected against cancer of the breast, but it was also suggested that mortality among married women without children was less than among single women partly because a higher proportion of married childless women than single women probably become pregnant and in addition the mortality of married women is in general lower than that of single women

Cancer of the uterus was not shown separately for 1919–23 in the Australian data, but Dorn was able to *distinguish it separately for 1931–35* obtaining the following relatives indices, married women with children being taken as 100

	Married with children	*Single*	*Married but childless*
Breast	100	145	137
Uterus	*100*	*80*	*137*

As the Australian census of 1933 did not enumerate the two classes of married women separately, the above indices were calculated upon populations assumed to be in the same proportions as deaths from all causes an assumption which though not strictly correct would not seriously invalidate the conclusions drawn—namely that motherhood protects against cancer of the breast and that childless married women had the highest mortality from cancer of the uterus, and single women the lowest

Johnstone and Hosker (1948) also studied the Australian statistics and were led to two possible conclusions

> " (*a*) that circumstances attendant on marriage as such, in contradistinction to procreation exert some influence on cancer of the breast and of the uterus
>
> (*b*) that some obscure form of selection favours nuptiality among people less prone to malignant disease at one site or more prone to malignant disease at another

In England and Wales since 1938 information has been obtained at death registration as to whether or not *a woman who had been married had ever had children.* Those who had had children have been designated 'fertile,' and those who had not had children " infertile These terms apply not to the ability of the woman to have children but simply to whether or not she had in fact had any Analysis of the proportions of women dying infertile among women dying from various causes, including cancer of breast and of uterus have been published by the Registrar General (1947 1951) and discussed in the Statistical Reviews for 1938–39 and 1940–45 , and a much fuller analysis, based upon pro-

TABLE II—*MEAN ANNUAL DEATH RATES FROM CANCER OF* CERVIX AND BODY OF UTERUS PER MILLION WOMEN SINGLE AND MARRIED BY AGE, IN ENGLAND AND WALES, 1948–49

Age (yr)	Cervix		Body		Uterus not further defined	
	Single	Married	Single	Married	Single	Married
15–24	—	1	—	—	1	3
25–34	7	15	1	0 4	4	7
35–44	32	63	7	4	23	28
45–54	61	170	28	18	84	107
55–64	90	239	63	62	174	208
65–74	116	254	83	68	52	281
75 or more	128	207	87	78	352	341
Equivalent average death rate for females aged 15 or more	62	137	39	31	128	139

portionate mortality from all causes is given in the text volume for 1948–49 (Registrar General 1953), where mention is made of the "complex interplay of selective influences" that complicate the interpretation of the rates for the different marital and fertility classes, particularly at the marrying and childbearing ages

Although annual estimates of the numbers of single and married women of different ages in the population are *regularly available, the proportions of living married* women who have or have not had children is not usually known However, the 1% sample results of the 1951 Census (Registrar General 1952) give the proportions of fertile and infertile married women up to age 50 These proportions, together with the proportions of deaths from all causes at ages over 50 among fertile and infertile married women, have been used to calculate death rates at separate ages in relation to the populations at risk in 1948–49 for the various marital and fertility classes

That populations at risk estimated from numbers of deaths from all causes are not satisfactory at younger ages but are probably adequate at ages 45 and over can be concluded from the following figures showing the proportions of (*a*) childless married women among all married women at the 1951 census , and (*b*) deaths from all causes in 1948–49 of childless married women among deaths from all married women

TABLE III—MEAN ANNUAL DEATH RATES FROM CANCER OF BREAST PER MILLION WOMEN, SINGLE, MARRIED INFERTILE, MARRIED FERTILE, AND WIDOWED AND DIVORCED, BY AGE, IN ENGLAND AND WALES, 1948–49

Age (yr)	Single	Married infertile	Married fertile	Widowed and divorced
15–24	1	—	3	—
25–34	21	25	35	65
35–44	236	260	189	278
45–54	663	512	458	512
55–64	935	900	705	806
65–74	1310	1267	956	1111
75 or more	2044	1918	1337	1764
Equivalent average death-rate for females aged 15 or more	746	697	526	648

Age	(*a*)	(*b*)
15–	0 480	0 469
25–	0 210	0 274
35–	0 157	0 209
45–	0 206*	0 200
55–	—	0 168
65–	—	0 150
75 +	—	0 149

* Ages 45–49 only

By ages 45–54 the difference between the two proportions is negligible, and probably remains so at higher ages

Cancer of Breast

Death-rates per million women by age and by marital and fertility status are shown in table III The equivalent average rates for single and for childless married women (746 and 697 per million) were higher than the average rate for fertile married women 526 per million—i e , cancer of the breast was lower among women who had borne children Intermediate between these two sets of rates came those for widowed and divorced women 648 per million At ages under 35 the rates for fertile married women were higher than those for infertile married women This apparent reversal of the cancer risk among young women compared with old is almost certainly not fortuitous but indicates that at these ages fertile women are more liable than infertile women to die from cancer of the breast, although the opposite occurs at later ages The same sort of relationship was noted by Dorn (1943) in the Australian data for 1919–23 and [illegible] as of no importance, because of the [illegible]ers of deaths involved , but it was subsequently noted again in the English data for 1938–39 (Registrar General 1947) and 1940–45 (Registrar General 1951) Proportionate death rates for 1948–49 (table IV) confirm that there is a difference in the behaviour of cancer of the breast in relation to fertility at child bearing ages compared with older ages But, though the rates in table III suggest that the class of younger women particularly liable to die from breast cancer is the fertile married group aged 25–34, the proportionate rates (table IV), while confirming this tendency, also suggest that in the next age-group (35–44) both classes *of married women, fertile and infertile, are more liable than unmarried women to die from cancer of the breast.* Whereas there is clear evidence that after the child bearing age women who have borne children are less liable than women who have not, whether married or unmarried, to die from cancer of the breast, this relationship does not hold during the childbearing years, where childbearing or possibly the marital state itself seems to *predispose to death from cancer of the breast* The equivalent average rates for all ages over 15 are influenced mostly by the high rates of older ages, and show that the average risk is less among fertile than infertile married women , but they conceal the important departure from this relationship at younger ages

TABLE IV—PROPORTIONATE DEATH RATES FROM CANCER OF BREAST PER 10 000 DEATHS FROM ALL CAUSES, SINGLE, MARRIED INFERTILE, AND MARRIED FERTILE WOMEN, BY AGE, IN ENGLAND AND WALES, 1948–49

Age (yr)	Single	Married infertile	Married fertile
15–24	7	—	94
25–34	91	134	271
35–44	684	925	956
45–54	1071	1073	940
55–64	749	776	613
65–74	423	413	314
75 or more	199	261	185
Proportionate equivalent death rate for females aged 15 or more	461	512	472

TABLE V—MEAN ANNUAL DEATH RATES FROM CANCER OF UTERINE CERVIX PER MILLION WOMEN, SINGLE, MARRIED INFERTILE, MARRIED FERTILE, WIDOWED AND DIVORCED, BY AGE, IN ENGLAND AND WALES, 1948–49

Age (yr)	Single	Married infertile	Married fertile	Widowed and divorced
15–24	—	—	1	187
25–34	7	8	17	20
35–44	32	48	54	108
45–54	64	139	178	274
55–64	90	187	273	319
65–74	116	212	262	286
75 or more	128	180	211	301
Equivalent average death-rate for females aged 15 or more	62	111	142	211

Cancer of Uterine Cervix

The equivalent average death-rates for infertile and fertile married women were about twice that for unmarried women, the rates being respectively 111, 142, and 62 per million (table V) For widowed and divorced women the rate was 211 In contradistinction to the rates for cancer of the breast, there was no variation in the marital and fertility relationships at different ages , and, although at each age parous women fared worse than those who had not had children, the factor of marital status apart from fertility also conduced to cancer of the cervix

Cancer of Uterine Body

The equivalent average death rates in table VI indicate that single and nulliparous married women both had a ater tendency to die from cancer of the uterine body an had parous married women, the rates being pectively 39, 41 and 29 per million Widowed and orced women gave intermediate rates averaging 36 r million. Although the average rates for all ages er 15 suggest that the fertile married women enjoyed me advantage the rates at individual ages do not show is tendency with complete consistency At ages 75 d over the fertile married class gave higher rates than l infertile married women ; this exception is possibly no significance

Cancer of Uterus not Further Defined

Table VII gives the rates for those deaths from cancer the uterus that could not be assigned to either of the o more specific sites. The equivalent average rates re highest for widowed and divorced women and for ertile married women The figures are provided to mplete the picture, but, since they mainly represent ill-defined mixture of cancer of two sites where the haviour of the disease has been shown to be quite fferent in relation to marriage and fertility, it would rve no useful purpose to discuss them in detail.

LE VI—MEAN ANNUAL DEATH RATES FROM CANCER OF BODY OF UTERUS PER MILLION WOMEN, SINGLE MARRIED INFERTILE, MARRIED FERTILE, WIDOWED AND DIVORCED BY AGE, IN ENGLAND AND WALES, 1948–49

Discussion

Though the statistics given in the various tables ad in the figure indicate clearly that there are definite lations between marital and fertility status and ancer of the breast and uterus they do not necessarily nply direct causal relationship—i e. that marital or rtility status per se predisposes to or protects gainst, cancer at these sites. Several factors have o be taken into consideration before conclusions can e drawn One is the more favourable mortality xperience in general that is nowadays enjoyed by narried women compared with single widowed and livorced women Thus the equivalent average rates rom all causes in 1948–49 per 1000 women aged 15 r more were married women 18, single women 23 and ridowed and divorced women 27 A second factor is hysical selection for marriage and for childbearing, women suffering from chronic ill health are on the whole less likely to marry or if married are less likely to have children than other women This applies mainly to women dying within the age groups at which marriage and child bearing mainly occur though in the case of diseases of very long duration the influence of selection of this kind may continue to later ages. So far as cancer of the breast and uterus are concerned, the influence of physical selection may be of some importance, though not much, at ages under 45 and of even less importance at older ages A third consideration assuming that an apparent relationship is in fact a causal one is the direction in which this causal influence is operating For example, is it the marital status that conduces towards death from cancer of the cervix, or does a tendency towards ultimate death from cancer of the cervix due for instance to some hormonal diathesis, render a woman more likely to marry ?

TABLE VII—MEAN ANNUAL DEATH RATES FROM CANCER OF THE UTERUS NOT FURTHER DEFINED PER MILLION WOMEN SINGLE, MARRIED INFERTILE, MARRIED FERTILE, WIDOWED AND DIVORCED, BY AGE, IN ENGLAND AND WALES, 1948–49

Age (yr)	Single	Married infertile	Married fertile	Widowed and divorced

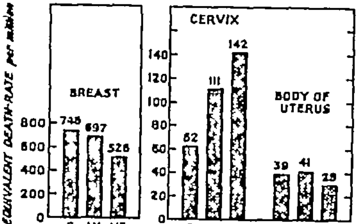
-54	84	103	107	159
-64	174	239	201	237
-74	252	331	273	334
or more	352	395	310	400
Equivalent average death rate for females aged 15 or more	128	145	138	10[illegible]



Equivalent average death-rates per million from cancer of breast, uterine cervix and body of uterus in females aged 15 or more in England and Wales in 1948–49 : S, single ; MI married infertile ; MF married fertile.

Though the factors just mentioned ought not to be ignored, their importance should not be exaggerated they are not likely to explain the very wide differences in the tabulated mortality rates for the different marital and fertility groups, and it is a reasonable conclusion that a woman's marital and childbearing experience does to an important degree determine her risk of dying from cancer of the breast and of the uterine cervix A question that remains to be settled is whether the mortality experience of fertile women depends on the number of children they have borne as distinct from simply having borne at least one. No help on this point comes from either Australian or English vital statistics, but the report by Smithers et al. (1952) on cancer of the breast gives some data concerning the actual number of fertile women aged 45 or more found to have cancer of the breast, classified according to the number of children they have had compared with the calculated expected number of women with breast cancer in each parity group The results are summarised in table VIII which suggests that it is not just the fact of having borne a child but the number of children borne that gives fertile women over 45 their reduced risk of cancer of the breast.

TABLE VIII—ACTUAL AND EXPECTED NUMBERS OF WOMEN WITH BREAST CANCER ACCORDING TO NUMBER OF CHILDREN (AFTER SMITHERS ET AL. 1952)

No of children	No of women aged 45 or more with breast cancer	Expected no of women	Ratio of actual no. to expected no.
1–3	184	154	1 19
4–6	48	65	0 74
7 or more	21	34	0 62

Summary

Death rates from cancer of the breast in women who have passed the childbearing age are higher in single and in infertile (i e, childless married women) than in fertile married women (i e, married women who have borne children) At childbearing ages, however, married women, whether they have had children or not, have higher death rates from cancer of the breast than do single women

Death-rates from cancer of the uterine cervix are higher in married than in single women at each age Marital status alone, apart from childbearing, seems to be a factor causing this higher mortality

Death rates from cancer of the body of the uterus tend to be higher in single and in infertile married women than in married women who have had children

GENERAL MEDICAL COUNCIL

SESSION, NOV 24–27

Sir David Campbell's presidential address to the council was reported last week

Dr H GUY DAIN, presenting the report of the Pharmacopœia Committee, said that sales of the *British Pharmacopœia, 1953*, totalled 25,358 The British Pharmacopœia Commission, 1953–58, held its first meeting in October

The council found the arrangements for compulsory internship by the University of Hong Kong satisfactory for registration under the Medical Act, 1950

Medical Disciplinary Committee

The committee, with the president in the chair, at its first sitting, on Nov 25, heard three applications for restoration of names to the Register

The committee, after hearing evidence, directed the registrar to restore the name of *Stewart Quarterman Servanté.*

The committee did not think fit to direct the registrar to restore the names of *Arthur James Daly* and *Sumatapalage Reginald Gunewardene*

POSTPONED JUDGMENTS

At their sitting in November, 1952, the committee had postponed judgment on *James Watson Richmond* Dr Richmond appeared and presented testimonials. The registrar was not directed to erase his name from the Register

Judgment had also been postponed on *William Pitt,* who presented testimonials The registrar was not directed to erase his name

Judgment had been postponed last November for one year on *Gerald Francis Adye Curran* In view of the testimony which he produced the committee directed the registrar not to erase his name

The committee took the same course with *Archer Wilson Dunn,* against whom judgment had also been postponed for one year

ALLEGED FRAUD

Oscar Drexler, registered as of 18, Grosvenor Square, London, W 1, M D New York (1929), was charged with having wrongfully retained in his possession £65 entrusted to him by Mr Edward Valentine Nowak for payment to an obstetrician for professional services to Mrs. Nowak's confinement In January, 1953, Mr Nowak received an account from the obstetrician He took it to Dr Drexler, whose explanation was that the money was paid and that there had been an error In May Mr Nowak received a second account Dr Drexler said it had been paid A writ was issued It was not until after a complaint had been made to the General Medical Council that the £65 was given to the obstetrician Dr Drexler, giving evidence on his own behalf, said that he the time been in the midst of domestic trouble, and glected many things. The committee determined that the facts were insufficient, and they accordingly fo Dr Drexler not guilty of *infamous conduct in a* professio respect

John Joseph Flanigan, registered as of 25, Church Str Coatbridge, Lanarkshire, M B Glasg (1947), was charged w having been convicted in the Sheriff Court, Lanarksh of causing to be posted to the executive council for the coun maternity medical service claim forms in which he preten that an anæsthetic had been administered by another doc and thus obtained additional fees His sentence of 60 d imprisonment was varied on appeal to the High Court Justiciary to a fine of £25 with the alternative of three mont imprisonment Mr J Wheatley, for Dr Flanigan, said t this was a case of careless, negligent conduct rather than intention to perpetrate a fraud on the National He Service Dr Flanigan had paid the money back to executive council That his culpability was not g was a view shared by the Lord Justice General in his judgm in the appeal The president announced that the commi were unable to accept the statement that the circumsta in which Dr Flanigan committed the offence afforded justif tion for his actions They were, however, prepared to t into consideration the assurance given for his future cond and postponed judgment for one year

William Acton MacIlrath, registered as of Wyncroft, Kn Belfast, M B Belf (1928), appeared on a charge of infam conduct in a professional respect The charge alleged tha had disregarded his personal responsibilities to his Nati Health Service patients by accepting full time employmen Cane Hill Hospital, Coulsdon, Surrey, while carrying o general practice at 222, Lewisham Way, London, S.E 4, that he fraudulently claimed and received from the Lon Executive Council grants amounting to £697 towards salary of a trainee assistant and the supervision fee when reason of his employment in a whole time capacity (which wrongfully concealed from and/or failed to disclose to Council) he was unable to give to any trainee assistant suffic supervision and/or training The N H S committee wh inquired into the arrangements for the running of his prac fined him £1000 [1] The N H S Tribunal had recommen that his name should be removed from the list, and on ap the decision of the tribunal was upheld by the Minis

After consideration in camera the President stated that committee regarded with the gravest concern the facts wh were proved They were unable to regard the statements m by Dr MacIlrath as affording the slightest justification of actions, which they regarded as deplorable Neverthel after careful consideration of all the circumstances and of assurances which had been given concerning his fut conduct, they were prepared to give him an opportunity implementing those assurances They would therefore po pone judgment for two years, until the meeting in Novem 1955, but they would expect him to appear again before th at the end of one year

Gerald Niall Monaghan, registered as of The Beeches, Alb Road, Dublin, L R C.P.I (1945), was charged with having b convicted at Shrewsbury assizes of five offences of obtain credit and of engaging in trade while a bankrupt T President announced that the committee regarded a convict of this nature as disgraceful for a medical man, but to g Dr Monaghan an opportunity to reconsider his conduct a to rehabilitate himself, they had determined to postp judgment for one year

IMPORTUNING

Ratan Noshirwan Bulsara, registered as c/o Bank of Ind 17, Moorgate, London, E C 2, M.B Bombay (1945), had b convicted at West London Magistrates' Court for persisten importuning male persons The committee felt it their d in the public interest to satisfy themselves as far as possi that the incident in question was an isolated event and r indicative of a habit Judgment was postponed for one ye

DRUNKENNESS IN CHARGE OF A CAR

Patrick Kennedy, registered as of 53, East Dulwich Ro London, S E 22, L R.C.P I (1926), appeared for postpon judgment After considering the report given by his medi adviser, the Committee decided to postpone judgment for further period of six months udgment had been postponed against *Patrick Joseph* lin registered as of 1, North Terrace, Mardy Ferndale m., M.B. N U.I (1920) who had been convicted of being charge of a motor-car while under the influence of drink e President announced that the committee had learned h concern that during this period Dr Conlin had been victed of a further offence of a similar nature Judgment further postponed for one year

---

[1] See *Lancet,* 1952, i, 260

Illiam Francis Hirsch Coulthard registered as of Balwin n, Aspatria Carlisle M.B Edin. (19-7) admitted a con tion for driving a motor vehicle when under the influence drink Dr Coulthard had appeared before the council in 6 on a similar charge The President said that the com ttee took a serious view of repeated offences of this kind they had determined to postpone judgment for one year

ugh Rinn, registered as of 324 Dudley Road Birmingham, M.B. Glasg (1923) admitted convictions in 1947 and in 3 of driving a motor-car while under the influence of drink drugs. Judgment was postponed for one year

ames William Hay, registered as of 51 Spencer Street, lisle, M.B. Aberd. (1924) had been convicted of driving a tor vehicle when under the influence of drink or drugs

Hay had been before the committee in May 1951 when gment was postponed his name had not been erased. President announced that in order to give Dr Hay one further opportunity of overcoming his tendency to drink to excess, the committee had determined to postpone judgment for one year

DANGEROUS DRUGS

Joseph Hirschmann, registered as of 118 Maida Vale London, W 9 M.B Dubl (1920), had been convicted at the court of summary jurisdiction Clun of offences of procuring pethidine Dr Hirschmann's authority to prescribe dangerous drugs had been withdrawn in 1936, and had never been restored. He had 1000 patients and was on the obstetric list for the county of Salop

Mr F P Neill counsel, said that pethidine was obtainable in 1939 but was not in common use It became popular during the war and was used in obstetrics. It had later been added to the list of dangerous drugs so that what had been a proper course of action became an unlawful practice for Dr Hirschmann. But he continued to use pethidine because he believed his prohibition covered only drugs to which the Act applied at the time of his prohibition. Under the latest regulations any midwife was allowed to prescribe this drug Dr Hirschmann had made arrangements with a deputy to prescribe other dangerous drugs. He obtained pethidine openly There was no suggestion that the drugs had been put to any improper use The committee postponed judgment for one year

Personal Papers

CHRONIC OSTEOMYELITIS

THE purpose of this account is to show how chronic deed is this disease. The duration of my own case for enty-six years is interesting, because the start was in e days when acute osteomyelitis was not uncommon children, particularly of poor economic status, and the ortality was high. Today it is uncommon, the mortality very low and chronic osteomyelitis is becoming a rity the last two facts being due to the advent of tibiotics This account will also show that I am obably right in not writing of the finish" of my case ing in such and such an era, it is, I suggest a rash ctor who pronounces a case of *chronic* osteomyelitis red.

* * *

Twenty-six years ago then, at the age of eight years, though my economic status was not unhappy and I as bronzed at the end of a South Coast holiday a dical attack of acute osteomyelitis started out of the ue in the right upper tibia. The general practitioner -forever afterwards hero and friend—was on to the agnosis like a knife. I use the metaphor purposely ecause the surgeon was not After some three weeks which the knife was used to relieve pockets of sub taneous pus and cellulitis and a severe septicæmia as fought apparently with sublime innocence and the lp of a Divinity I was moved across ngland to a teaching hospital (The emory of that journey is as clear today s it was hazy and surrealistic at the time) here my rapidly ebbing young life was aved by widely stripping and guttering he right tibia, and draining a metastatic bscess which had formed in the left rsus.

From this time, with a gradually developing bony (mercifully not fibrous) ankylosis of the right knee-joint and left ankle-joint I became a case of chronic osteomyelitis.

Two years later the sinus over the right tibia stopped discharging after many sequestrectomies, and the left ankle sinuses, after a similar history healed four years later I can recall now the day of the week on which the memorable night arrived when I went to bed without a bandage on either leg The cool sheets even now can be felt touching my ankle

The behaviour up to the present time is shown in the accompanying figure. The state of the sites is divided into five categories:

(1) *Quiescent*—This means absence of pain and the ability to lead a busy schoolboy undergraduate medical student or doctor life unhindered

(2) *Recurrence Threatened but no Incapacity*—Signifying pain and the subjective knowledge born of experience that a flare up was imminent but the current mode of life was little interfered with

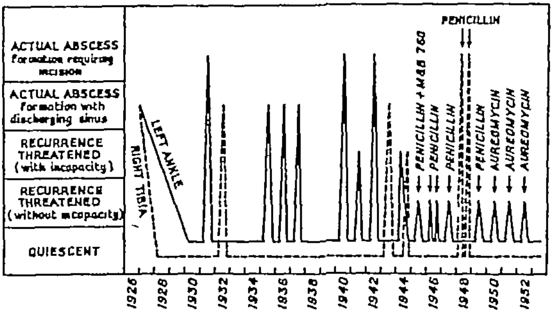
(3) *Recurrence Threatened with Incapacity*—Tenderness and muscle spasm made walking impossible

(4) *Abscess Formation with Discharging Sinus*—Usually by way of the spontaneous breakdown of an old scar or sinus.

(5) *Abscess Formation requiring Surgical Aid*—The collection of pus was localised and large

* * *

None of the recurrences lasted more than three months; the average was six weeks. There was no significant seasonal factor My general health has been excellent throughout except for an attack of acute appendicitis in 1947 I have tried to determine any cause for the recurrences. The figure shows that the only years free from these were 1933 and 1934, and 1938 and 1939 During the former I was as active as I shall ever be, no doubt, at boarding-school while during the latter I was an undergraduate and the period included a working trip to the Arctic Circle. I mention this because using



Course of illness, showing treatment of recurrences.

the affected limbs or parts somewhat rigorously is not therefore a cause, as is often claimed in teaching What is interesting is that the total recurrences of all kinds in the ten years preceding the beginning of the late war were 5 The total in the next ten years was 13, although 4 were "threatened but non-incapacitating" Perhaps the rather strenuous mental and physical working conditions during and after the war years had something to do with it

The other striking feature shown by the figure is that since 1945 there have been 10 recurrences The responsible organism is *Staphylococcus aureus*; and penicillin, and latterly aureomycin, have been used in big dosages with each warning of a flare-up In the case of the left ankle it will be seen that no recurrence has reached the "incapacity" level The right tibia, however, on 2 occasions (and the only 2 in the same year) broke loose and reached the operation stage (We even tried—my long suffering and patient colleagues and I—intra-arterial penicillin on the first of these occasions, via the right femoral artery The idea was to produce a sudden great concentration of penicillin in the by-now hyperæmic guilty cavity area Perhaps it did, but it did not stop the march of events For those interested, it *did* produce a great amount of temporary pain and the sensation that the lower limb was alternatively going to blow up or possibly melt with fire I hasten to add that my friend the surgeon who gave the intra arterial injection did so against his normally perfect judgment, but I was so difficult and unpleasant to him that I upset this quality I only hope he has by now forgiven me for the subsequent nightmares I later learned that he had suffered—the general theme running on the lines of arterial spasm→ gangrene→amputation)

* * *

In 1949 I became sensitised to penicillin and suffered an attack of giant urticaria, œdema, and pyrexia all rolled into one From then onwards aureomycin has been used By inspection of the diagram, it does seem possible, then, to keep the recurrences down on the lower level, at least in the case of the left ankle, but not to lessen the recurrence *rate*

Other points worth mentioning are that, as shown in the case of the right tibia, a quiescent period of eleven years can lull you into a false sense of security, that, in the great majority of the attacks, general constitutional upset lasted only a few days at the beginning of a recurrence, and that pyrexia has always been strikingly absent, as has sequestrum formation after the original healing One recurrence was ushered in with great ceremony by a rigor, but this sole occurrence led to a very minor affair

* * *

The most pertinent question is, How can you stop recurrences altogether? All authorities agree that the great obstacle to treatment is the fact that cavities and infected bone are very difficult to reach with antibiotics carried in the blood stream, for extensive thrombosis of the nutrient vessels and stripping of the periosteum occur in the early attack (Altemeier and Wadsworth 1948) Many methods of treatment have been tried those of Winnett Orr (1927), Baer (1931), Albee (1933), Kornev (1937), and Buchman (1937) are examples of the many diverse techniques from maggot therapy to staphylococcus toxoid The sulphonamides have not been very successful in the treatment of chronic osteomyelitis The only radical cure seems to be to remove all infected bone and to saucerise all cavities, at the same time bringing antibiotics into direct contact with the areas This is advocated and described by Basu (1951), using aureomycin as the antibiotic, but his follow-up period in 30 cases with no recurrence was never longer t[illegible] six months, and a glance at the figure will show why [illegible]st wait a considerable time before judging the efficacy of this method The surgical difficulty of removin all possibly infected bone is great, especially in long standing cases of extensive bone involvement

The possible mechanism of preventing recurrence becoming incapacitating is that, when a flare-u threatens, the area becomes inflamed and there is great increased vascularity This aids the carrying of a antibiotic to the required area In most recurrences i will at least apparently prevent an escape or extensio of the infection It does seem, however, that, even i shamefaced, the organism returns to lurk behind a avascular wall It is hard to have to wait for a reappear ance before dealing with it, but there it is. At present then, it looks as though aureomycin, which has bee shown to be particularly effective against coagulase positive *Staph aureus* (Nichols and Needham 1949), use systemically has a place in the treatment of chron osteomyelitis

* * *

For obvious reasons this essay must be anonymou I want to take this opportunity of expressing my dee gratitude for constant skill, patience, and kindness fro so many doctors and friends, and to my parents an wife But, alas, they must all be anonymous too

Medicine and the Law

A Transfusion Accident

In an action [1] before Mr Justice Hilbery and a jur in the Queen's Bench Division, the plaintiffs sought t prove negligence in the administration of a bloo transfusion to a 26 year old man on the day of his deat The man's parents claimed damages from the Southen group hospital management committee, and the counsel brought evidence to show that the blood use in the transfusion was infected and that death wa caused by "toxæmia due to infected blood" and not b incompatibility

The patient was admitted to Southend General Hospita on Oct 28, 1951, and an operation for hæmorrhoids wa performed The operation was successful and it was no until a week or so later that repeated bleeding made i necessary to give him transfusions. The fourth trans fusion on Nov 18 produced rigors, nausea, and pyrexi and had to be abandoned The patient recovered fro this reaction, but he was still very anæmic, and the senio surgical registrar thought it was advisable to give hi more blood in case he had another hæmorrhage afte leaving hospital On Nov 21 the fifth transfusion wa given rigors, nausea, vomiting, and pyrexia followed By 5 P M that day the patient's temperature was ove 103 and his pulse was imperceptible Despite a treatment, he died at 8 P M

A pathologist from another hospital, who had carri out a post mortem examination on Nov 26 at th request of the coroner, said that his conclusion was tha death had been due to the presence in the blood-stream o bacilli "foreign to the body but commonly found i water and soil" The organism isolated was a moti gram-negative rod which grew well at 20°C but hardly a all at 37°C—probably an atypical coliform There wa no question, he added, of the blood-groups being incom patible In the circumstances, he thought that every thin pointed to the fact that the blood given in the transfusio ov 21 contained an enormous number of organisms reply to a question from defendant's counsel he ed that fatal reactions could be caused by the ence in the transfused blood of dead bacilli which ld be extremely difficult to detect. This could happen out negligence on anybody s part

---

[1] *Times* and *Manchester Guardian*, Nov 26, 27 and 28, 195

he pathologist at Southend General Hospital said from the tests he had performed he had concluded the patient's reaction to the non fatal transfusion of 18 was due neither to incompatibility nor to ction. He was not surprised that evidence of infection been found in an examination carried out five days r death. He thought it likely that the blood stream been infected from the operation site On the data lable, he was unable to say that the patient had from toxæmia due to the transfusion of the infected od, something in the blood had been responsible but he moment he could not say what. It was stated the blood used for the fatal transfusion was later cked and rechecked for sterility and compatibility was found to be correct Unfortunately during the for the patient s life the bottle was left uncapped he ward, and it was later found to be infected.

he patient s family doctor also gave evidence He ted the young man on Nov 20 when he seemed much ter and was expecting to leave hospital shortly He reluctant to have another transfusion but he was suaded to do so In his doctor's view, the transfusion Nov 21 after the reaction on Nov 18 was an error of gment. He agreed that two hæmorrhages after such operation was a serious matter, but he did not think t a hæmoglobin of 40–44% was dangerously low

t was stated for the plaintiffs that the action was inally brought also against the house-surgeon who given the transfusion This doctor could not now be ced, and counsel for the plaintiffs sought to show that was not registered with the General Medical Council the time in question, though, as Mr Justice Hilbery erved, this was irrelevant to the issue of negligence, the house-surgeon was fully qualified and the M.C. would have granted registration had he applied it.

iving judgment for the defendants, Mr Justice bery said there was no evidence on which a jury could sonably find for the plaintiffs The allegation that the spital was negligent in entrusting the transfusion to a ng man recently qualified was absurd particularly ce the evidence was that, in the opinion of highly alified surgeons under whom he worked, this young ctor was exceptionally competent. The allegations in s case indicated recklessness in making charges of gligence. There was nothing to show that the bottle question had become infected because of the way in ich it had been handled by the house-surgeon or anyone e.

Public Health

Eire in the Second Quarter

In Eire during the June quarter of this year[1] the birth-te was 22 8 per 1000 population this was 1 0 below e rate for the second quarter of 1952 The death te was 12 1 per 1000 population (0 3 above that for the cond quarter of 1952) The death rate from tuber-losis was 0·5 per 1000 population (respiratory 0·4 ther forms 0 1), compared with 0 6 (0 5 and 0 1) in the cond quarter of 1952 The maternal mortality rate s 0·7 per 1000 births registered compared with 3 for the second quarter last year; and the infant-rtality rate was 41 per 1000 compared with 35 for e second quarter last year

In England Now

A Running Commentary by Peripatetic Correspondents

THE electric telegraph the telephone, and wireless rank high among the great inventions of the past century But, as I have learned, our precipitate progress has not stopped there. Let me first trace in the background

My wife and the milkman have never been on terms of close accord For some years after the war he purveyed as well as milk, such rare delicacies as butter and eggs; and unruffled by the Minister of Food's dispositions he offered these to all who would buy Perhaps he was nettled by my wife s refusal to enter this *marché libre* but they got on well enough until she found that the wealthier customers could also obtain limitless milk and that our weekly portion was falling 2 pints short of what the Ministry deemed fair The ensuing scene ended all hopes of rapport. Each summer our milkman journeyed to Switzerland while we took ourselves to the Isle of Wight; but as time went on his market crumbled and last year we met him on the plage at Ventnor, and to our earlier differences is now added his bitterness at being *dragged down to our level* Accordingly my wife a tireless gadgeteer, began to cast around for an impersonal means of communicating her wishes to him, and she lighted on the answer This is a small half moon disc with a pointer that can be directed at anything from '10 gallons' at one end to ' none ' and " please knock at the other For a few days this device worked splendidly Then, one morning, we found 12 pints on the doorstep Taxed with this the next day, the milkman pointed mutely to the arrow and sure enough he had obeyed its instruction For three more days all went well but then he passed us by without allotting us so much as half a pint, and again we found that he had obeyed the machine A few mornings later the bell rang and on the doorstep my wife found the milkman. Each eyed the other watchfully Well?" said the milkman Well? said my wife The arrow was at please knock' This led us to examine our first premises. Did the fault lie with the machine or with a human element of which we had not taken account? Careful thought led us to conclude that the machine was not to blame There remained that vital human element Action followed swiftly I told our three little cherubs that the wind which next blew the arrow out of place would blow away their next Saturday's sixpences Now the machine is working perfectly

* * *

Those who view the elaborate armamentarium of the modern neurosurgeon with alarm and who secretly wish for the renaissance of a less complex surgical technique will be encouraged by a report[1] of an operation lately performed in Peru Two Peruvian surgeons had been interested for some time in Inca skulls, particularly those with trepanning holes; it seems that the Inca surgeons of 2000 years ago used stone chisels or knives made of obsidian for these operations. Using the ancient tools, the present-day surgeons have successfully removed a blood-clot from a patient s left parietal region They add that they were readily able to control bleeding from the scalp by the use of an ' Inca tourniquet —a one-inch wide bandage wound tightly thrice round the head Postoperatively the patient was given antibiotics—a sensible gesture although one calculated to annoy purists of primitive surgery

* * *

The help given to the National Health Service by doctor's wives is in my opinion not sufficiently recognised. True there is some appreciation of their book keeping and other auxiliary services for income-tax purposes. But I refer to their far more important *medical* work. I know of several like myself who, though without formal medical training, are much sought after for diagnosis, prognosis, and treatment or just for really authoritative advice. The reasons are obvious. In the first place we do not have to keep patients from asking awkward questions: such knowledge as we have, we share freely

---

[1] *New York Times* Oct. 4 1953.

We do not need to examine our patients, nor do we even have to see them we can be conveniently consulted on the telephone or by post Unlike our husbands, we are unhampered by professional etiquette (Only last week did I have to tell a friend what I thought of Dr X for prescribing penicillin in a mild sore throat and to caution her against administering it to her little boy) Finally, we welcome inquiries on any medical subject and remain unaffected by the growth of specialism For instance, I feel I can be of help in such varied matters as boils, insomnia, bedwetting, ulcers, and slipped discs, though I must admit to a predilection for more obscure medical diagnoses involving less well-defined symptoms that baffle orthodox practitioners. Unfortunately in recent years, my friends, shopkeepers, and dailies present me increasingly with psychiatric and psychosomatic problems in which rapid success cannot be hoped for

But perhaps our greatest responsibility is in prescribing for our husbands "Are two aspirins enough, dear ?" mine asks me anxiously before embarking on a course of self-medication Where, indeed, would the Health Service be without us ?

* * *

A colleague of ours in the States whose interests run to comparative physiology told us of a harassing experience It appears that our colleague became interested in the matter of beavers, but was unfortunate enough to live in a virtually beaverless part of the country Accordingly, he issued an appeal to those of his friends who were more happily situated, and eventually his entreaties were answered by the totally unheralded arrival of a fine pair of beavers, escorted by a sceptical Railway Express man

The beavers had arrived, as beavers will, after all the technicians had gone home , and our colleague was at once placed in some difficulty, for the animal house was shut and he had no key However, he is a man of some resource, and he remembered a disused bathtub up in the attic He had no first-hand knowledge of the care and maintenance of beavers in bathtubs, but he had a vague idea that they would be happier with some water in the bath, so he dragged it over to a place where he could fill it from a convenient tap, and brought the beavers up to admire their new home Unfortunately the bath had in the course of time become detached from its plug, and our colleague cast about for a substitute Eventually he had a Machiavellian idea, and retrieved a large carrot from a bag of food outside the animal house With this he plugged the bath, partly filled it with water and tipped the beavers in, having provided them with some food This done, he went home, tired but happy, having locked the door on his charges

We need scarcely proceed further They *did* eat it , there *was* a flood In fact, the only unexpected feature of the proceedings was that the professor's desk was so nearly vertically under the bath The resulting interview was full of physiological suggestions, and at its close our friend found that rats would suit his purpose equally well

* * *

An important technique of the Bed-end Manner is the printing of the patient's name on his temperature chart in large block letters, legible at least two bed-ends away One can then say "How are you, Mr Blank ? and get undeserved credit for knowing every patient by name, as long as they stay in bed During the war when I had temporary charge of 1700 patients (in a 1400-bed hospital) I found it invaluable I could leave scientific impartiality to my junior officers with a good conscience In my old-fashioned way I sometimes thought my personal interest did more for some patients than the brilliant technology of my more gifted colleagues

Get someone more sprightly and glib
I ll sit, if I must upon boards till I bust
Or committees *ad hoc* or *ad lib*
But my cerebrovascular fittings
Are cobwebbed and riddled with rust
So if you are bent on this Brains Trust, Miss Denton,
 hold of some brains you can trust

Letters to the Editor

OPERATING-THEATRE INFECTION

SIR,—Your leader last week puts the responsibility eliminating operating-theatre infections squarely on t shoulders of surgeons I am not at all sure that surge alone can solve this problem

Dr Sevitt has reported in two articles—one in 194 and the other last week—3 major operating ro infections (1 of them fatal) occurring in a suite operating theatres in which over 10,000 operations h been performed during this period His investigati were asked for by the surgical staff of the hospi concerned, and his evidence accepted

In the same hospital there exists a dressing station the large wounds of burns and scalds, fitted with positive pressure ventilating system of clean air (enter at ceiling level and finding its exit at floor level) controlled trial of this system has confirmed that it only greatly reduces the number of organisms pres in the air but prevents major infections of burns dre with the ventilation plant running, and apprecia reduces minor infections This evidence, too, is kno to the surgical staff

What action then could these surgeons take on t evidence ? We made several attempts to minimise flow of contaminated air to the theatres , we re desig the facilities of the sterilisation service, and the flow clean trolleys to clean theatres and the disposal of d material away from the theatre, in an endeavour increase the ease of work and the efficiency of the thea staff as a whole These attempts were not successful preventing operating theatre infection

We are now of the opinion that a radical re design of our operating-theatres is essential to lessen the kno risk of airborne contamination, and this for the follow reasons

1 The dust of hospital wards and corridors inevita contains more bacteria than that of a normal building , despite most careful cleansing precautions, this must alw be so

2 The operating theatre suite is almost always within hospital building, sharing the air and dust of that building

3 *With some types of ventilation in operating theat (such as ours) air is sucked from the hospital building it and drawn into the theatre suite,* thus ensuring the maxim contamination of the operating theatre air

The ventilation plant of all operating-theatres, the fore, needs to fulfil certain requirements

1 The source of air should be above hospital level so as avoid contamination from the air of the hospital a incidentally, from the street The air inlet on the roof of Accident Hospital has proved satisfactory to the Burns U installation

2 The flow of air to the theatre should be such as to prov up to 20 complete changes per hour

3 Filtration of the incoming air is necessary to remove a soot or bacteria-carrying particles

4 The temperature and humidity of the incoming air sho be automatically controlled, both for the comfort of patient and staff and to minimise anæsthetic explosion ri A temperature of about 70°F and relative humidity of 6 is satisfactory for these purposes

5 Since the exhaust air from such a theatre is potentia contaminated it is necessary to remove it to the exterior T must be done without inducing a negative pressure, wh would draw in hospital air from the corridors Similar c siderations make air locks desirable for patients, staff, materials to pass in and out of the air conditioned section.

6 Since preparation work involves steaming sterilis separate ventilation of rooms doing this work is need preferably with an input of the same filtered air that is suppl to the theatres and an independent output carrying the ste laden air to the exterior It is important that air potenti

---

1 Sevitt, S *Lancet*, 1949, ii 1075

amminated by passage through the theatre should not be lied to preparation rooms, since this may cause con nation of instruments and equipment to be used for the or subsequent patients

rom this evidence it is obvious that surgeons alone ot meet this quite formidable engineering challenge. the matter does not end there. Since this method entilation is only an additional precaution against ating room infection, the lay out and design of the tre suite must provide the usual aseptic and antiseptic autions against infection. The emphasis now is on a air; therefore a revision of the detail of operating tre lay-out and design is essential on two counts:

All sources of dust collection must be radically eliminated
The maintenance and physical cleansing of all equipment ne normal theatre maintenance staff must be easy—even a complicated problem than it is now

the elimination of all sources of dust collection, no pment can be allowed to hang from the operating tre ceiling For example the present umbrella ed high power theatre lamp hanging immediately re the operating table is often tilted during an ation; and with positive-pressure ceiling ventilation lean air this would result in the immediate con mination of the operation wound with the dust from top of the lamp

addition, all equipment—tables trolleys, and so -that is too big for autoclave sterilisation should be nly designed for ease of washing or spraying with a able antiseptic and wiping down, and such articles ld have no shelf near floor level The ceiling, walls, floor must also be cleanly designed and have no ks or crevices in which dust can collect. Here, then, hospital architect s problem

n adequate source of lighting is essential to all ations, accordingly lighting presents particular blems when it is accepted as a principle that all ting must be *behind* the cleanly designed non-dust- ecting ceilings or walls Thus, involving high quality face and depth lighting of the operation field as well good general lighting, is a major problem for the ting experts.

ster was aware of all these needs for theatre cleanli , and met them as best he could, as have all surgeons e his day Now, however, with our increased know e the task is beyond any surgeon s ability to answer m. The Birmingham Regional Hospital Board has pted the need for a small and closely knit team of pital architects, engineers, and lighting and air ditioning experts to work with a surgeon to meet the ny-sided aspects of this matter The group has rted work and see no reason why operating theatres ld not be quite safe from any major infection; and, thin the bounds of human failings, minor infections ld be considerably reduced.

Your leader states that the essential clean-air plant d I believe we have the only one in the country) ' is pensive to put in and to run.' Our experience in the of this plant is that its capital cost was small and was turned within two years by the considerable reduction wound infection that it effects. The plant is easy and eap to run; the only maintenance necessary is a thly change of inexpensive filters and the running of a horse-power motor In the past eight years it has en used daily without any major breakdown. Any dern operating theatre is costly to build and the dition of a clean-air plant, though adding slightly to e expense, could not be seriously objected to in view its proved usefulness.

Dr Sevitt has recorded the tragedies of 3 major wound ections—an incidence of 0 03% of all patients operated over the period of his inquiry He has not recorded more common minor and trivial infections yet these known to increase significantly the period of inpatient treatment for the patient, and to add to the risks of cross infection in the ward in which he is nursed.

Wound infection of any type is an *expensive* complication From a purely economic aspect, it is always cheaper to prevent than to cure

Birmingham Accident Hospital. WILLIAM GISSANE

SIR,—In his discussion last week of the possible sources of infection in a case of gas gangrene developing after operation on a closed fracture Dr Sevitt says: "Since the original fracture was closed the leg muscles are unlikely to have been contaminated by *Cl welchii* before the operation on the ankle " I was most interested to read this because I have recently treated three cases of gas-gangrene in patients with closed fractures.

Case 1 was a young boy seen four days after receiving a third degree abduction external rotation fracture of the ankle The ankle was grossly swollen and fracture blisters were present The skin was however intact Two days after admission he had developed gas gangrene and below knee amputation was performed

Case 2 was a man with a spiral fracture of the shaft of the humerus, who attended seven days after injury There was no breach of the skin, but he had gangrene of the arm and gas bubbles could be felt over an area extending from the mastoid process to the iliac crest and from the sternum to the vertebral column. The arm was amputated through the shoulder joint

Case 3 was a man with a closed fracture of the shafts of the tibia and fibula. When he came under my care seven days after injury he had gas-gangrene extending as high as the knee Above-knee amputation was performed.

These patients were seen in the Sudan in 1951 and 1952 Before seeing them I was quite ignorant of the possibility of gas gangrene developing in the absence of a wound of some sort, but senior members of the staff of the medical faculty of the University College of Khartoum to whom I turned for advice told me that such cases are by no means uncommon in the Middle East

Newcastle upon Tyne P R R CLARKE

SIR,—In about July, 1917, Mr W McAdam Eccles was distressed by a series of infected wounds in his habitually clean cases. The bacteriologist (the late Dr Canti) placed a number of open petri dishes on the operating table and switched on the ventilating fan. A variety of organisms were sucked under the door from the mat outside and were demonstrated by culture. Since a war was in progress use of the ventilating fan was stopped and we endured the heat I think that this particular theatre was abandoned or replaced after I left the hospital.

Newland, Sherborne
Dorset. JOHN WHITTINGDALE

HYPOTHERMIA

SIR,—In the article on surface cooling by Churchill Davidson et al (Nov 14) and in subsequent correspondence (Nov 21) there has been a notable omission of any reference to the indisputable fact that a generalised and highly efficient response to cold exists in the non hibernating warm blood animal when subjected to any form of surface chilling That this response involves initial increases in heat production and oxygen requirement is well established and only by imposing the added risks of heavy sedation, deep anaesthesia and muscle-relaxing drugs can this calorigenic reaction be even partially inhibited and hypothermia obtained Even under these conditions, while surface tissues are reduced to levels of cold that may cause permanent damage, deeper tissues may not be equally cooled and consequently thermal gradients are likely to arise within the body These have been shown to have among other disadvantages that of increasing the incidence of cardiac arrhythmias. Other undesirable changes occur as the result of surface cooling, including a lowered circulating lood volume, hæmo concentration, increased blood iscosity, hyperglycæmia, eosinopenia, and depletion f adrenocortical lipids and ascorbic acid This widespread physiological upheaval is not seen when hypothermia is induced by cooling the exteriorised circulation,[1] nor has death or tissue injury followed in over 100 experiments in dogs The method requires only the lightest anæsthesia, and premedication and muscle relaxants are unnecessary Hæmodynamic disturbance does not result from the arteriovenous shunt due to a balanced resistance in the exteriorised circuit Despite reports of successful application of surface cooling in relatively small numbers of cases, the accumulated experience in both clinical and laboratory trials has been that this procedure is hazardous and associated with a considerable mortality

A more complete understanding of what has been called "cold stress"—a complex physiological derangement known to follow surface chilling—should be sought before the method is proposed for further clinical trial In infants and children, the greater surface area relative to body mass and the poorly developed heat-regulating mechanism may, as suggested in your leading article of Nov 14, make surface cooling in children a safe and effective procedure

E J DELORME

Department of Surgery
University of Edinburgh

INCISION FOR ACUTE APPENDICITIS

SIR,—Mr Ewing and Mr Monro (Oct. 24) severely criticise the use of the paramedian incision in acute appendicitis Their criticism may or may not be valid, but they certainly do not make their point by quoting a solitary clinical history which could well be misinterpreted as suggesting that this particular patient had inadequate surgery or anæsthesia or both. Mr Shemilt (Oct 31) is similarly dogmatic about the absolute contra-indication to drainage following appendicectomy, but he does not attempt to justify his statement by arbitrarily selected case records

Experience in emergency surgery has convinced me that the average "early" acute appendix can be removed with entirely satisfactory results by any competent senior house surgeon through any standard incision, of which the muscle-splitting is one of the better ones The case which most tests our judgment and skill is the advanced one with perforation or gangrene, in which fæcopurulent exudate is insecurely localised within a barrier of lightly adherent gut and omentum Here the objective should be to approach the area directly through an adequate incision, guard its delicate margins with moist packs, and remove the appendix under direct vision and with careful suction control Fortunately the majority of these cases show maximum tenderness and splinting laterally in the right iliac fossa, and in most of them a mass can be felt in this region when the patient is anæsthetised In these circumstances, no surgeon in his right mind would employ an incision other than one in the right iliac fossa, and my own preference is for the ample exposure offered by the oblique muscle-cutting approach of Rutherford Morison Other surgeons, more skilful or with many powerful assistants, may achieve similar access with MacBurney's incision

But there remains a significant group in which the severely inflamed appendix hangs down into the midline cavity of the true pelvis, or in which it runs upwards and medially among the terminal loops of ileum Here, if the appendix is long and is gangrenous at its tip, the pathological epicentre may lie far from MacBurney's point. These cases can be recognised clinically, and the principles stated above dictate that the appendix should exposed directly by a paramedian incision rather than dragged out by the heels throug Drainage, if desired, can be achieved through a stab incision near the anterior superior spine, and to the iliac vessels or any other structure, from a of supple corrugated rubber so placed and soon remo is non-existent The right paramedian incision is ad tageous also in certain cases of diagnostic doubt, inclu advanced general peritonitis of uncertain though pr ably appendiceal origin. We should use it wh indicated, and should not be discouraged because operators find difficulty in coping with the bowels closing the wound securely

Finally, I envy Mr Shemilt his faith in the invin of the peritoneum, but since there are so many variab statistical proof is lacking Where the appendix shows florid sloughs, severe inflammation, and fæcal contamination I shall continue—I believe, ally—to drain it

LUNG LESIONS IN ARTHRITIS

SIR,—Your leading article of Nov 21 raises the tion of the ætiology of the nodular lesions descr rheumatoid arthritis by Caplan,[1] who is quot identifying tubercle bacilli in the fibrous tissue, lesions in three fatal cases Reference to the article, however, reveals that tubercle bacill isolated in only one of these cases Furtherm reader is left in considerable doubt about the ex of lesion from which the organisms were obtain patient (case 38) is described as showing, o examination, "progressive massive fibrosis in zones," and at necropsy "masses at the bases of the upper lobes" and microscopically "undifferen fibrous tissue in the masses" The tubercle bacilli obtained "on culture of material from a massive lesio It is also difficult to correlate the radiological with morbid anatomical and histological appearances remaining two fatal cases

Caplan prefers the theory that the lesions he descr in the radiographs ("round opacities") are bas tuberculous to the idea that they are "rheum granulomata" resembling the subcutaneous no histologically In this respect he has the suppo most workers who have studied the lungs in fatal of rheumatoid arthritis. My own experience of 7 cases of the disease is in agreement with the that no specific lesion occurs However, there is su resemblance between the histological appearance rheumatoid subcutaneous nodule and that of caseous tuberculous foci to suggest that, if one mak allowance for the different situations in which the lesions are found, their differentiation might well be difficult matter, should they both occur in the lung There is no question that Caplan's patients presented unusual radiological appearance, but the theory that "rounded opacities" are tuberculous seems, at p to rest upon the demonstration of tubercle bacilli i lesion whose exact nature is not clearly defined tuberculous lesions were present in the lungs of the two cases does not help to establish the opacities" as tuberculous

If the true nature of these fascinating lesions is discovered, it is essential that the terminology u describe their radiological, macroscopic, and histo appearances should be unequivocal Histological nation should not be considered the final st each lesion so examined should be submitted bacteriological investigation

GASTRIC RESECTION

SIR,—In my letter of Nov 7 I referred to an old method used by Rovsing in dealing with gastroduodenal hæmorrhage. I have since seen Rovsing's original communication. He described the method as follows:

> "A gastroscope constructed in principle as the usual cystoscope but of a size corresponding to Charrière no 30–40 is used. It carries a strong lamp and is provided with a canal which is connected to an insufflator
>
> At operation, a small incision is made in the middle of the anterior surface of the stomach, 2 cm. above the greater curvature just large enough to allow the instrument to pass. A purse-string suture is then superfluous. The stomach is pumped full of air until all mucosal folds have disappeared In the darkened room every detail can now be seen in the stomach as well as in the proximal duodenum. Observation of the posterior surface of the stomach is made possible by turning up the omentum and transverse colon Suspicious features can be inspected directly through the instrument which yields much more reliable information than can be obtained by *direct inspection of the opened stomach.*
>
> The method is valuable in differentiating between ulcer and tumour; the extent of a malignant infiltration can be judged with great accuracy Retrograde dilatation of the œsophagus is made easier as the bougie is introduced easily under direct vision.
>
> Its greatest value however, lies in the possibility of detecting quickly small bleeding ulcers which have not been successfully located by any other means. In 4 cases a dark *spot* was seen in the anterior stomach wall. An artery was coursing towards it, to be suddenly interrupted. It was now possible to attack the bleeding point directly ligating it from the outside by means of a stitch going through all layers and reinforcing this with one or two sero serous sutures. The method would be equally applicable to duodenal ulcers of the anterior wall."

It seems that the *short-circuit accident* which I mentioned was the result of connecting the lamp to the mains supply In subsequent cases, a battery was used.

Berne, Switzerland. P LUNDSGAARD HANSEN

GOUT

SIR,—Dr Marson's reply (Nov 21) to my letter about sodium salicylate *therapy* requires a few comments

I was sorry that he was unable to see my more detailed report [1] on uric acid excretion to which I referred because although this showed rises in the serum uric acid levels in the three-day rest after the four days of therapy the rises were moderate On the average a rise from a level of about 2 0 mg per 100 ml. to about 4·0 mg per 100 ml occurred, but occasionally the level continued to fall or remained steady The only acute attack of gout which I saw during my tests took place actually in an interval of rest from therapy in which the serum uric acid did not rise Dr Marson's figs. 3 4, and 5 show serum-uric-acid fluctuations on continuous therapy no less than those which I found in interval therapy, and his cases also had acute attacks during treatment That Bauer and Klemperer's results [2] were *less* satisfactory than mine does not surprise me, because in their trial they used aspirin, a drug whose inferiority to sodium salicylate is commented on by Dr Marson in his paper. The interval therapy with sodium salicylate as described [3] is, incidentally not so much more than sixteen years old, as Dr Marson seems to think.

I can only say that Dr Marson's belief that an initial dose of sodium salicylate sufficient to cause appreciable lowering of the serum uric acid also usually causes salicylism does not fit in with my experience in the treatment of gout and rheumatism with this drug

Dr Marson tells us that he does not yet know how long his strict regimen should be imposed and as Bauer and Klemperer also remark, our evaluation of such treatment must come from clinical results over a long period, and not be based on serum uric-acid estimations It is evident that sometimes with such prolonged treatment the patients themselves must first cry "enough" but with such a potentially painful and crippling disease there should be many who will persevere with the new method If it is found superior to the older interval therapy, then, next after the martyrs to gout, I shall be the most delighted

THE INSULIN MYTH

SIR,—It is with commendable courage that Dr Bourne (Nov 7) has exposed the myth. Yet like all iconoclasts he must be prepared to be attacked in turn Loins will undoubtedly be girded It therefore behoves us, who feel that he has said something which has long required saying to come to his defence

The fallacy of insulin therapy lies not in the treatment itself, but in the diagnosis of schizophrenia. Bleuler's concept of schizophrenia was a protest against the prognostic pessimism implied by Kraepelin's dementia præcox Bleuler included in his schizophrenic group many conditions which have never been shown satisfactorily to have any real ætiological relation to dementia præcox or, as it is usual to term it nowadays "process schizophrenia"

Within seven years of the origin of the concept of schizophrenia its unsatisfactory nature became apparent Anyone who wishes to verify this can turn to the *American Journal of Insanity* for 1918—to a paper [1] by Phyllis Greenacre which is as apposite today as when it was written One would have thought that the many excellent studies which have appeared since then such as those of Kasanin and Langfeldt, would by now have had some penetrating effect. These studies, describing "schizo affective" and "schizophreniform" states have shown that a fairly clear distinction can be made between "process" and "benign" schizophrenia although borderline cases can certainly occur

I have myself described these benign schizophrenias as "atypical depressions" and I set out the reasons for doing so [2] The 16 cases in that group which would certainly have been diagnosed as "schizophrenia" by other psychiatrists and indeed in some cases were, have now been followed up over a period of five years They were all treated symptomatically or with E.C.T in no case was insulin-coma therapy administered It is hoped to publish this follow up study in the near future, but it can be said of the 10 surviving cases in which full information has been obtained 5 have remained completely well since their discharge, and 5 have relapsed but responded to further courses of E C T Some of these cases have had repeated episodes of this kind over periods as long as twenty years, but the essential feature is that they do not dement and they are absolutely normal in between 2 of the younger patients having their first attack, and who responded to E C T have both remained well and have successfully undertaken training courses for professional careers since their discharge from hospital

Insulin coma is a prolonged and dangerous form of therapy Its continued use would only be justified if it was shown conclusively to have a curative or at least an arresting *effect in true schizophrenic conditions.* This has never been scientifically proved, and indeed all the evidence is that the cures in insulin-coma therapy are in those very cases which have within themselves the potentiality for cure or which respond to physically less harmful forms of treatment, such as E C T

It is obvious that clear clinical thinking in psychiatry especially on this point, is long overdue if we are to appreciate fully the value of the different forms of physical treatment which are now so freely used Schizophrenia is not a disease but a congeries of different conditions, the natural history of these conditions must be studied more closely if we are to see which are benign and which are malignant. In exposing the insulin myth, Dr Bourne has indicated the way

[2] Jarvie H. F *J ment Sci.* 1950 96, 203

Department of Neurology,
Radcliffe Infirmary,
Oxford
HUGH F JARVIE

SIR,—Dr Bourne has shown that, by selecting one kind of evidence and disregarding another, he can convincingly prove to himself what he has set out to prove

I have applied hypoglycæmic treatment to 1300 schizophrenic patients of both sexes, and E C T to many hundreds of others, in the treatment centre at Springfield Hospital since 1940 (I am excluding schizophrenics treated at other hospitals since 1936) This group of 1300 patients constitutes a homogeneous series as regards diagnosis, prognostic criteria, and assessment of degrees of recovery It has also been subjected to a "follow up" over a long period

The course of treatment I apply consists of 50–60 deep comas in each case, divided into six weekly coma doses E C T has been given in most cases in conjunction with insulin and has proved its value But E C T alone is without much effect, any improvement noted being transitory, no matter how many times or at what intervals E C T was given

Obviously it is essential to compare comparables only, and it is clinically and statistically quite unsound to add the results of such treatment, as applied in many hospitals, to the results of "diluted" hypoglycæmic treatment—as with subcomas, short comas, reduced number of comas, and so on—and to draw conclusions from this Many accounts disregard this point

To administer E C T alone to a schizophrenic, if there is no contra-indication to insulin, is to deprive the patient of a reasonable prospect of recovery

In my series every precaution was taken, in assessing results, that my judgment should not be disturbed by expectations gloomy or optimistic My experience has revealed to me that although hypoglycæmic treatment, combined with some E C T and followed by psychological rehabilitation, is far from the last word in the therapy of schizophrenia, it is at present the best we can offer Because of the unsatisfactory state of our concept and knowledge of schizophrenic illness in all its forms, all physical treatments are applied faute de mieux

Although reports and reviews of hypoglycæmic treatment and E C T in schizophrenia abound in this country and abroad, I support Dr Sandison's suggestion (Nov 21) that a committee of the R M P A should be instituted to review hypoglycæmic treatment in our hospitals

London W 1
CHARLES FRIEDMAN

SIR,—Certainly at least one side of Dr Bourne's contention that insulin treatment of schizophrenia has only mythological efficacy is belied by the observation every psychiatrist will have made occasionally As soon as the patient who may have been quite refractory to any other treatment starts his comas, he loses some of his symptoms That this is not merely due to the increased attention, to suggestive factors working on patient or therapist, or to chance, is clear to anyone who sees as often as I do the changes for the better in patients who, for one reason or another, have gone through a more than usually protracted period during which only sopor was attained This applies in my experience equally to patients who have had previous E C T, concomitant E C T, or none at all

Whiterton Hospital
co Durham
D J SALFIELD

PROLONGED APNŒA FOLLOWING SUCCINYLDICHOLINE

SIR,—Undoubtedly, all cases of sensitivity t succinyldicholine should be published, especially wh they are due to rare conditions such as the greatly reduced pseudocholinesterase level in a normal subje described by Dr Forbat and his colleagues (Nov 21 However, I criticise the dose of 50 mg of 'Scoline for a cystoscopy and examination under anæsthe which in fact was completed in five minutes. Seve published cases of inconvenient prolongation of eff have followed administration of 50–100 mg, and it unfortunate that such doses are still recommended f similar procedures, and are widely quoted by the man facturers Smaller doses, which can always be supple mented when necessary, would avoid such unexpe incidents

The individual variations in response to the drug a great. In a series of 350 abdominal operations, using th continuous drip technique for relaxation, I have fou that the average maintenance dose of succinyldichol is 300 mg per hour. However, doses as high as 1100 m per hour have been needed on occasions, and in cert patients with subnormal pseudocholinesterase lev 60 mg per hour was adequate for full relaxation The fore, the administration of such unnecessarily lar initial doses as those recommended cannot be justified

The wide variations in response, associated with th occurrence of abnormal pseudocholinesterase leve does not contra-indicate the use of succinyldicholi provided the administration is on a rational bas In practice, the flexible controlled relaxation that can produce is invaluable, and it would be regrettab if the publication of incidents of avoidable overdo should retard a great advance in anæsthesia. T use of test doses in many cases reported would hav reduced them to academic and biochemical, rather th clinical, significance

R J HAMER HODGES

VISITING CHILDREN IN HOSPITAL

SIR,—There seems to be a lamentable tendency the days to regard children as so many bundles of psycho logical problems—a tendency followed, no doubt with excellent intentions, by your annotation Having don some children's nursing I have seen the problem fro both sides, and my sympathies lie with the children an their parents by all means let us have visiting of th children as often as possible—preferably daily Let u not, however, search too hard for complex psychologica reasons for visiting, nor attribute to lack of it too man undesirable childish habits One does not have to be psychologist to know that a child wants and needs it mother—an unnatural child of an unnatural mother th does not! But a good many mothers who have suffere embarrassing moments from childish outspokenness an inability to dissemble feelings may ask how it is prov that a child inwardly pining and miserable is "capab of interest and animation on the surface" On the who the comments of the young East-enders leave one in litt doubt as to their feelings on entering, staying in, an leaving, hospital Your annotation counsels the docto opposing the daily visiting of children against trustin their own observations "which investigation has prov to be misleading" May we know whose observation ha shown "bed wetting, temper tantrums, delinquency an the like" to be attributable to a stay in hospital, an what steps were taken to ensure that *such* observation not misleading too? Does boarding school produ similar symptoms, demanding daily visiting also?

There are plenty of excellent reasons for allowin children to see their parents every day in hospital, with plea for discretion where necessary, on the part of bot hospital staff and parents, not the least reason being the growth of confidence in the hospital on the parent's part and increased experience and understanding of the parents on the part of the nursing staff It is not needful to create added complexities in the unfortunate children

IDENTIFICATION OF PILLS

SIR,—A year ago Dr Russell and Dr Thorne[1] described a tablet-identification box, and their article was followed by some correspondence on this subject

It seemed to me then that much uncertainty could be removed—both in the treatment of overdosage and in general practice—if we all got into the habit of putting the name and dosage of each drug on its container I started to write this in full under the Sig part of each prescription until I discovered from a friendly chemist that all one need do was to write *Nomen proprium* (shortened to Nom. prop) with the instructions to be put on the container The dispenser then puts the description and dosage on the packet

I have now been doing this for some months and find it a great help, both to my own brain which does not have to recall whether the white tablets for Mrs. Jones's breathlessness are phenobarbitone, digoxin, aminophylline, ephedrine, or anything else and to my partners who no longer have to recall which is my favourite sedative or *carminative when it is demanded as a repeat* by one of my patients.

I may say that, in our firm, opinions are strongly divided one colleague is enthusiastic and has written to our local hospitals asking that their dispensers do the same for consultants occasionally alter treatments in patients who attend over long periods, without our being aware of the change Another colleague feels that knowing exactly what they are given may make the more sophisticated patients introspective or distrustful—that a little faith helps a lot—or that they may tend to prescribe for themselves.

Totton, Southampton EOIN L. MCQUITTY

SALMONELLÆ IN TORTOISES

SIR,—Boycott et al[2] state in their article on salmonella in tortoises, mentioned in your annotation of Aug 15 that 'no-one to our knowledge has examined the fæcal flora of *Test græca* in its native haunts.'

We started such an investigation in March 1953 going back to a casual observation in 1930 which could not at that time be followed up systematically Our findings will be published in due course. The following results have so far been obtained

A high proportion of free-living healthy tortoises of the species *Test græca* (syn. *ibera*) in *Palestine are salmonella* carriers, not so rarely harbouring in their bowels more than one type It may be assumed that, once naturally infected, a tortoise remains a carrier of salmonellæ for the rest of its very long life. It is known that *Test græca*—the swine among the reptiles, as it has been called—is an omnivorous animal feeding even on mammal excrements. Therefore if Boycott et al. make the suggestion that 'the high carrier rate of salmonella in imported tortoises may be due to infection in transit," they are right in being 'not convinced that this is the entire explanation.' As for the rest we can confirm that the salmonellæ these tortoises are excreting belong to the new types or are types not hitherto described.

Moreover we do not know if human infections have been caused by keeping tortoises as pets. Nevertheless the warning of Boycott et al regarding the risk to children should be taken to heart, all the more so because, contrary to the experience of these authors, we found that production of fæces was not so infrequent and that they were soft and relatively voluminous if fresh vegetables were given as food

WILLY HIRSCH
RAJA SAPIRO HIRSCH

CORONARY HEART DISEASE AND PHYSICAL ACTIVITY OF WORK

SIR,—Dr Morris and his collaborators have put forward a very interesting hypothesis and have been to great pains, with I think some success, to show that the excess mortality amongst sedentary workers is not due to their social circumstances—i e their income, which implies the amount of money available to spend on food, particularly the most expensive article of diet fat.

That this was a major hazard to surmount is obvious in that most work that requires physical activity is paid at a lower rate than work which can be done from a desk I trust that their exposition will not draw attention from the fact that the main factor in the pathogenesis of atherosclerosis and hence coronary disease is a disturbance of cholesterol metabolism and in case your readers have not yet read it, I would like to draw attention to a recent article by Ancel Keys[1] which is a fascinating addition to the vast literature already available on this matter Keys states that American males aged 40–65 have a higher mortality rate than males in any other major country excepting only Japan and Portugal This high mortality was found to be due entirely to *heart-disease mainly coronary heart-disease Americans* according to Keys have the highest fat consumption in the world and the cholesterol blood pictures in these men are in line with this argument Keys also mentions this fact of physical activity in the ætiology

I have always felt that there is one other factor involved in the deposition of cholesterol in the elastic arteries—first suggested by Thoma nearly sixty years ago—and that is a relative slowing of the blood-stream When the lipophage was incriminated by Leary I brought forward evidence,[2] to show that by the application of simple physical data it could be shown that this deposition occurred in elastic arteries where the blood velocity was slowest The lipophage theory is out of date now but I wonder if similar considerations could not apply to the modern lipoprotein macromolecules or the chylomicrons. If this is the case may we assume that there is a faster blood flow in the main coronary arteries of those whose work involves physical labour and hence their relative immunity to cholesterol deposition?

Ilford. I GORDON

SIR,—I am most interested in the statistical analysis by Dr Morris and his colleagues, and in your leading article last week *In a recent article*[3] *I anticipated* your conclusions that the increased incidence of coronary heart-disease in general practitioners is due to lack of exercise and sedentary conditions and that the higher incidence in the professional and upper classes may be *also due to the richer diet in these classes.*

When Morris et al[4] in their study of 6000 records of medical practitioners showed that the incidence of coronary-artery disease was greater in general practitioners than in specialists and other doctors, I came to the conclusion that this was due to the lack of exercise owing to the general practitioner's hours of work most his time being spent sitting at his desk doing his argery, or sitting at the wheel of his car visiting patients Having practised both as a general practitioner and as a specialist for many years, I could not accept the view that the mental stress of a specialist today was any less than that of a general practitioner

[3] *Med Pr* 1953 230 533
[4] Morris, J N Heady J A., Barley R. G *Brit. med J* 1952 i, 503.

As you point out, there are two problems to consider—the causes of the basic atheroma, and the causes that lead to occlusion Recent work, particularly by Gofman,[5] has shown that atheroma is related in some way to lipoid metabolism, and according to Gofman the recurrence-rate of myocardial infarction is significantly lessened in patients with established coronary artery disease whose level of lipoproteins has been reduced by estriction of dietery fat Genetic influences, however, must play an important part, and in some cases are probably more important than habits of life and work, for how otherwise can we explain the advanced degenerative atheromatous lesions found in the coronary arteries at an early age, which I found to exist in a review of 100 cases of coronary occlusion in young adults.[6] Most of these young patients would have fallen into the Registrar-General's social classes IV or V There was no indication that special stress had been a sustained experience

Nevertheless, as I have pointed out,[3] even if an individual is hereditarily predisposed to atheroma the incidence of could be made by the general practitioner

" A useful contribution to the lowering of the incidence of coronary occlusion could be made by the general practitioner Patients who have a family history of coronary disease or hypertension and particularly if they are of the coronary physique (mesomorphic type) should be advised to regulate their diet particularly as regards the lipoids so as to avoid overweight and obesity If the occupation is of a sedentary nature regular exercise should be taken. The practitioner himself should also note the saying 'Physician, heal thyself' "

MAURICE NEWMAN

Blackpool.

ARTERIAL TRANSFUSION

SIR,—I was delighted to read Dr Allan Brown's experiences (Oct. 10) with arterial transfusion and bleeding in neurosurgery I have seen how smoothly and efficiently this can be performed with a closed circuit apparatus as designed and used by Dr Peter Mortimer of the Bristol Neurosurgical Unit[7]

I am prompted to report a case in which arterial transfusion was used for resuscitation, as the response dramatic, though not maintained because of con- ed hæmorrhage

A man of 53, who had been run over by a bus, was seen 6 30 P M on Oct 13, 1953 He was unconscious and verely shocked with a fractured pelvis, open fractures of e right leg and left ankle, right mid thigh and supra ondylar fractures, and a possible fracture of the base of the skull The muscles of the right calf were extensively denuded. Resuscitation in the ward with dextran and blood intravenously produced temporary improvement The maximum blood pressure was 110/75 mm Hg, and the pulse-rate was 84 at 7 P.M There was no further improvement

He was given atropine gr $^1/_{100}$ and was taken to the anæsthetic room in his bed at 9 45 P.M A rapid decline was noted The intravenous blood transfusion would not run Respiration was slow and periodic, there was extreme pallor and a relaxed jaw A laryngoscope was used to expose the relaxed ds which were sprayed with 2% amethocaine A cuffed be was passed easily Assisted respiraton with oxygen ought some colour back and a faint radial pulse The atient was transferred from the bed to the operating table hich was in a 20° Trendelenburg position.

The surgeon cut down on the right femoral artery, and transfusion by this route was started at 10 P.M. Four pints of blood was given in forty minutes. The respiration rate improved dramatically to 30 or 40 per min, and the systolic pressure rose to 80 mm The peripheral circulation of ears and nail beds improved and the intravenous transfusion began to run well An anæsthetic consisting of ga oxygen (2:1), pethidine, and 'Scoline' (50 mg of was given. A right mid-thigh amputation was pe A suprapubic incision revealed extensive extrape bleeding and blood-clot, a ruptured urethra, and vasated urine The bladder was drained. The bleeding could not be arrested and packs were inserted

At midnight the patient was returned to the ward left the theatre with a systolic pressure of 70 mm tracheal oxygen was continued The blood pressure re at about this level during the night The pulse-rate 120, and the lungs were dry, but he deteriorated and at 6.15 A.M. The total amount of blood given was pints, and of dextran six pints.

At necropsy extraperitoneal extravasated blood from pelvis had extended to the lower poles of the kidneys was a fracture in the base of the skull and a small su hæmatoma. Although these injuries were "not comp with life," resuscitation did enable the amputation exploration of pelvis to be performed.

Guy's Hospital London, S E 1

REPUTATION OF SPINAL ANALGESIA

SIR,—At the hearing described in your issue of No (p 1000) a professor of neurosurgery is reported have stated that an anæsthetist should know tha normal dose of spinal anæsthetic is dangerous involves the risk of permanent injury In the report, a distinguished neurologist asserts that it is time that the whole problem of the complication spinal anæsthesia was re-examined by the medical fession While venturing to question the accura the first opinion as reported, I suggest that nothin good can come of the second suggestion B re-examination must not be prejudged

The neurologist, medical and surgical, sees very rare bad result, just as the laryngologist uncommon granuloma of the vocal cord follow tracheal intubation, the dental surgeon the r a tooth caused by a laryngoscope, the chest physician s unusual severe chest complication following a surgical eration. Is the anaesthetist to be precluded from using s customary methods of anaesthesia because of the rare mplication, when tens of thousands of patients show such complications at all ?

---

[5] Gofman, J W *Wis med. J* 1952 51 7 087
[6] *Lancet* 1951 i 1045
[7] Mortimer P L. F *Anæsthesia*, 1951, 6, 125

[1] Harvey William Circulation of the Blood and o
Trans. Willis. London, 1907

It is an unfortunate fact that anaesthesia and analgesia ust always be purchased at a price and every care ust be taken to see that this is the smallest one possible ut, in spite of the greatest care and attention to detail casionally it turns out to be high whichever method technique is used

At the present time most surgeons and anaesthetists ould agree that the indications for spinal analgesia ave greatly decreased since the use of muscle relaxants came general, but I submit that the method when roperly indicated—e.g., in certain obstetric or pelvic perations—and when skilfully carried out, may be of finite benefit to the patient and should not therefore e lightly discarded

Westcliff-on-Sea. J ALFRED LEE

THE ASCENT OF EVEREST

SIR,—The annotation entitled The Ascent of Everest your issue of Nov 14 contains the statement that the 1953 Expedition differed from its predecessors having a physiologist who was not a mountaineer

This statement is incorrect. The physiologist had fact as much mountaineering experience as most of e climbers, but one cannot do physiology and climb well. The scientific contribution to the success of e expedition was made possible by the survey of hysiological problems carried out the previous year n Cho Oyu. This could not have been done by a hysiologist who was not a mountaineer

SUBCLINICAL POLIOMYELITIS INFECTIONS

SIR,—Dr Bradley (Nov 28) is to be congratulated n maintaining his concept of ' narrow stream spread f poliomyelitis in the face of overwhelming torrents of vidence to the contrary

Dr Bradley notes that ' examples of ' narrow stream ' pread have now been recorded by many field workers. ' have not been able to discover any field studies which fter critical examination, alter my belief that polio myelitis virus is *widely* disseminated. The best example of hat Dr Bradley calls limited selective distribution " f virus is probably that of Brown et al.[1] While I do ot wish to embark on a criticism of their paper it eems worth pointing out that the strains of virus in he outbreak which they studied were of low pathogenicity and a single monkey might not have demonstrated virus in a single specimen Tests by a more ensitive technique—e.g that used by Melnick and Ledinko[2]—might well have shown a more widespread distribution of virus Perhaps more important is the point that in studies which have suggested a limited selective distribution there may have been little virus in evidence at the time the samples were taken for virus isolation A serological technique such as that employed by Melnick and Ledinko overcomes this difficulty

It would seem to be short-sighted to base any conclusion of possible control methods on a single study or even a single method of approach The concept of a wide dissemination of virus as opposed to a narrow stream, is reached from epidemiological, as well as serological studies and virus isolations. At the same time, it should be stressed that the much quoted 100 : 1 or 1000 1 ratio of non paralytic to paralytic infections is a cumulative estimate and does not necessarily represent the finding in any one outbreak This ratio probably varies greatly with a number of factors—e g the strain of the virus and also perhaps the habits of the people With regard to the latter it is hoped that Dr Bradley's ' general measures for controlling ' the spread of poliomyelitis will provide some information Control measures have not in the past been employed because presumably, most people are more than doubtful that they would be successful Nevertheless, I think I would share with you Sir, surprise and delight if control methods based on the ' new evidence ' to which Dr Bradley refers are attended with success

London N W 7 G W A DICK

LACTIC ACID IN THE TREATMENT OF OSTEO ARTHRITIS

SIR,—I entirely agree with the criticism of Dr Lawrence's conclusions made by Dr Vergette in your issue of Nov 28

Though I have not found that the intra-articular injection of an acid solution arrests the disease of osteo arthritis, it certainly gives remarkable relief As a result of this Dr Vergette was almost overwhelmed by the large number of patients to whom he gave fortnightly injections The object of this letter is to suggest to Dr Vergette the use of acid potassium phosphate (with procaine) rather than procaine lactic acid Injections have to be given less frequently A fortnight's interval after the first and then injections every four or five weeks will in most cases, maintain the relief

London, W 1 H WARREN CROWE

Parliament

New Industrial Diseases Benefits

THE House of Commons gave a second reading on Nov 23 to the Industrial Diseases (Benefit) Bill. Mr OSBERT PEAKE Minister of Pensions and National Insurance, explained that its main purpose was to extend the provisions of the Pneumoconiosis and Byssinosis Benefit Act, 1951, to cases of partial disablement. The 1951 Act provided compensation for cases of total incapacity or death in people with pneumoconiosis or byssinosis who failed to get benefit or compensation either under the Workmen's Compensation Acts or the Industrial Injuries Scheme which supplanted them in 1948 Since the 1951 Act came into force in March, 1952 some 6000 medical examinations had been made. In the first few weeks the panels had dealt with about 250 cases weekly but the rate had now fallen to about 50 So far, 3300 awards had been made for total disablement and 840 for death. It had been generally agreed that the 1951 Act should, if possible, be extended to cover corresponding cases of partial incapacity, but a formidable difficulty was the immense burden which might be thrown on the medical panels both by a flood of original claims and by the possibility that, as disablement progressed re-examination and re-assessment would be needed The present Bill proposed a flat rate of payment equal to half the rate payable under the 1951 Act for total disablement. This would apply to all cases of partial incapacity of a degree sufficient to attract a continuing payment under the old Workmen's Compensation Acts. This meant that a single medical examination would suffice at any rate until the time when partial incapacity became total Even with this rough and ready method the new scheme might entail nearly as many extra medical examinations as the panels carried out in a single year under the Industrial Injuries Scheme. Clearly these examinations would have to be spread out over a fairly long period, but some people would qualify right away

The reason why the title of the Bill was not the same as that of the 1951 Act, Mr Peake explained was that the Trades Union Congress had brought before the inistry some cases of cancer, including mule-spinner's ncer, and cancers caused by X rays or radioactive bstances, which developed slowly and might exceed he time laid down for making a claim under the Work-nen's Compensation Act, 1925 A general power was being taken in the new Bill to make a scheme for cases of late development. The cost of the proposals embodied in the Bill in a full year were estimated to impose a charge on the Industrial Injuries Fund of £750,000 for pneumoconiosis, and perhaps £50,000 to £60,000 for other diseases.

Clean Food Bill

In the House of Lords on Nov 24, Viscount WOOLTON, Chancellor of the Duchy of Lancaster, moved the second reading of the Food and Drugs Amendment Bill,[1] which he hoped would be known popularly as the Clean Food Bill Lord Woolton said that the 1938 Act, useful as it was, no longer protected the public from either the carelessness or the perfidy of human beings. Since the war the habit of "eating out" had also grown and now extended over a wide range of people and places and prices. There had also been a great increase in the use of food prepared in factories and in the variety of processes of food manufacture. The scientist had become an important factor in food manufacture in recent years and had added much to the convenience and pleasures of life But all the contributions of science were not clear gain In any trade there were some who were careless, some incompetent, and some not too scrupulous. The present laws on adulteration came from a cruder age when the treacherous trader mixed alum with his flour and sand with his brown sugar In our more inventive and complex age, it had become the more necessary to protect the public from those who either from ignorance or greed endangered the public health. The Government were satisfied of the need to regulate these matters and to preserve a balance between what was good in science and what were the dangers The present law had proved particularly inadequate in dealing with chronic toxicity, and the Bill laid down that the cumulative effect of additions or subtractions of ingredients or processes must be taken into account.

But when all was done, Lord Woolton continued, much remained in the hands of the individual trader The individual consumer must enforce higher standards by making more fuss when he met dangerous or disgusting practices

The parts of the Bill which appealed to Lord WEBB-JOHNSON were those designed to deal with misleading labels and advertisements, and those which regulated the addition of specified chemicals It was true that the ublic themselves could do much to impose the adoption f cleanly methods on those who served food But the ublic were often not particularly well informed on the orrect way of handling food, and he hoped that every encouragement would be given to voluntary associations, such as the Order of St John, to extend their courses of instruction on food matters

Lord HADEN-GUEST hoped that the many regulations which would be required by the Bill would be written in plain English so that their purpose would be abundantly clear to those who were to carry out the work of inspection and to keep clean places where food is sold

Lord SEMPILL held that the Bill did not give the Ministers sufficient power to prohibit the use of substances or processes which might have a deleterious effect on health Eminent biologists and medical men had affirmed that the main reason for poor health in this country was the number of toxic elements in food He believed it to be vitally important that the food on our tables should be the natural products, free from the adding and extracting ministrations of the food chemists, and treated with great discretion by the refrigerating and processing technicians

Lord BLEDISLOE said that dispensing chemists were apt to paste their own label over the manufacturers' label when they were dispensing a proprietary preparation n a doctor s prescription This concealed not only the name of the drug but also the formula of its composition Lord WOOLTON thought this practice would be prohibited under the Bill

Drug-supplies for the East

In an adjournment debate on Nov 30, Mr HEATH AMORY, Minister of State for the Board of Tr some drugs, such announced that the controls on some sulphonamides, antibiotics, anti-malarials, and sulphonamides be lifted at the end of this year

QUESTION TIME

Sale of Condemned Meat

Replying to Mr BARNETT JANNER, Major GWILY GEORGE, Minister of Food, said that disposals of con meat and offal by public auction began on Aug 1, 19 during August approximately 1100 tons were sold in

Mr. JANNER In view of the large quantities which are being sold, will the Minister take further cautions than those indicated by him hitherto and see that meat does not reach places where it will be used for h consumption ? Does he realise that the very high p being paid indicate that it is being so used ?—Major GEORGE Under the new conditions of sales certain pr have to be gone through before the meat can be sold furthermore, under the new Food and Drugs Bill gre powers are taken to safeguard the position He hope introduce the new conditions of sale in time for tha auctions in December.

Sodium Fluoride and Dental Decay

Mr. WILLIAM ROSS asked the Secretary of State for Scot in which areas an effort was being made to reduce den decay by the application of solutions of sodium fluo Mr JAMES STUART replied Work of this kind has carried out among school-children in Dundee, Edinburgh, an Fife

Motor-cyclists and Crash-helmets

Mr R W SORENSEN asked the Minister of Transport and Civil Aviation what information he had demonstrating protective value of crash helmets to motor cyclists, whether there was a supply of these helmets sufficient for motor cyclists.—Mr HUGH MOLSON replied, Medical shows that the wearing of the best type of helmet gre reduces the likelihood of fracture of the skull in accidents makes head injuries generally less severe, and sample of taken before crash helmets were common in civilian indicated that the incidence of head injuries in motor accidents was over 50% among civilian riders but only abo 27% among Army riders wearing crash helmets I underst that supplies of crash helmets appear to be keeping pace wi the present demand.

Hertford British Hospital, Paris

Replying to a question, Mr A D DODDS PARKER, Jo Under secretary of State for Foreign Affairs, said that hospital had been shut completely since the summer of 195 In 1951 which was the last complete year in which all departments of the hospital were open and in use, the expenditure on maintenance was 49½ million francs. Dur that year fees paid by patients amounted to 17½ mill francs and income from investments was 4½ million The hospital s total income from all sources was therefo 22½ million francs, leaving an excess of expenditure ov income of 27 million francs (£27,300 approximately) Volun tary gifts during the year amounted to 15½ million francs and the net deficit was therefore 11½ million francs (£11,600 approximately) In 1950 when the cost of maintaining the hospital was only 42 million francs—i e, over 7 million fran less than in 1951—the excess of expenditure over income 18 million francs which was reduced by voluntary gifts subscriptions, amounting to 16 million francs, to a net defi of 2½ million francs (£2,400 approximately)

Tuberculosis Hospitals Waiting-lists

Replying to Brigadier MEDLICOTT, Mr IAIN MACL Minister of Health, said the numbers of patients suffering tuberculosis on the waiting lists for admission to hospita the end of 1950 1951, and 1952, respectively, were 9378, and 6126

Teaching Hospitals

Sir WALDRON SMITHERS asked the Minister of Health changes were contemplated in the policy of administra the teaching hospitals —Mr MACLEOD replied at present

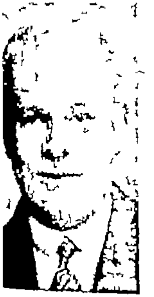
Obituary

BASIL HUGHES

D.S.O., M.A., M.B. Camb., B.Sc. Lond., F.R.C.S.

Mr Hughes, who died in London on Nov. 21 at the e of 75, will be remembered in the North for his work surgeon to the Bradford Municipal General Hospital d by colleagues elsewhere for his work in France and lonika in the 1914–18 war.

He was the son of Captain John Hughes, R.N., who er became a mathematical scholar of St. Catharine's College, Cambridge. From Eastman's R.N. Academy he went to Selwyn College, Cambridge. Perhaps influenced by his father's taste for mathematics, after he took his degree in 1907—he was well up in the list of wranglers—he was for a short time mathematics master in a Shropshire school. He then took up the study of veterinary surgery, but the interest thus aroused in anatomy and physiology made him change to medicine, and he entered King's College Hospital with a scholarship. After a brilliant career as a student he qualified in 1909 and was appointed resident surgical officer at The Hospital for Sick hildren, Great Ormond Street. In 1911 he took the R.C.S. and the same year he became resident surgical ficer at the Bradford Royal Infirmary. Two years later e set up as a consulting surgeon in Bradford.



[Walter Scott

At the outbreak of war in 1914 he was called up at nce as a Territorial officer and after six months in ngland went as a regimental medical officer to France, here most of his time was spent in the front line or e nearest clearing-station. The saga of these years n be read between the lines of his *War Surgery from ying-line to Base*. H. S. B., his collaborator in this ok, recalls the stir and controversy engendered by ughes's work and personality in the Army hospitals in lonika in 1916:

"He came to Salonika from France already endowed ith a unique experience of war surgery in the front line en in the trenches. While there he had made a searching actical study of the technique of irrigation of wounds troduced by Carrel and Dakin, and he had finally discarded e older antiseptic methods in which he had been trained n favour of the new. In Salonika, where no-one had yet actised these methods, he naturally encountered a good al of opposition, not unmixed with professional jealousies ut despite all difficulties his unit in the 28th General ospital soon became a show place for war surgery.

"It must be difficult for younger surgeons to visualise the eatment of war wounds, especially those complicated by s-gangrene and profound shock, without the aid of chemotherapy, antibiotics, or blood transfusion. The patient, after surgical débridement, had to rely solely upon his own owers of recuperation, aided at this time by continuous rigation of the septic surfaces with hypochlorite solution. The first impression one had of Hughes's wards was of a rest of irrigating stands supporting automatic flushing pparatus with rubber tubes stretching out in all directions o the patients in adjoining beds. It was most exhausting ork, not only for Hughes himself but for all his medical nd nursing staff, but it was carried on with great enthusiasm hen much improved results began to be apparent. There ust be many soldiers of that time who were saved from mputation by the skilled and devoted work of Hughes and is teams in Salonika."

Hughes's long sound basic training, combined with his war experiences, turned him into a brilliant surgeon, and his reputation was enhanced by a charming manner and winning ile. He was, however, an intense individualist and could not work long with anyone whose views differed even slightly from his own. There would come a sudden revulsion of feeling as if his Celtic temperament had been jarred, and then an apparently inexplicable coldness and usually final estrangement. So he tended to become a somewhat lonesome figure, pursuing his own brilliantly successful career almost alone.

He lived a long and strenuous life with single-minded devotion to the task upon which his heart was set. That was to give his patients equally, and with right good will, the highest skill which surgery could provide—whether they were Tommies in the trenches, poor children in a Bradford Hospital, or wealthy private patients—and he followed his gleam with zest and fervour and joyful satisfaction.

For his war services the Order of St. Sava of Serbia was conferred on him, and in 1918 he was appointed D.S.O.

After the war Hughes returned to Bradford, where he was appointed assistant surgeon to the Children's Hospital and later to the Royal Infirmary. About this time St. Luke's Hospital was being transformed into one of the great municipal general hospitals of the country, and in 1922 Hughes was appointed one of its first consultant surgeons with 100 beds. Here he found full scope for his operative ability in general surgery.

B. H. S., who was his colleague in this venture, still remembers his first meeting with Hughes soon after he came to Bradford.

"A short lithe figure—he had played in the forward line of the Stoke City A.F.C.—surmounted by a large well shaped head, shy cherubic features, and a philosopher's brow. But it was during our 18 years together at the Bradford Municipal General Hospital that I came to know and appreciate his work.

"He made the surgical side of the hospital known and respected throughout the West Riding and beyond. The hospital's success in its new rôle was largely based on his reputation. To see him operate was an æsthetic delight and a lesson to the ham handed. The theatre hushed as at a solemn rite, his sensitive hands moving delicately, smoothly, swiftly, purposefully through all stages of the operation. He was the first in the North to try out Avertin as a basal anæsthetic. During the latter half of our association he did most of his abdominal surgery under local and splanchnic analgesia. He brought new ideas from Vienna and Denmark on fractures and gastric surgery. His list at St. Luke's often included 15–20 operations. He was a man of restless activity and well-stored mind, and in his meagre spare time he found solace and pleasure in music, of which he was an informed lover and a fine executant on piano and organ."

During the second world war Hughes again did great work for wounded Servicemen and initiated and organised a special ward at St. Luke's for the prevention and treatment of shock. He was a fellow of the Association of Surgeons of Great Britain and Ireland and a founder member of the International College of Surgeons.

When he retired in 1945, he characteristically took up a completely different occupation with great enthusiasm and success. He became a farmer in Cornwall, installed the most up-to-date equipment on his farm, did all his own tractor work up to the age of 75, and lived a hard working country life away from all except local society, as self contained as ever. He became an enthusiast for completely natural home produced food, especially wholemeal bread. "My patients," he wrote to a friend, "are now the population of the soil," and he strove to produce the highest nutrients from the soil with the same enthusiasm as he had striven to help his patients.

Mr Hughes married in 1932, as his second wife, Miss Norah Blaney, the actress, and she survives him.

THOMAS WILLIAM LUMSDEN

M.D. Aberd.

Dr Lumsden, director of cancer research at the London Hospital from 1930 to 1942, died on Nov. 24 at the age of 78.

He was the son of the Rev. Edward Lumsden, of Midmar, Aberdeenshire, and he was educated at Aberdeen Grammar School. At the University of Aberdeen, where he graduated M.B. with honours in 1897, he was awarded the Fife Jamieson gold medal in anatomy, the Shepherd gold medal in surgery, and the Struthers gold medal in anatomy. In 1900 he settled in practice in Belgravia and the following year he took the degree of M.D. with commendation.

During his twenty five years in general practice he lived a comfortable and, to outward appearances, contented existence. But he was not really happy in ork. Even as a student he had been of an inquiring and as he did not find an outlet for this in general ce he turned his attention to laboratory research. Lister Institute was nearby and the head of the riological department in those days was Professor er Sir John—Ledingham who had been a fellow ent at the University of Aberdeen It was presum- through Ledingham that Lumsden obtained the oduction to Sir Charles Martin, director of the itute, which started him on a research career At t he gave only a part of his time to his investigations would look in at the Lister when going the round of patients, make an experiment, and then dash off ain to his practice Gradually he became more and ore absorbed in his laboratory work until he decided give up his practice and devote himself entirely to search, and in 1925 he became an honorary assistant the pathology department of the institute At first e was interested in the existence of supplementary espiratory centres, but soon cancer occupied all his attention, and in 1928 he moved to the London Hospital, where two years later he was appointed director of cancer research

With the outbreak of war and the dispersal of the London Hospital and its medical school over Essex and the adjoining parts of Middlesex and Hertfordshire, Lumsden was moved to Chase Farm Hospital at Enfield Here he was given laboratory space and the opportunity of putting the finishing touches to his researches with a view to writing up his work on anti-cancer sera. Towards the end of the war, this work accomplished, he retired from the London Hospital and went to live in Hertfordshire.

A former colleague writes "Like others before him, Lumsden was imbued with the idea of making an anti-cancer serum, and to this end he devoted himself with a fervour which was almost religious. He imagined at it might be possible one day to treat malignant dis- se by means of antisera it was as simple as that, saw his problem clearly in black and white and he t himself to solve it with the optimism born o nthusiasm What did he achieve in all the years he evoted to cancer research? It is sad to think that so nuch thought and skilful work should have left so nsubstantial a record, though one hastens to say that this was hardly his fault. He had his critics it is true, but it would be the greatest mistake lightly to dismiss Lumsden and his work. He was single-minded in his enthusiasm for his research and he believed so strongly in himself and his mission that he was prepared in middle age to abandon the security and affluence of a well-established practice for a research post without any assured future Had he been better trained in the scientific method and had he been a little more amenable to guidance, he might well have left a better record of achievement

"Lumsden was a difficult man to know At work he was on the friendliest terms with his colleagues, but none was allowed to intrude into his private life It was known that he lived in Chelsea, but where exactly was not recorded. One of his recreations was drawing, for a time he was a member of a life class in Chelsea and his work showed that he was not without talent. He enjoyed orchestral music, particularly Wagner But it was at work in his laboratory that he undoubtedly found his greatest happiness"

In our obituary of Mr T G Stevens (Nov 21) we stated incorrectly that his wife survived him Mrs Stevens died on April 2 of this year

---

Notes and News

A GREAT PHYSIOLOGIST

Torsten Thunberg was almost 80 when he died on Dec 1952, after a short illness initiated by a fractured femu was actively engaged in research until the very end his last paper—a review of citric-acid metabolism—was lished in *Physiological Reviews* a month after his de Thunberg will always be remembered for his work on biolo oxidations, which he pictured as proceeding by the enzym activation and subsequent transference of 2 hydrogen from the molecule undergoing oxidation to some hydrogen acceptor which might be another cellular compo or oxygen itself, or, for experimental purposes, methy blue. This conception enabled biochemists to visualis explore the controlled oxidations which character cells far better than the idea of an "active" or acti oxygen could ever have done, and was the inspiration of of the great work on cellular oxidations carried out in bridge between the two world wars. Thunberg was o those men whose genius overcame physical limitations department was very small and so limited in numbers th was never able to build up a great school Neverthe lived to see the creation of one of his heart's desires—the physiological institute at Lund, which is devoted very to research

Mural tablets are dull things, and even bricks and offer scanty satisfaction to the creative mind Workers a new institute, therefore, decided to dedicate a supplem the 30th volume of *Acta Physiologica Scandinavica* to t great predecessor, and the book contains their tributes memory and inspiration in the shape of nineteen or papers on various aspects of physiology

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issu following new supplementary list of approved names

Approved name	*Other names*
Amodiaquine	7-Chloro-4-(3-diethylaminom 4 hydroxyanilino) quinoline Camoquin
Azovan Blue	Tetrasodium salt of 4 4′ bis[illegible] amino-8 hydroxy 2 4-di[illegible] naphthylazo] 3 3′ bitolyl Evans Blue.
Carbomycin	An antibiotic produced by [illegible] of *Streptomyces halstedii* Magnamycin.
Laudexium Methylsulphate	Decamethylene-1 10 bis 1-(3 4 dimethoxybenzyl)-1 2,3,4-tetra hydro-6 7 dimethoxy-2 isoquinolinium methylsulpha Laudolissin.
Meclozine	1-p-Chlorobenzhydryl 4-m-me benzylpiperazine. Ancolan is the dihydrochlorid

RESEARCH ON DELINQUENCY

As a rule an aura of youth and inexperience surrou second annual report, but this does not apply to the report[1] of the Institute for the Study and Treatm Delinquency which was incorporated last year This of course, is identical with the Institute for the Treatment of Delinquency which has been in action was founded by the late Dr E T Jensen in 193 Portman Clinic which he also founded now operate National Health Service under the ægis of the Pad Hospital Among the research projects sponsored institute are an inquiry into the part played by low in in the causation of delinquency, a statistical stud delinquent boys aged 7–17 seen at the Portman 1952–53, and a study of the effect of œstrogens offenders A joint committee of the institute and th League for Penal Reform has been set up to ma investigation of cases of cruelty to children, Commissioners have agreed to allow those senten the past year for offences involving cruelty to chi examined psychiatrically, and a concurrent stu made of the social, economic, and cultural ba the families in which the cruelty occurred

The institute conducts extension lecture co diploma in social studies, and for the new dipl logy, of the University of London, and also a and courses on delinquent and criminal behaviour for psychiatrists. It offers study courses for magistrates assists with the Home Office courses for probation officers in training and arranges lectures for prison officers A summer school is to be held next year at Oxford from Sept 18 to 25 on the Changing Attitude of Society to Criminal Responsibility The Paddington Hospital Group Management Committee have made two grants, each of £50, to the Portman Clinic, for the purchase of medical books. These are being added to the Jensen memorial library, and books have also been bought with a grant made by the trustees of Dr Jensen Among the publications of the institute are the *British Journal of Delinquency*, now in its fourth year, and a range of pamphlets on psychiatric and criminological subjects

---

[1] Annual Report 1952–53 Institute for the St ment of Delinquency, 8, Bourdon Street, Davies W 1

CARDS FOR CAUSES

The British Epilepsy Association have just notified us that this year they too, are selling Christmas cards and Christmas seals. The cards, which are sold at 5*s* 6*d* a dozen postage paid, carry a design by Hero of Father Christmas skating and at the same time juggling in a reckless manner with five stars. The seals bearing the candle design which is the emblem of the association, are sold at 1*s* for a sheet of 48 Both may be had from the association, 136, George Street, London, W 1

JAMES BRIDIE S DRAWINGS

The late Dr O H. Mavor (James Bridie) saw an exuberant and ludicrous world, and drew what he saw with genial gusto In his drawings of university personalities at present on exhibition in the print room of the Department of Fine Arts at Glasgow University he pulls the legs of the great men of yesterday and today mischievously and without malice The great Sir William Macewen quizzes a hapless medical superintendent remembering his name but failing exactly to recollect his face Sir Robert Muir in his laboratory disreputably dressed, flatly rejects the offer of a new coat from his immaculate assistant the future Professor Shaw Dunn. One surgeon is shown introducing martial law into his theatre A second receives from an urbane medical colleague an unwelcome lesson in medical deportment There are grotesque but wholly successful caricatures of the formidable Sir Donald MacAlister of Murdoch Cameron in a bathing suit, of a prognathous and discursive E P Cathcart and one can even see Graham Kerr dividing by binary fission.

FILMS AT LONDON MEDICAL EXHIBITION

More films but fewer new films than in previous years were shown at the London Medical Exhibition last month. A very good French film on *The Cyto-Diagnosis of Uterine Cancer* (25 minutes; sound colour) with an English commentary shows the collection of biopsy specimens and the staining and appearance of the sections by cinemicrography The two parts of the film are detailed and each part appears to have been intended for a different audience though the whole film will be appreciated by both clinicians and pathologists *Gastrectomy with Jejunal Replacement* (20 minutes sound colour) demonstrates the operation which was the subject of a Hunterian lecture by Mr F A. Henley earlier this year The procedure is clearly shown and readily understandable by gastric surgeons; but those less familiar with the Billroth operations will gain little from the film. On the other hand, no previous knowledge of the subject is necessary to understand and enjoy *Marrow Puncture* (33 minutes sound, colour) The technique of sternal puncture is shown both on a patient and on anatomical models and other sites suitable for marrow puncture are demonstrated The film ends with a farcical section in which the advice given in the film is ignored *Nalorphine* (10 minutes sound colour) deals with the response in dogs deeply narcotised with morphine and other opiates to the intravenous injection of the new drug A large clock is started as the injection is given and the dogs recover fully quite suddenly some ten to twenty seconds later *Pentothal Its Use in Intravenous Anaesthesia* (45 minutes sound colour) is disappointing. The film is in the form of a chat between an anæsthetist and a student mostly in the surgeon s room whilst they are awaiting the arrival of a patient for operation Periodically the anæsthetist s words are illustrated by scenes of an anæsthetist at work in the anæsthetic room and theatre, and at one stage the student is taken to another room to see a film of thiopentone being used. *Reduction of Surgical Hæmorrhage by Controlled Hypotension* (42 minutes; sound, colour) is a detailed exposition of the use of hexamethonium compounds during anæsthesia by means of demonstrations in the operating theatre animated diagrams, and puppets. A new American film *The Antibiotics and Terramycin* (22 minutes; sound, colour) deals rather superficially with the history of antibiotics and the use of terramycin The British *Venepuncture* (14 minutes sound colour) is designed for general practitioners and gives valuable hints on minimising trauma

MEDICAL SCHOOLS OF THE WORLD

THE World Health Organisation has published the first *World Directory of Medical Schools* (H.M. Stationery Office. 25*s*) which lists more than 500 medical teaching institutions distributed over 84 countries. With so much ground to cover the editors have wisely restricted the information they offer about each school to such salient facts as number of students and staff duration of studies, and fees. Even so there are not unexpectedly a number of blanks in their informative pages.

University of Oxford

On Nov 21 the degree of D M was conferred on P B S. Fowler

University of London

At a recent examination for the academic postgraduate diploma in psychological medicine G F Vaughan and Lorna Wheelan were successful.

Queen s University, Belfast

Dr R A. Womersley has been appointed to a lectureship in medicine

Royal College of Obstetricians and Gynæcologists

At a recent examination for the D OBST the following were successful:

Royal Medico-Psychological Association

At recent examinations for the D.P M. the following were successful:

J D C. Currie R. S. Ferguson, T E Hall I. E. J McLauchlan M. J Raymond, A. Smellie, Elizabeth Shoenberg

Harveian Society of London

The subject for the Buckston Browne prize (£100) for 1954 is to be Medical Problems of the Overweight Patient Essays should reach the hon. secretaries of the society, 11 Chandos Street, W 1 by Dec 1 1954

Royal Microscopical Society

At a meeting of this society on Wednesday Dec 16 at 5.30 P.M., at Tavistock House South, Tavistock Square London, W C 1, Mr R W G Wyckoff will speak on the Electron Microscopy of Viruses.

School Dentists

Speaking at Wakefield on Nov 27 Miss Florence Horsbrugh, Minister of Education, said that there were now the equivalent of 928 full-time dentists in the school dental service This was the highest figure so far recorded

Medical Association for the Prevention of War

The London branch of this association is holding a forum at 8 P M on Wednesday, Dec 9, at 45, Russell Square, W C 1, on the theme of Racial Discrimination, when Prof L S Penrose, F R S, will discuss the scientific basis of racial theories

Journées Médicales de France et de l'Union Française

Prof C Lian will preside over the journées which are to be held in Paris from April 21 to 24 Medicine and the Improvement of Life has been chosen as the general topic for the meeting Further particulars may be had from the secretariat, 12, rue Pierre Geofroix, Colombes (Seine)

Anglo-French Exchange Bursaries

Applications are now invited for bursaries which will be awarded in 1954 to young British doctors under the exchange scheme arranged by the French Embassy in London between the Institut National d'Hygiène in Paris and the Ciba Foundation in London

The grants (60,000 francs a month) will be awarded for two to four months to doctors who wish to obtain clinical experience or carry out medical research in France Application forms may be had from Dr G E W Wolstenholme director of the Ciba Foundation 41 Portland Place, London, W 1 The closing date for applications is Feb 22

Medical Artists' Association

Work to be submitted for the examination for the membership of this association should reach Miss Audrey Arnott, The Rotunda, Radcliffe Infirmary, Oxford, by Jan. 31 Application forms may be had from the hon. secretary, Miss Margaret McLarty, at the same address

International Organisation against Trachoma

The next meeting of this body will take place at Montre on Sept 11, 1954, under the chairmanship of Mr A. MacCallan. Offers of communications should be sent to secretary general of the XVII International Congress Ophthalmology, 100, 1st Avenue Buildings, Rochester, Mi U S A

British Association of Urological Surgeons

The annual meeting of this association will be held next year from June 24 to 26 in Dublin, under the presidency Mr Terence Millin The main subject chosen for discus is Irradiation Therapy in Urology Dr G W Blomfield wi be the opening speaker, and Mr E W Riches, Mr D Poole Wilson, Mr J D Fergusson, Mr R Cox, and M D M Wallace will also take part

---

The *Proceedings of the First International Congress on Medi Records*, which was held in London in September, 1952, have now been published Copies may be had from the hon. secretary of the Association of Medical Records Officers, Christie Hospital, Wilmslow Road, Manchester (26s plus postage)

Diary of the Week

DEC 6 TO 12

Monday, 7th

POSTGRADUATE MEDICAL SCHOOL OF LONDON, Ducane Road, W 12
4 P M Prof. A. Haddow Recent Trends in Experimental Pathology of Cancer

UNIVERSITY COLLEGE, Gower Street, W C 1
4 45 P.M Mr H Gutfreund, PH D Molecular Forces in Protein Solutions (First of two lectures.)

ROYAL EYE HOSPITAL, St George's Circus, S E 1
5 15 P M Dr T H Whittington The Refraction Case—Six Factors Producing Good Sight.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W 1
5 P.M Sir Henry Dale, O M, F R.S. Changes and Prospects in Medicinal Treatment. (First of three Harben lectures)

HUNTERIAN SOCIETY
7 30 P M (Talbot Restaurant 64 London Wall E C 2) Dr J Aldren Turner Mr H Osmond Clarke A Pain in the Neck

Tuesday, 8th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East S W 1
5 P.M Dr Maurice Davidson Medicine in Oxford—A Historical Romance. (First of two FitzPatrick lectures)

UNIVERSITY OF LONDON
5 30 P.M (University College) Prof Otto Koehler (Freiburg) Thinking Without Words

ROYAL EYE HOSPITAL
5 P M Prof. Arnold Sorsby Nature of Congenital Anomalies.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE
5 P.M Sir Henry Dale Changes and Prospects in Medicinal Treatment. (Second of three Harben lectures)

INSTITUTE OF DERMATOLOGY St John's Hospital, Lisle Street W C 2
5 30 P.M. Dr P D Samman Reticulosis.

WEST END HOSPITAL FOR NERVOUS DISEASES 40, Marylebone Lane W 1
5 30 P M Mr I R McCaul Investigation of Cerebral Tumour

CHELSEA CLINICAL SOCIETY
7 30 P.M (South Kensington Hotel, 41 Queen's Gate Terrace S W 7) Mr Dickson Wright Dictators and their Doctors

THE UNIVERSITY AND SURGERY*

M F A Woodruff
M.D., M.S. Melb F R C S
ROFESSOR OF SURGERY IN THE UNIVERSITY OF OTAGO
NEW ZEALAND

r is salutary for every university teacher to consider own particular discipline in relation to the purpose of university as a whole But what is the purpose of a versity ? I propose to examine three fundamentally erent answers to this question and to discuss their nificance for a teacher of surgery

he first, which Sir Walter Moberly (1949) calls the tian–Hellenic answer, is embodied in Newman's *e of a University* (1852) It affirms that the main ective of a university is intellectual culture True versity education thus avoids narrow specialism, on one hand, and superficiality, on the other, it

> ves a man a clear conscious view of his own opinions l judgements, a truth in developing them, an eloquence in ressing them, and a force in urging them It teaches to see things as they are to go right to the point, to ntangle a skein of thought, to detect what is sophistical l to discard what is irrelevant It prepares him to fill post with credit, and to master any subject with facility '

he second, or in Moberly's terminology the *liberal* wer is that the prime object of a university is the suit of new knowledge for its own sake irrespective its possible applications Communication of know ge, especially at undergraduate level is of secondary portance

The third, or *technological and democratic* answer is dominantly utilitarian It affirms that the function a university is to Serve the state by providing the perts and the ideas necessary to maintain material gress. Education must be strictly vocational, and the ue of research depends on whether or not it provides ults of practical importance. Learning for learning's ke is an idol to be demolished and, as Moberly puts it, the hero, or archetypal figure is the man who makes o blades of grass grow where one grew before This cept reflects the enormous development of applied ence and gains much of its strength from the fact that is just in this field that the universities are most closely touch with what Ortega denotes by culture "the al system of ideas of a period" (Ortega y Gasset 1946)

It is clear that these three concepts, if pushed to tremes, are mutually incompatible I believe never less that each contains elements of truth and that a thesis can and must be made I submit in short, at intellectual culture, vocational training and research form part of the complex function of a university

Intellectual Culture

Intellectual culture is certainly of fundamental portance For as Newman observes a cultivated ellect, because it is good in itself brings with it a wer and a grace to every work and occupation which it dertakes.' How may it be achieved ? It is not, in elf, a branch of knowledge but rather a healthy state of nd which can be developed only by study in some propriate field. As Newman remarks

> 'In saying that law or medicine is not the end of a versity course I do not mean to imply that the university es not teach law or medicine. What indeed can it teach all, if it does not teach something particular ?

This at once raises the question of what subjects and ares of study fall within the province of a university The vice-chancellor of Queen's University Dr Eric hby (1946) has suggested the following answer

> 'If the subject lends itself to disinterested thinking ; if generalization can be extracted from it ; if it can be advanced by research if in brief it breeds ideas in mind, then the subject is appropriate for a university If on the other hand the subject borrows all its principles from an older study (as journalism does from literature or salesmanship from psychology or massage from anatomy and physiology) and does not lend itself to generalization, then the subject is not a proper one for a university Let it be taught somewhere by all means but it is a technique not an exercise for maintaining intellectual health and the place for a technique is a Technical College

This answer is good so far as it goes, but it rather suggests that we may divide all conceivable subjects of study into two clearly defined categories—those which are technical and those which, for want of a better word, may be called cultural This is a dangerous fallacy and one to which academic people are liable it might well be called in Francis Bacon's terminology an Idol of the Quadrangle A more accurate view is expressed by Professor Montrose (1952), also from Queen's University who distinguishes three levels of education which he calls technical specialist, and general :

> *Technical education* may be briefly described as indoctrination. It does not consist in the mere imparting of factual information for theories may be taught and skills practised, while ability to apply knowledge to particular situations may also be required But the understanding is limited since acceptance of existing doctrine is assumed. The student submits to learning he does not master it by developing a real understanding, which comes from a creative and critical approach.
>
> *Specialist education* embraces technical education but proceeds to a higher level. It introduces the critical and creative approach by making the student aware of the problem character of the discipline and of the strength and fallibility of human solutions and problems, and also by inspiring him with the ideal of seeking for better solutions.
>
> *General education* embraces specialist study but takes it to the higher level appropriate to universities by making the specialist aware of the broad topics and general methods of other disciplines Without specialist study there is no penetration to the heart of the subject no travelling to its periphery where its relation to other subjects may be appreciated without general education the process required by the specialist approach itself is halted There are broad problems and *general methods common to many disciplines*, and progress in each is best assured by awareness that solutions of particular problems in each may be suggested or even elaborated in some other discipline

Professor Montrose's thesis does not differ essentially from that presented two years ago by Sir Harold Himsworth in a stimulating address on the University and Medicine in which he stated that the real difference between education and technical training is one of aim and purpose Himsworth made the further very important point that all education has its basis in technology

> Custom, he said has habituated us to the euphemism that learning the techniques of reading writing and mathematics, and acquiring a knowledge of foreign languages, are educative processes. But education in the higher sense the development of power to form judgments only becomes possible after such techniques have been acquired It can therefore be conceded at once that a modicum of detailed and technical knowledge is an indispensable foundation for higher education, be this classical or scientific. But this modicum must be such as to form the basis for the development of a representative selection of intellectual skills (Himsworth 1951)

Admittedly with some subjects it is almost impossible to get above the technical level ; in many others however the level reached depends rather on the teacher and the student than on the subject itself It has been abundantly proved that a study of the Classics can be a potent means of intellectual cultivation but that is not the only way The study of history philosophy modern languages, and literature, and (dare I add ?) mathematics physics, chemistry, and biology may be no less effective. Moreover it is well to remember that the study of any subject, including the so-called humanities, if wrongly conducted, can be a stultifying experience Byron's *Thoughts Suggested by a College Examination* are a pertinent reminder

---

* Inaugural lecture in the chair of surgery University of Otago medical school New Zealand, 1953

> " Happy the youth in Euclid's axioms tried
> Though little versed in any art beside ,
> Who, scarcely skill'd an English line to pen,
> Scans Attic metres with a critic's ken.
>
> Though marvelling at the name of Magna Carta,
> Yet well he recollects the laws of Sparta ,
> Can tell what edicts sage Lycurgus made,
> While Blackstone's on the shelf neglected laid ,
> Of Grecian dramas vaunts the deathless fame,
> Of Avon's bard remembering scarce the name
>
> Such is the youth, whose scientific pate
> Class-honours, medals, fellowships await."

Vocational Training

Today, with the almost complete disappearance of the leisured class, the demand for vocational training is greater than ever before In many vocations the essential qualification is the ability to perform certain clearly defined tasks and to react correctly to stock situations ; for these training at technical level is sufficient There are other vocations, however, exemplified by the so-called learned professions, for which purely technical training is hopelessly inadequate These demand, in addition to specialised knowledge and special skills, educated minds capable of dealing with new and complex situations It seems self-evident that recruits for these professions need both a university education and a period of professional apprenticeship , the real point at issue is the extent to which university studies should relate to specific professional requirements My own view is that professional training can be of great vocational value and is by no means incompatible with Newman's concept of the university's function Moreover, if professional training and university education are divorced, the former will almost inevitably be conducted at a purely technical level, and the latter is likely to be superficial or even perfunctory I therefore hold that the practice, which has been followed since the Middle Ages and which Newman himself accepted as proper, of the universities assuming a large measure of responsibility for training recruits for some at least of the professions is sound, and indeed essential, provided always that the objectives we have been discussing are kept clearly in view If this plan is adhered to a period of apprenticeship is still necessary, but it can be effectively integrated with the early training , and in some instances, as in Medicine, it *may begin before graduation*

The objection may be raised that the universities' hands are tied because, to an ever-increasing extent, entry into the professions is being controlled by bodies such as the Law Society and the General Medical Council, which prescribe courses of training and either conduct, or in large measure control, qualifying examinations.

It is certainly conceivable that this might give rise to difficulty , in fact, however, it does not appear to have *done so* Certainly, *so far as the profession of medicine* is concerned—and this is the only profession for which I can speak—the General Medical Council in Britain, and corresponding bodies in the Dominions, have done an enormous amount to raise professional standards without exerting any harmful influence on the universities

Research

The search for truth is complementary to the other *functions of a university Not only is the cultivated* intellect of vital importance in this search , the pursuit of any scientific discipline is a potent means of promoting intellectual growth and of developing that imaginative insight which, as Whitehead (1932) has used, is the hallmark of the educated man

The search must be free and unfettered
siderations of expediency This claim is often
on the ground that a discovery which does n
to have any immediate application often prove
be of great practical importance, but this is be
question. I believe, as anyone undertaking fur
research must believe, as an article of faith, th
worth pursuing for its own sake. It is nat
indeed salutary, to have periods of doubt about
it is comforting to find that scientists of the
Sir Macfarlane Burnet have experienced suc
(Burnet 1948), but we must overcome them.

At the same time we must avoid the opposit
of despising research of an ad-hoc kind. S
application is certainly not essential, but to
consider the impact of discoveries on the profes
in industry or, worse still, to avoid deliberately
which seem likely to have a short-term appl
surely academic affectation of a most objection
Happy indeed is the man whose work com
possibility of fundamental discovery with the s
immediate problems, for he easily avoids bo
errors.

The Place of Surgery in the Universit

We are now in a position to consider the
surgery in the university It will be conve
arrange the discussion under three main h
undergraduate education, postgraduate traini
research.

UNDERGRADUATE EDUCATION

The medical student begins by studying t
sciences of physics, chemistry, and biology ; he t
on to study the structure and function of the
body After three years, while still an underg
he becomes an apprentice, and is brought into
with men, women, and children ill in mind or b
begins to learn something of the value, and th
tions, of the scientific method applied to the
disease , and at the same time he is introduce
human and social problems occasioned by birth,
old age, disease, and death.

It is hard to imagine a more enriching experie
field of study better calculated to bridge the wide
between the humanities and the sciences , Why
the level of *general education attained* by the
student so disappointingly low ? I believe t
explanation lies not in the nature of the subjects
nor in the calibre of the students, but in our t

In the first place, we have been too much sy
demands from various sections of the profession t
this or that because it will be important in practic
object should not be to produce general practi
or surgeons, or pathologists, or research-worke
graduates who are totipotent, being capable of di
ating during the postgraduate phase of their app
ship in various ways according to their ind
abilities, inclinations, and opportunities.

Secondly, we teach too many facts. There
many subjects that few if any are studied
cramming is almost inevitable, and the student h
time to think for himself

Thirdly, insufficient effort is made to help s
with the difficult intellectual and psychological
ments necessitated by the transition from prelin
clinical work.

The position cannot be improved by introducin
so-called cultural subjects The right approach
prune, and to set each subject in proper perspect
asking ourselves how much a student can reaso
expected to learn about it, what contribution it can
towards general education, and how it should be t

Let us try to answer these questions as r
surgery

How much Surgery should a Student be Expected to Learn?

In my own university it was customary to publish in the calendar a syllabus for each subject in which degree examinations were held. Under *Surgery* one found the alarming pronouncement that *the syllabus includes the whole subject.* Fortunately our teachers were too wise to treat this seriously, or our state would indeed have been parlous. In contrast it is sometimes suggested that since only a small proportion of students are going to be surgeons, and then only after years of postgraduate training, there is no need to teach surgery at all.

Most surgeons, and most teachers, would reject both these extremes: the first because the surest way of teaching too little is to try to teach too much, the second because, as I have already tried to show, it is based on a misconception of the nature and purpose of medical education. There is, however, much difference of opinion regarding the precise direction we should take.

My own view is that when a student sits for his qualifying examination he should have learnt to take an accurate history and to conduct a proper physical examination, and should be able to diagnose common surgical disorders, especially those requiring prompt treatment. In cases where he is unable to make a precise diagnosis he should know when and where to seek expert advice. Finally, he should be familiar with the principles underlying the treatment of patients before, during, and after operation, and should have a general idea of the scope and the limitations of present-day surgery.

Even this modest goal is not always reached. But if the teaching of medicine and surgery are properly coordinated, and if both are based on a firm foundation of anatomy, physiology, and pathology, it should be well within the reach of every student who does his work in the wards and the outpatient department conscientiously.

What Contribution can the Study of Surgery make towards a Student's General Education?

In the first place, it is not difficult to relate the study of surgery to that of other subjects. The most obvious links are with other clinical subjects and with the biological sciences, but there are many more. Contact with patients inevitably introduces psychological problems, and experience of suffering, even if vicarious, raises issues of profound metaphysical and theological import. These issues form the subject of an immense amount of literature, in which the student may browse at will: his main difficulty is to know where to begin. And if yet more links are required, one may consider the history of surgery, or the effect of surgical progress on the history of mankind.

Secondly, surgery provides excellent opportunities for training students to make accurate observations. And it is, I believe, all to the good that in many cases observations of crucial importance have to be made with the unaided senses.

Thirdly, the student learns to draw reasonable inferences from his observations. His capacity for logical thinking grows, and he develops a capacity for making sound intuitive judgments when logic can carry him no further. It is important for him to learn to distinguish between these processes, and to determine by introspection how he has reached a given conclusion. This naturally raises questions of an epistemological character, and the student who wants to pursue them can be introduced to Locke, Hume, Kant, Russell, Whitehead, and the rest.

Finally, the student learns to make up his mind. Of course the ultimate decision about what treatment to advise rests with the surgeon in charge of the case, but it is, I think, essential for the student to decide what he would do if the responsibility were his. It is far better for him to make mistakes than to remain for ever a prey to indecision. In surgery, more often than in medicine, important decisions have to be made quickly, and it is perhaps this fact, more than anything else, which gives to the study of surgery its distinctive character.

How should the Teaching of Surgery at Undergraduate Level be Organised?

Lectures, lecture demonstrations, and bedside instruction are all of value, but I am wholeheartedly in agreement with Mr David Patey when he says that the pivot on which the whole British system of clinical instruction turns is association of the undergraduate with the work of the various clinical units in an active responsible capacity. This requires a high ratio of patients to students and a curriculum which leaves plenty of free time for ward work (Patey 1952).

This system was developed in the days of honorary hospital staffs. Today almost everyone is paid, but it is still possible, and in my view essential, for much clinical teaching and supervision to remain the responsibility of men engaged in the hurly-burly of private consultant practice. To keep a proper balance, however, and to achieve continuity between preclinical and clinical work, this responsibility should, I believe, be shared with men who are full-time members of the staff of a university. Such men must be competent surgeons, and they must therefore be actively engaged in surgical work. In addition, however, they must be interested in education in the widest sense of the word.

My distinguished predecessor has suggested that it is nowadays impossible to be a professor of surgery because the field is so vast that no-one can compass it: he therefore favours the title 'director of clinical studies.' Mr Patey, too, appears to be of the same opinion. With great respect I disagree, for what is needed is not merely someone to coördinate clinical teaching but also someone to bridge the gap between hospital and university, someone able to speak in the university on behalf of the profession and to foster in the hospital the ideals of the university. Exhaustive knowledge is fortunately not necessary. If it were, there would be no professors not only of surgery but also of mathematics, physics, history, philosophy, and every other subject worthy of a university.

POSTGRADUATE TRAINING

The main responsibility for maintaining professional standards in surgery rests with the Royal Colleges. It is therefore in my view both right and inevitable—though it is sometimes deplored in university circles—that the colleges should to a large extent determine the pattern of postgraduate training, and should conduct examinations. It is also right and inevitable that the medical graduate who wants to become a surgeon should spend some years in hospital posts, working first under close supervision and later enjoying a measure of responsibility commensurate with his ability and experience.

There is room, however, for fruitful collaboration between the colleges, the hospitals, and the universities, and it would be a tragedy if this were not maintained.

In the first place, as the colleges have wisely recognised, a surgeon needs a more thorough knowledge of anatomy, physiology, and pathology than he obtained as an undergraduate, and the universities can cater for this need.

Secondly, it is, or should be, of great advantage for trainees, especially those who hope to join the staff of a teaching hospital whether in a full-time or a part-time capacity, to spend part of their postgraduate apprenticeship in a university surgical unit. As a general rule this should, I believe, be a unit which is responsible for undergraduate teaching, partly because the opportunity to teach also at postgraduate level is a great stimu to members of the unit, and partly because it is for the trainee to do some teaching himself.

What of courses of instruction in surgery? speak from experience because I have never let alone conducted, a formal course of postgraduate instruction, but I have an uneasy feeling that such courses are often regarded by fellowship candidates merely as short-cuts which will help them to pass their examination If this danger can be avoided, a well-planned course may be of real value, but no amount of formal instruction is an adequate substitute for practical experience

RESEARCH

A surgeon may undertake research with the object of advancing his own subject by developing new methods of diagnosis and treatment Alternatively, he may seize the opportunities which often arise in surgical practice of making new discoveries in anatomy, physiology, or pathology

In both types of research close liaison between the wards and the laboratory is of fundamental importance Indeed all the really great advances in surgery—such as the control of infection by antisepsis, asepsis, chemotherapy, and antibiotics, the use of blood transfusion and the discovery of accurate methods for controlling fluid and electrolyte balance, and the development of appropriate operations for treating lesions of almost every part of the body—have been brought about by combined clinical and laboratory research or by the clinical application of laboratory discoveries So swiftly has discovery followed discovery, however, that today a gap—one might almost say an iron curtain—has developed between the clinician and the laboratory worker, and each finds the language of the other almost incomprehensible

This gap can be bridged only by men with an interest in, and preferably first hand experience of, both fields Such men are rare and, perhaps on that account, often considered eccentric They are, however, in the authentic Hunterian tradition, for John Hunter—let us never forget—was both a surgeon and an experimental biologist It is, I believe, one of the important duties of a university clinical unit to guard this tradition and to provide an environment in which those who seek to follow it can flourish.

Summary

What I have tried to show may be summarised quite briefly It is, firstly, that surgery as a subject is a proper one for university study, and, secondly, that surgery as a profession needs men and women with knowledge and skill, and with that breadth of outlook which can come from university education at its highest level

I gratefully acknowledge the permission of the authors and the respective publisher or editor, to quote the words of Dr Ashby Professor Montrose and Sir Harold Himsworth.

“ The welfare state has emerged by an evolutionary process in the sphere of social affairs but without sufficient education (or propaganda) to take the people along with all its implications The general attitude is unfortunately that of *taking* out of the national pool and putting nothing back There are obviously circumstances where only the resources of the State can provide complicated treatment or care over a long period for gross abnormality of physical or mental health Even here, as suggested earlier more could be done to help parents to accept responsibility for home care, encouraging them to overcome their trouble by living with it instead of passing it on to someone and somewhere else Put this way and remembering that it ’ is a child in trouble the rôle of the State should be more clearly that of a friendly adviser rather than providing a plain van to take difficulties away —ALAN MONCRIEFF *Child Health and the State* 1953, p 45

THE SUPRAPUBIC CATHETER

A METHOD OF TREATING URINARY RETENTION

C G SCORER
M B Camb, F R C S, F R C S E
CONSULTANT SURGEON, HILLINGDON HOSPITAL, MIDDLESEX

PUNCTURE of the distended bladder through the abdominal wall has many advantages but has always been regarded as dangerous If the puncturing instrument enters the peritoneal cavity it may damage the bowel or the omentum, while leakage of urine along its track may give rise to prevesical extravasation of urine and spreading cellulitis Either of these complications may be fatal

In 1943 Riches described a method of treating urinary retention caused by injuries to the spinal cord He devised an instrument by which a small rubber catheter could be inserted into the bladder by a stab through the skin and linea alba In 1949 he advocated the same technique for chronic urinary retention due to prostatic obstruction, but gave no details.

During the past three years this method of suprapubic catheter drainage has been used in almost all types of urinary retention coming under our care, whether due to acute or chronic obstruction or paralysis This paper contains a review of 150 consecutive cases

The Urethral Catheter

From time immemorial the relief of urinary obstruction has been by the passage of a urethral catheter If urine fails to make its way along the natural channel, it is rational to reopen the passage by the use of a curved and hollow tube Such, indeed, was the treatment until the end of the 19th century, when, through the work of McGill of Leeds and Freyer of London, suprapubic removal of obstructing tissue became an established and successful operation Thereafter, as the technique of prostatectomy became surer and safer, the catheter was used less and less Its use is still necessary before operation when urinary retention is present, and it is essential after operation while the bladder and prostatic capsule are healing

But the urethral catheter can be a troublesome instrument It cannot with certainty be retained in the urethra of a restless and mentally confused patient, it is recognised as the prime source of infection of the urinary tract, with all the serious or disastrous consequences, it is a cause of irritation and discomfort to the patient, and on occasion it is very difficult, if not impossible, to pass.

Some say that the catheter should not in any circumstances be used before operation, and that the correct way to treat urinary retention is to relieve the obstruction forthwith This surely is a counsel of perfection It presupposes a fully equipped urological unit capable of giving a twenty-four hour service including radiology and if need be biochemistry At present it can be achieved only by the few Secondly, and more important, it assumes that all such patients admitted to hospital are fit for major surgery In our experience this is far from true

The use of the suprapubic catheter to relieve urinary retention obviates to a large extent the difficulties inherent in the urethral catheter it is safe, the technique is simple, and the patient suffers only the slightest disturbance At any time subsequently the patient can undergo an operation to relieve the obstruction, or, should he be considered permanently unfit for a major surgical operation, the catheter can be retained or a larger one substituted.

Technique of Puncture

On admission to the ward the patient is examined and, if he is in pain, morphine is given The catheter

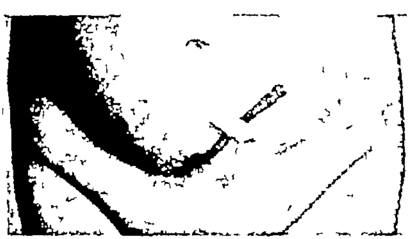

Fig. 1—Urinary retention treated by suprapubic catheterisation in patient aged 75 Wound is 3 in. above symphysis pubis.

s then introduced under local anæsthesia with the atient in his bed in the ward Several points need mphasis.

To define the size and outline of the bladder, percus ion, the customary method, is unreliable. In acute etention the circumference of the tense bladder can ily be felt after the protective spasm of the abdominal uscles has been relaxed with morphine. In chronic or aralytic retention the bladder is often larger, and no ifficulty has been experienced in palpating its outline A point on the skin is then chosen 1 inch below the level t which the anterior surface of the bladder curves ackwards to the superior It has, however, not been ound to be of any value to have the site of entry more han about 3 inches above the pubes (fig 1)

The question may fairly be asked how often is the eritoneum penetrated or bowel or omentum damaged ?

Anatomically the procedure appears to be safe. Rogers (1952) describes the peritoneal reflection on the anterior urface of the bladder in the following words :

> "When the fundus of the bladder is 2 inches above the pubes the peritoneal reflection is probably not more than /4 inch above the same bone When the fundus of the bladder s midway between the umbilicus and the pubes there may be 2 inches of the anterior abdominal wall in the middle line and immediately above the symphysis devoid of peritoneal lining Thus it happens that the distended viscus may be readily tapped above the pubes without the peritoneum being wounded."

This suggests that, when the bladder is enlarged up to, or almost up to the umbilicus, as in almost all our cases some 3 inches or more of bladder is free from peritoneal covering above the symphysis pubis.

But experience is more eloquent. In 150 cases no complication has arisen by damage to peritoneal contents. Moreover 89 of these cases were treated by house-surgeons whose experience in operating was negligible and to whom the technique had been demonstrated but once or twice

In some cases at operation or at necropsy it has been found that the lowest fold of peritoneum consisting of two apposed surfaces lying on the distended anterior bladder wall, has been perforated The significance of this will be discussed later

When the catheter is being introduced, it has proved necessary not only to make a small vertical incision in the skin 1/4–1/2 inch in length but also to cut through the strong fibrous tissue of the linea alba to the same extent. If this is not done, the catheter may be torn from the instrument while it is being introduced.

Position of Catheter

After the catheter on its introducer has been carried past the linea alba on to the bladder surface a short sharp stab is made with due warning to the patient that he will feel momentary pain or discomfort. A boring movement must not be used, for it tends to drag the catheter off the introducer or to dissect the layers of the bladder wall one from another so increasing the likelihood of bleeding

With the catheter in the bladder the introducer is removed and the advancer inserted. The catheter is then pushed onward to the bottom of the bladder at a point just behind the trigone (fig 2) This is an important step The catheter should be well down otherwise, when the bladder contracts on emptying (fig 3) the open end may be drawn up to or out of the wall with consequent likelihood of a leak of urine into the prevesical tissues.

A 'Nylon' stitch is used to secure the catheter to the skin and this is reinforced with adhesive strapping We have learnt that in a restless patient the shield devised and illustrated by Riches is insufficient to hold the catheter in position.

In several cases the track of the catheter has been dissected when prostatectomy was performed, or at necropsy After traversing the abdominal wall at right angles to the skin surface the catheter passes through the prevesical fat to a point on the anterior aspect of the bladder which varies with the degree of its distension When the bladder is empty the catheter enters below the level of the top of the symphysis pubis (fig 3) If the bladder is filled, its wall slides up the catheter, reducing the length of its extravesical course and increasing the length which remains inside the bladder

Extravesical Leak of Fluid

Of the 150 cases in this review some degree of urinary leak outside the bladder has been noted in only 2 In

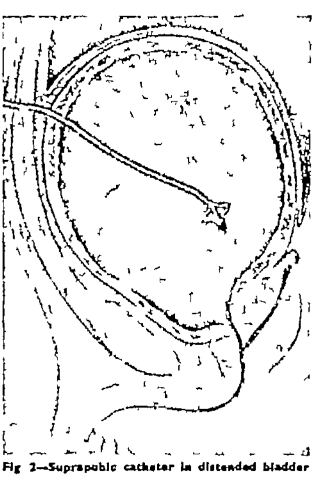

Fig 2—Suprapubic catheter in distended bladder

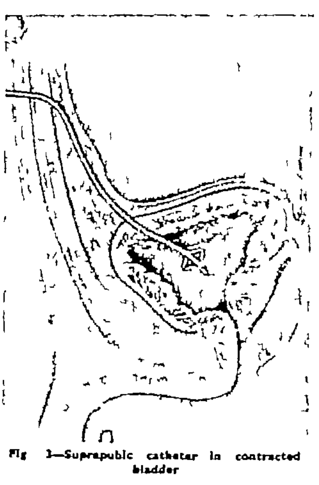

Fig 3—Suprapubic catheter in contracted bladder

the first the abdominal wall was dissected in the way described for the standard operation of suprapubic cystostomy, leakage took place because the hole into the bladder was too large In the second the catheter was apparently pulled almost out of the bladder In each case the tissues were œdematous and difficult to handle when prostatectomy was done, and adequate exposure of the bladder was much impeded

No case of extensive urinary extravasation or of spreading cellulitis has been seen, but a little prevesical œdema is sometimes found

Choice of Patient

Since Sept 1, 1949, suprapubic catheterisation has been used with increasing confidence and frequency Between this date and January, 1953, 233 cases of acute or chronic urinary retention have come under our care 150 were treated by suprapubic catheterisation, while 83 were treated by other methods or did not require treatment

	No of cases
Indwelling urethral catheter	58
Relieved spontaneously	10
Immediate prostatectomy	5
Moribund no treatment	4
Dilatation of stricture	3
Immediate suprapubic cystostomy	2
Cystodiathermy of papilloma	1
	83

The group treated by urethral catheterisation was largely composed of three types of case (1) those admitted to, or developing retention in, another ward in the hospital, (2) those known or suspected to have carcinoma of the prostate, and (3) those in whom some local anatomical reason precluded the use of the suprapubic catheter

As our experience has increased, the urethral catheter has been used less There are, nevertheless, certain cases in which its continued use is advisable or essential

(1) When a young patient develops urinary retention during an attack of pneumonia or congestive heart-failure, and the disease is not serious enough to keep him in bed more than a few days, it is better to use a urethral catheter This turn of events is not uncommon An indwelling urethral catheter is tied in, but removed as soon as the patient can get out of bed and walk Normal micturition then returns

On the other hand, some of our most rewarding cases have been in older men desperately ill in a medical ward whose retention has been relieved by suprapubic catheterisation and who, some four or six weeks later, have been fit enough for prostatectomy

When the bladder has to be drained for a long time the use of a urethral catheter too readily leads to infection, we prefer to resort to suprapubic drainage

(2) Suprapubic catheterisation has hitherto been thought inadvisable in patients with prostatic carcinoma Many such patients respond well to œstrogens with or without a short period of urethral catheterisation Others require endoscopic resection Our fear has been that in cases of carcinoma, suprapubic drainage of the distended bladder may lead to a permanent fistula, but it is probably unfounded We have not seen any case of fistula, and the wound usually closes with astonishing rapidity

(3) Where there is no free access to the anterior bladder wall or where the tissues are infected, suprapubic catheterisation should not be used For instance, when the peritoneal cavity has been drained suprapubically for peritonitis the scar may prevent the peritoneal fold from rising with the bladder as it distends This is usually obvious on palpation The bladder lies away from the abdominal wall, and the scar acts as a warning As an example of infection, a man was admitted with retention of urine and a cellulitis *of the lower abdominal* wall A urethral catheter was used He was subsequently found to have a breaking down vesical carcinoma.

Results of Treatment

After the initial relief of urinary obstruction the patient's general condition is assessed and further investigations are made The disposal of 150 cases after preliminary treatment by suprapubic catheterisation was

	No of cases
Prostatectomy	87
Urethral dilatation for stricture	5
Suprapubic cystostomy	23
Relieved without further treatment	12
Died without further treatment	23
	150

A few words of explanation must be said about each group

PROSTATECTOMY

When prostatectomy is to be performed the diagnosis is confirmed by cystoscopy immediately before the operation If a suprapubic rather than a urethral catheter has been used, the urethra will be uninfected and the bladder base will not have been irritated by an indwelling catheter No traumatic or infective œdema will obscure the field, and the state of the trigone and surrounding tissues can be readily judged

If prostatectomy is indicated, the suprapubic catheter is removed and the operation of choice is done A midline incision is made from the site of entry of the catheter to the symphysis pubis No attempt is made to search for and to close the hole in the bladder through which the catheter passed, this has been found to be unnecessary

In retropubic prostatectomy the approach is unimpaired If a transvesical operation is performed, the bladder may be contracted and difficult to distend in the same way as it is after long continued drainage by urethral catheter But this is by no means invariable, even when the catheter has been in for several weeks.

The choice of operation is in part a matter of personal preference and experience The type of prostatectomy done was as follows

	No of cases
Retropubic enucleation	55
Transvesical enucleation	25
Endoscopic resection	7
	87

A retropubic operation was usually chosen for the fit active men, and the transvesical approach with suprapubic drainage for the old and frail It was, of course, in the latter that prolonged catheter drainage was necessary The perurethral method was used in cases of carcinoma or where prostatic enlargement was slight

The length of time the suprapubic catheter was retained before operation is shown in the accompanying table

Catheter retained (days)	Retropubic enucleation	Transvesical enucleation	Endoscopic resection	Total
1–5	28	7	2	37
6–10	22	6	1	29
11–15	2	4		6
16–20	1	1	1	3
21 or more	2	7	3	12
	55	25	7	87

URETHRAL DILATATION

This was done in the operating theatre as soon as a stricture was diagnosed The suprapubic catheter was then spigoted, and the patient instructed to pass his urine in the normal way The catheter was removed forty eight hours later, urine seldom leaked, and then only in the first few hours

SUPRAPUBIC CYSTOTOMY

n the early days this operation was performed either en it was clear that prostatectomy never could be ie—e.g., in a patient already suffering from gastric rcinoma—or where fitness for operation was improbable thin a month With experience however we have nd fewer indications for its use It is in itself almost serious as a quick enucleation of the prostate and our 23 patients 8 died within a few days of the ration.

In addition the suprapubic catheter can be retained several months and provides quite adequate bladder ainage After two or three weeks the original catheter y be superseded by a straight soft rubber urethral theter as described by Riches it is inserted immedi ly *after removal of the first.* *We have found it advis*le to keep the patient in hospital during this waiting riod There still remain a few patients who because ey refuse operation or because an interval of two or ree months is deemed advisable, will return home with e large de Pezzer catheter for bladder drainage

RELIEVED WITHOUT FURTHER TREATMENT

In this group are those patients with negligible prostatic largement or congestion who need no surgical relief stoscopy establishes the diagnosis, and thereafter e suprapubic catheter is spigoted and normal micturi n returns.

There were 2 cases of paralytic distension in one bes dorsalis was diagnosed after the retention had been lieved in the other, paraplegia was caused by a mour of the spinal cord. In both cases normal micturi n was regained after treatment of the primary disorder

DIED WITHOUT FURTHER TREATMENT

The figure of 23 may well be considered large, but alysis shows that in most of them urinary retention s merely an incident in the life of a patient already ill dying from a serious medical disorder The relief of tention was essential for the patient's comfort, but ntinued decline was inevitable

It is in such cases that the suprapubic catheter is a on. It is easily inserted and when in position it causes e patient no discomfort It can be retained indefinitely d seldom needs attention apart from periodic changing n our experience it is far less often pulled out than an dwelling urethral catheter

In 16 of the 23 cases the primary cause of death was related to the urinary condition as follows heartilure (4 cases) pneumonia (4) cerebral hæmorrhage (3) ulmonary tuberculosis (2), paraplegia (2, caries and condary carcinoma) and pulmonary embolus (1) All ese patients died within a month of admission

2 patients died from uræmia one within forty eight ours of admission (blood urea 254 mg per 100 ml.) d the other, after a fortnight, with a blood urea level hich never fell below 400 mg per 100 ml.

Of the remaining 5 fatal cases some incident relating o catheterisation may be considered partly responsible r death In 1 patient, aged 85 a urethral catheter was peatedly pulled out, and he died from pyelonephritis wo days after suprapubic catheterisation the suprapubic catheter should have been used on admission In 2 others, aged 78 and 83, the suprapubic catheter came out after they had been sent home. Both died from pyelonephritis after retention of urine had recurred either should have gone home at that stage. In a 4th ged 87 the catheter was reinserted by a male nurse ho failed to reach the bladder peritonitis followed ore precise details are not known, but it is clear that the reinsertion of a suprapubic catheter is a skilled task and must be done at once In the last a man aged 74 already in uræmia (blood urea 169 mg per 100 ml) died from pyelonephritis because of blocking of the catheter, which was not adequately cleared

Complications of Suprapubic Catheterisation

In the present series complications have been remarkably few, and all can be overcome

Displacement of the catheter is the commonest through inadequate methods of tying in, the catheter slips out. If this happens and urinary retention has recurred the catheter may be reinserted by the same technique as was used for its first introduction. If the accident is recognised as soon as it has happened, a urethral catheter can be inserted down the track and into the bladder without difficulty If the track cannot be found a urethral catheter must be used rather than allow retention to recur with the possibility of an ascending urinary infection.

Epididymo-orchitis has been seen once. This was in a patient whose prostatectomy was delayed because of severe acute asthma and bronchitis During his convalescence his catheter was spigoted and he was encouraged to try to pass urine normally A bilateral infection ensued

Urinary extravasation has been seen in 2 cases, as mentioned above, and is explained by a technical error in introducing or managing the catheter There has been no case of spreading cellulitis or prevesical suppuration even where the catheter had to be reintroduced after slipping out.

Peritoneal perforation is known to occur occasionally (we have seen it on 6 occasions) but provided the outline of the bladder is carefully determined before the catheter is introduced no trouble arises from damage to bowel or to omentum (a complication which we have not seen) The fact that a portion of the catheter passes through the peritoneal cavity appears to be of no significance, though of course it is undesirable that it should do so If the bladder can be felt lying against the anterior abdominal wall introduction of a suprapubic catheter is safe

Hæmorrhage to a mild degree usually follows introduction of the catheter occasionally it is moderate No retention of urine was observed but a clot 2 inches in diameter was found in the bladder of a man who died from bronchiectasis and bronchopneumonia. Retained clot should be evacuated by cystoscope and suction.

Conclusions

Suprapubic catheterisation for treatment of acute and chronic urinary retention has been tried in 150 cases It has proved safe and simple Minor modifications have been made in the technique first described by Riches

It has definite advantages over the urethral catheter It is more comfortable because the patient can get out of bed and walk about remaining up all day Infective complications are reduced and there is no urethritis It does not interfere with the subsequent treatment of obstruction of the bladder neck or of the urethra by whatever technique is considered desirable Cystoscopy is made easier and more accurate. Finally the opinion of the ward sister and nurses is convincing—the patients are more contented and easier to nurse

Thanks must be accorded to Mr H G Hanley in whose unit and under whose inspiration this work was done It would have been impossible without the coöperation of a succession of enthusiastic and able house surgeons. I am grateful also to Mrs. Freda Wadsworth for her drawings, and Mr E Stride A.I.M.P for the photograph.

From the Institute of Obstetrics and Gynæcology, Hammersmith Hospital, and Bernhard Baron Memorial Research Laboratories, Queen Charlotte's Maternity Hospital, London

Yellow pigmentation of the brain is a striking complication in some cases of neonatal jaundice Although this pigmentation is not always confined to the nuclear masses, the term kernicterus or nuclear jaundice seems to be applied to any type of brain jaundice in which the nuclei are chiefly involved

The experience of one of us (Claireaux 1950) seemed to suggest that the condition was invariably associated with *icterus gravis neonatorum resulting from* hæmolytic disease Similarly, Potter (1952) stated that she had never observed icterus of the brain complicating conditions other than erythroblastosis Nevertheless the work of Aidin et al (1950), Zuelzer and Mudgett (1950), and Govan and Scott (1953) showed that nuclear jaundice was not uncommonly found in infants in whom the effects of rhesus iso immunisation could be excluded Indeed, Aidin et al remarked that, far from being the only cause of nuclear jaundice, hæmolytic disease was not even the commonest, they found nuclear jaundice in 16 6% of premature infants who came to necropsy

For this reason we have inquired into the incidence of both types of icterus of the brain in 376 necropsies of liveborn infants at Queen Charlotte's Maternity Hospital and Hammersmith Hospital during the five years 1948–52

A further problem of great importance is the nature of the pigment responsible for the yellow staining of the brain The suggestion has been made (Pickles 1949, Küster and Krings 1950) that this pigment may be the cause of brain damage Dereymaeker (1949) found that the staining reactions and solubilities of this pigment were those of bilirubin However, the assertion of Schmorl (1904) that staining was due to an abnormal pigment has been renewed by Bevis (1952b), who states that the pigment is mesobilifuscin arising from an underlying metabolic disorder

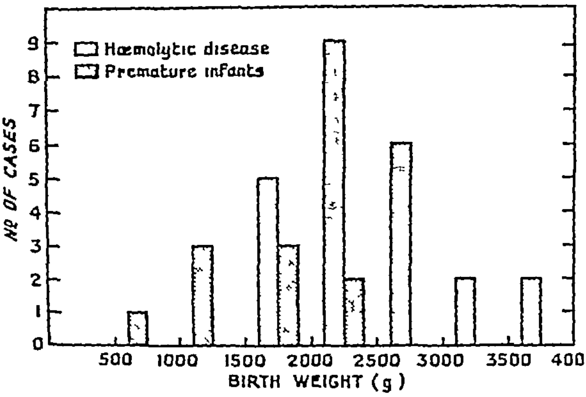

Fig 1—Distribution of birth weights among 9 babies with brain icterus associated with prematurity and 24 babies with brain icterus associated disease.

As a preliminary step in the investigation of the brain pigment Cole and Lathe (1953) have described a chromatographic method of fractionating bile pigments This method has now been applied to the study of the brain pigments in four cases of icterus of the brain, and to the examination of the serum pigments to which the brain is exposed in hæmolytic disease of the newborn

INCIDENCE OF BRAIN JAUNDICE

During 1948–52 at Queen Charlotte's Maternity Hospital and at the Institute of Obstetrics and Gynæcology, Hammersmith Hospital, there were 376 necropsies of liveborn infants Among these there were 33 cases of brain jaundice (8 8%) Of these 33 cases 24 (73%) showed evidence of rhesus iso immunisation, the remaining 9 were all premature infants in whom no evidence of rhesus incompatibility was found Of the 24 cases of hæmolytic disease 13 were males and 11 females, of the 9 other cases 6 were males and 3 females.

MATURITY OF INFANTS

The birth weight of the infants with hæmolytic disease was partly determined by the fact that pregnancy was terminated spontaneously or electively in all but 3 cases, most of them at 36–38 weeks' gestation One pair of affected twins of 34 weeks' gestation is included. The distribution of the birth weights of this group of infants is shown in fig 1

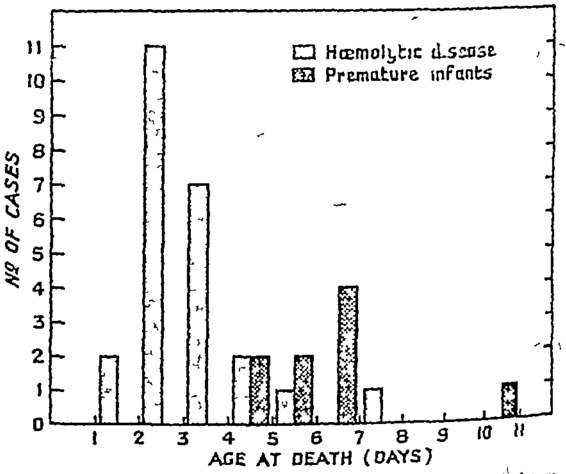

Fig 2—Distribution of age at death among 9 babies with brain icterus associated with prematurity and 24 babies with brain icterus associated with hæmolytic disease.

The other group of infants were all premature with birth weights well under 2500 g (fig 1) One infant weighing 640 g was delivered spontaneously at 28 weeks There were three twins in this group Their partners had also been jaundiced after birth but recovered.

TIME OF DEATH

There was a striking difference between the two groups. The infants with hæmolytic disease seldom survived more than four days, but no infant of the premature group died before the fifth day (fig 2)

CLINICAL FEATURES IN THE INFANT

All the infants with hæmolytic disease were rhesus positive and gave a positive Coombs test The hæmoglobin level of the blood varied from 24% to 140% (Haldane) Red blood-cells varied from 1,900,000 to 5,500,000 per c mm All the infants had moderate to severe jaundice which appeared within the first two days The liver and spleen were enlarged in 11 cases, the spleen alone in 8 cases, and in the remaining 5 no enlargement was found. In 12 cases an exchange od transfusion was given and in 3 cases a simple ect blood transfusion was given In 1 case an exchange nsfusion was attempted but failed In the remaining ases no transfusion was given. In these 8 cases the moglobin level was well over 100% and varied from to 140% (Haldane)

of the 9 premature infants were rhesus positive and as rhesus-negative, in 4 no information is available e Coombs test was negative in all 9 infants. The depth jaundice varied considerably There was 1 case of pato-splenomegaly 1 infant had gastric and pul nary hæmorrhage, 1 was deeply jaundiced and eloped peritonitis as a result of perforation of the um after an ileocæcal intussusception, 1 developed onchopneumonia; and the remaining 5 showed no usual features apart from jaundice. There were thus y 2 cases related to infection

CLINICAL FEATURES IN THE MOTHER

None of the 23 mothers of the infants with hæmolytic ease was a primipara, 10 of them were in their second gnancy, and 8 in their third. In 13 cases the prog ncy was terminated at the 36th–38th week because of molytic disease, this was done by artificial rupture the membranes in 10 cases and by elective cæsarean tion in 3 cases. Spontaneous labour took place at m in 2 cases at the 42nd week in 1 and before the th week in 7 All the pregnancies had been uneventful the 1 pregnancy which produced twins and terminated ontaneously at 34 weeks both twins were affected. All mothers were rhesus-negative and had antibodies in eir serum

Of the 9 mothers of the premature infants 5 were uniparæ 2 of them bore twins at 32 weeks gestation d 1 of these infants had acute hydramnios 1 had a vere antepartum hæmorrhage at the 32nd week and s delivered by cæsarean section, and 2 had uneventful egnancies. Of the 4 mothers who had previously borne ildren 1 had a twin pregnancy complicated by dramnios 1 had a slight antepartum hæmorrhage m a lateral placenta prævia 1 had an uneventful egnancy which was suddenly terminated at 26 weeks the spontaneous onset of labour, and 1 had an eventful pregnancy which terminated spontaneously 32 weeks. 7 of the mothers were rhesus positive, and one had antibodies in her serum. The incidence of normalities during pregnancy in this group was not gher than would be expected in any series of premature iveries.

Pigment in the Brain

The distribution of pigment in the brain was somewhat adable, and no distinction could be made between the o groups of cases. In 6 infants with hæmolytic disease d in 2 premature infants there was general diffuse ellow staining of the brain in addition to the nuclear gmentation. In 2 infants the periventricular white atter in the cerebrum was stained, and in 1 the peri queductal tissue was yellow In the remainder various uclear structures were involved.

CASE SUMMARIES

The pigment responsible for colouring the affected eas of the brain was extracted in 4 cases 2 in infants ith hæmolytic disease, and 2 in premature infants The nical and pathological findings in these cases were as llows

Case 1.—Male Birth weight 2732 g Spontaneous vertex livery at 37 weeks. The mother a 5 para aged 25 was esus-negative with antibodies. The infant was rhesus sitive and the Coombs test was positive. The blood moglobin was 107% (Haldane) Four days after delivery the baby developed head retraction and grunting respiration He died at the age of 5 days.

Necropsy showed jaundice hepatosplenomegaly intra lmonary hæmorrhage, and pale yellow staining of the basal nglia, olives, and medullary nuclei

Summary—Icterus gravis neonatorum with nuclear jaundice

Case 2.—Male Birth weight 2326 g Spontaneous breech delivery at 34 weeks. The mother, a unipara aged 29 was rhesus negative with antibodies. The infant was rhesus positive and the Coombs test was positive The blood hæmoglobin was 24% (Haldane) An exchange transfusion was given but the infant's condition steadily deteriorated and he died at the age of 50 hours

Necropsy showed intense jaundice hepatosplenomegaly intrapulmonary hæmorrhage and diffuse yellow staining of the whole cerebral parenchyma and intense jaundice of the basal ganglia, corpus Luysii cornu ammonis, and flocculus of the cerebellum

Summary—Icterus gravis neonatorum with diffuse cerebral icterus and nuclear jaundice

Case 3—Male Birth weight 1893 g Spontaneous vertex delivery at 34 weeks. The mother aged 19 was a primipara. The infant was jaundiced after twenty four hours but otherwise seemed well until the fifth day when he vomited collapsed suddenly with twitching movements, and died. His blood belonged to group A and was rhesus-positive Coombs test negative

Necropsy showed a deeply jaundiced premature infant, with no lesion in chest or abdomen, and with deep yellow staining of the periventricular white matter basal ganglia, cornu ammonis, vermis and flocculus of cerebellum, inferior olives nuclei in the pons, and nuclei in the floor of the 4th ventricle.

Summary—Premature infant with severe nuclear jaundice

Case 4—Male Birth weight 640 g Spontaneous delivery following sudden onset of labour at 26 weeks The mother was a unipara aged 33 The infant was pale at birth and a gradually deepening jaundice developed. A few convulsions were noted on the second day The child died at the age of 7 days

Necropsy showed an extremely premature jaundiced infant with yellow staining in the periventricular white matter thalami cornu ammonis, mid brain nuclei, nuclei in the floor of the 4th ventricle and medulla, and the inferior olives.

Summary—Prematurity with nuclear jaundice

BIOCHEMICAL METHODS

The following methods were used

Brain pigments were extracted by homogenising the tissue in five volumes of Analar methyl alcohol. The mixture was allowed to stand at room temperature for two to four hours, and a clear supernatant fluid was obtained by centrifuging This was stored at −12°C and a small amount of fine white precipitate which formed was filtered off

For the isolation of pigments from serum 0·18 vol. of saturated ammonium sulphate was added, with mixing followed by 2·5 vol. of absolute ethanol The turbid mixture stood for half an hour at room temperature before being centrifuged The clear supernatant fluid was decanted and stored at −12°C

The quantitative van den Bergh estimation was done in the usual way by adding to sera, or tissue extract, one-half volume of freshly diazotised sulphanilic acid and then three volumes of alcohol The depth of colour was estimated in a photo-electric colorimeter

Pigments from brain and serum were examined by the method of Cole and Lathe (1953) using reverse phase chromatography on silicone-treated kieselguhr and the solvent phases formed from 25 vol. chloroform 25 vol carbon tetrachloride 38 vol. methyl alcohol, and 12 vol 0·025M phosphate buffer It was found convenient to use 6 g of kieselguhr in glass tubes of 1·6 cm. internal diameter and 3 ml. of stationary phase The fractionation procedures reported here were all done under comparable conditions, and the results recorded as sketches of the chromatogram columns, showing the bands of pigment after 15 ml. of the mobile phase had come off the column. The columns of brain extract represented 4 g of brain, and those of serum were equivalent to 1·5 ml.

EXAMINATION OF PIGMENTS

Each of the four brains was treated in the same way but only that of case 2 is described in detail because only minor quantitative differences between the four specimens were observed. When the brain was sectioned at necropsy the deeply stained nuclear areas (9 g) were separated from the remainder of the brain (205 g) The intensely stained, circumscribed, areas probably amounted to less than 10% of the total "nuclear" fraction, because it was impossible to avoid including much unstained material with it The pigments were extracted from both parts of the brain—i.e, the separated "nuclei" and the "remainder" The total amount of diazo reacting material was equivalent to 2 mg of bilirubin per 100 g of the "nuclei" and 0 5 mg per 100 g in the "remainder" Presumably the concentration of pigment was from five to ten times as great in the small pigmented patches

Portions of the extract were taken to dryness in vacuo, and run on to reverse phase chromatograms in the mobile phase After 15 ml of solvent had run through the column, the position and size of the pigment bands from the extracts of the stained "nuclei" and of the "remainder" were noted and sketched (fig 3*a* and *b* respectively) Each chromatogram showed two yellow bands, the upper slowly moving band being substantially larger and much more intensely stained than the lower fast moving band In this respect the same general pattern was observed in both chromatograms, but a difference was observed in the size and tint of the upper band, which was wider and more deeply coloured on the chromatogram of the nuclear fraction

As an aid in identifying these bands 50 μg of bilirubin was run on another chromatography column under the same conditions, producing the result shown in fig 3*c* The bilirubin took up a position intermediate between the two bands from icteric brain However, when bilirubin was added to an extract of this brain, and the combined material was run on a column, the result (fig 3*d*) was similar to that of the nuclear extract (fig 3*a*), the bilirubin moving with the slow upper band, which it intensified

It was concluded that on the chromatogram the predominant pigment of brain icterus behaves identically with bilirubin in the presence of brain extract

To determine their van den Bergh reactions the pigments were eluted from the chromatography columns They gave positive diazo reactions, that of the upper band being much stronger than that of the lower band. This was in agreement with the relative depth of yellow

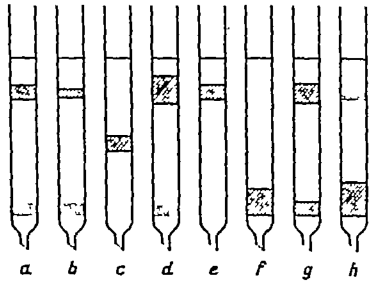

Fig 3—Appearance of standard chromatography columns

a, extract of "nuclear" portion of icteric brain, showing prominent slowly moving upper band of indirect reacting pigment, and faint lower band of fast-moving direct reacting pigment
b, extract of "remainder" of icteric brain
c, standard of bilirubin
d, bilirubin added to "nuclear" portion of icteric brain
e, bilirubin added to extract of normal brain
f, direct-reacting bile pigment added to extract of normal brain
g, extract of serum removed during exchange transfusion of infant with hæmolytic disease, showing greater proportion of lower fast moving direct reacting pigment than in icteric brain (*a*)
h, extract of serum from surviving jaundiced infant without hæmolytic disease, showing great predominance of lower fast moving direct reacting pigment.

For comparison, extracts were made of the brains of two babies who died of rhesus incompatibility at the ages of 3 and 15 hours There was no visible staining of the brain tissue The bile pigments in the serum of one of these babies were equivalent to 6 3 mg of bilirubin per 100 ml The colour of the brain extracts confirmed the lack of tissue staining The brains of five stillborn babies were also examined without finding any significant amount of pigment.

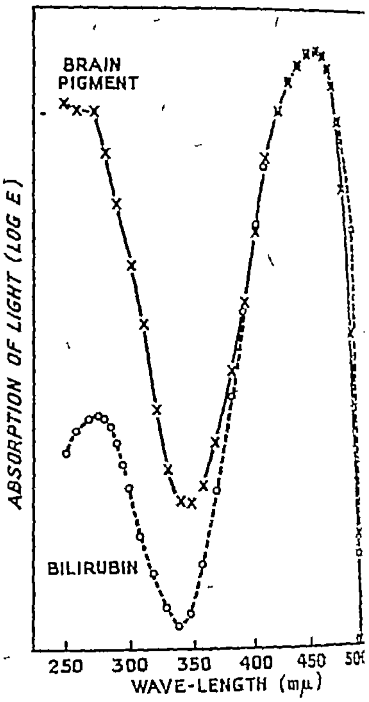

Fig. 4—Ultraviolet and visible spectrum absorpt curves of standard bilirubin and of brain pigm

Visual and Ultraviolet Absorption Curves

The character of the pigment present in brain icter was pursued further by studying its absorption cur This was examined in the solvent as it came off t partition column For comparison under identical co ditions a standard of bilirubin was also run through column In fig 4 the curves of the two pigments a compared They are almost identical throughout t visible range (400–510 mμ), but in the ultraviolet ran they differ, the brain pigment having a noticeably grea absorption This ultraviolet absorption, in excess of th of bilirubin, has also been observed when bilirubin h been put on the chromatogram with normal unstain serum extract, and in fact the corresponding eluates serum alone absorb in this region Accordingly t difference from bilirubin may be attributed to t materials which are eluted from the column with bi rubin In other respects the absorption characteri of the brain pigment are those of bilirubin, and they sh identical peaks at 454 mμ.

Pigments in Serum

Since staining of the brain takes place only when the is an excess of pigments in the serum, it may be assum that the brain pigments have their immediate origin the blood stream Hence it seemed important to obta information about the types of pigment to which t blood brain barrier is exposed In erythroblasto fœtalis it is possible to examine these pigments in t blood removed at exchange transfusion, and this w done in 9 cases by the same techniques as were appl to brain extracts It would have been preferable t compare brain pigments and serum pigments from t same patients, but in recent months only 1 pati undergoing exchange transfusions has died, and no bra icterus was present in this instance

The chromatographic examination of the 9 ser specimens from exchange transfusions revealed that upper slowly moving pigment, which is bilirubin, pr dominated in 8 cases, but there was a considerabl ation in the amount of the lower fast moving bile nent which reacts directly in the van den Bergh . In one of the exchange-transfusion sera this latter nent was present in larger amounts than was bilirubin, in several cases appreciable quantities were present 3g) Since this difference in pigment composition ween brain and serum suggested a selective con tration of bilirubin in the pigmented areas of brain er evidence of discrimination between these pigments looked for in tissue extracts

he sera of jaundiced newborn babies do not all show same proportion of pigments as was found in the d removed by exchange transfusions. In particular fast-moving direct reacting bile pigment may be far e abundant Recently we have seen 3 jaundiced new n infants of this type all having greatly increased unts of bile pigments in the serum (one had 50 mg 100 ml) but bilirubin was responsible for only a or part of this increase as a chromatogram of serum act showed (fig 3h) These babies survived.

Bilirubin retaining Lipid

n observation that appeared to throw some light on staining of brain tissue was the slowing of the rubin band on the column when an extract of icteric n was run simultaneously (fig 3*d*) The same effect demonstrable with extract of unstained brain . 3e) and with extracts of serum Since these chromato ms are partition columns the retardation of bilirubin t be due to either a relative increase in the volume of stationary phase or to an increased concentration in phase The first possibility was excluded by mining the effect of brain extract on the movement bilirubin and an eosin dye. Without brain extract y move at an almost identical rate In its presence ever, bilirubin is held back without the movement the eosin being affected. There is thus some specificity the affinity of brain extract for bilirubin

Whether the fast-moving direct-reacting bile pigment serum would be retarded was next determined. Some this pigment was obtained from the serum of an adult h obstructive jaundice and was added to an extract brain. Its rate of movement on the column (fig 3*f*) wed that the bilirubin retaining material had no nity for the direct-reacting bile pigment.

It was of some interest to see whether there were ater amounts of this bilirubin retaining material in mented than unpigmented brains, and more in nuclear ' areas than the remainder ' No differences re found, but this might be due to the method of imation, which is only semiquantitative, and to the ficulty of getting predominantly nuclear materials for aly From the position of the bilirubin retaining aterial on the columns a lipid character may be inferred, t large amounts of brain lecithin, cephalin, cerebroside, olesterol and neutral fat were inactive

DISCUSSION

In this survey *of cases from two hospitals it was* nd that jaundice of the brain occurred in about 1 per 00 live births and in almost 9% of neonatal deaths ere are certain pronounced differences between the o groups of infants who show icterus of the brain e first group is associated with hæmolytic disease of newborn the affected infants are usually mature, less the pregnancy has been deliberately interrupted ause of the hæmolytic disease. Their mothers are ost invariably multiparous since they most commonly elop iso immunisation as the result of a previous gnancy The infants may be jaundiced at birth or elop jaundice shortly afterwards. The greatest rtality is on the third day

By contrast the patient in the second group of cases is ally a premature infant. There is no evidence of rhesus iso immunisation in the mother most of the mothers in our series were rhesus positive. The mothers are often primiparæ, as this series shows since previous sensitisation is apparently not essential to the development of the lesion in this group The greatest mortality in this group is on the seventh day

In spite of these pronounced differences in the pathogenesis of icterus of the brain in the two groups of patients the general distribution of the pigment in the brain does not appear to differ from one group to the other

The brain pigment from 4 newborn infants representing both types of case has been examined. From a study of the diazo reaction, the chromatographic behaviour and the absorption spectrum we conclude that the brain pigment of each type of case is bilirubin.

Schmorl (1904) is sometimes cited as saying that the pigmentation in brain icterus was not due to bilirubin, and a similar argument has been advanced by Pickles (1949) It must be recalled that at the turn of the century little was known of the different bile pigments and as a result Schmorl spoke of jaundice being due to ' bile pigment He observed that the organs of newborn infants affected with nuclear jaundice remained yellow when preserved in formalin, whereas the organs from other cases of neonatal jaundice turned green. He concluded from this that the nuclear pigmentation was not due to ' bile pigment. However evidence that bile pigment ' was more complex was introduced a few years later by van den Bergh and Muller (1916) who noted that some icteric sera gave a direct diazo reaction and others gave an indirect reaction. These pigments have been separated by Cole and Lathe (1953) and it is clear now that the direct-reacting pigment, which moves fast on a chromatographic column, and predominates in obstructive jaundice is not bilirubin The indirect reacting pigment, characteristic of hæmolytic jaundice moves slowly on a column and is bilirubin. It has been known for a long time (van den Bergh 1918 Andrewes 1924) that the direct-reacting bile pigment is particularly easily oxidised to green derivatives, whereas the indirect-reacting pigment, now known to be bilirubin, is more stable Thus in the light of our present knowledge Schmorl s original observations are in keeping with the identification of the brain pigment as bilirubin

The claims of Bevis (1952a) that the yellow brown pigment of liquor amnii is mesobilifuscin and (Bevis 1952b) that this is also the pigment of icteric brain are difficult to assess without experimental evidence. In unpublished experiments we have fractionated samples of liquor amnii from patients with hæmolytic disease and found not one but several pigments. Unfortunately a specimen of mesobilifuscin has not been available for chromatographic comparison with the pigments from liquor amnii or for absorption studies in relation to brain pigment The absorption spectrum of mesobilifuscin (Meldolesi et al 1939) bears little resemblance to that of bilirubin. Moreover the nature of mesobilifuscin is very *obscure five types having been described by Siedel* et al. (1948) These workers who have been largely responsible for the studies of bilifuscins, state that mesobilifuscin does not give a diazo reaction (Siedel and Möller 1939) Unlike Bevis (1952b) we have found that the brain pigment reacts positively as does bilirubin.

In contrast to the brain extracts, in which bilirubin greatly predominated, extracts of serum from other cases of hæmolytic disease had a larger proportion of the direct-reacting bile pigment. Thus the brain seems to have a selective attraction for bilirubin. This possibility is supported by the demonstration that brain tissue contains a bilirubin retaining lipid, and that this material has no affinity for the direct-reacting bile pigment.

It is clear that the occurrence of extreme jaundice and of greatly increased quantities of bile pigments in the serum is not in itself necessarily damaging to the neonatal brain This is illustrated by the three newborn infants in whose serum the levels of total bile pigments were very high (up to 50 mg per 100 ml according to the diazo reaction) However, the amount of bile pigment present in the form of bilirubin was relatively small (fig 3*h*) From the survival of these babies it may be assumed that the direct reacting pigment did not affect the brain In a similar way it is possible to explain the anomaly that icterus of the brain does not appear in the more pronounced jaundice of adult patients with obstruction or in congenital atresia of the bile ducts in the newborn In these conditions the main pigment to which the brain is exposed is not bilirubin but the direct reacting bile pigment

Thus the relative absence of the direct-reacting bile pigment from icteric brain, together with the absence of brain icterus in clinical jaundice due to this pigment, serves to direct attention to the rôle of bilirubin in the production of brain icterus It follows, too, that the conversion of bilirubin to the direct reacting pigment tends to protect the neonatal brain from icterus There is much evidence from other sources that this change is made by the liver, and reduced liver function may contribute to the development of brain icterus in both types of case Indeed, a defect of this conversion may be the primary factor leading to the brain icterus of premature babies, in whom no increased production of bilirubin has yet been demonstrated. This would be consistent with the longer survival of the premature baby than of the baby with hæmolytic disease

These studies emphasise the crucial importance of bilirubin in the development of brain jaundice It now seems to be necessary to determine whether a high level of bilirubin has a direct toxic effect, or whether some additional factor—e g, cell damage, and altered permeability of the blood brain barrier—is a prerequisite for the development of icterus of the neonatal brain

Summary

The incidence of brain jaundice in neonatal infants in two large maternity hospitals has been determined.

About a quarter of the cases are associated with prematurity and clearly distinguished from the rest, which are associated with hæmolytic disease

The differences between these two groups of cases have been analysed

The pigment responsible for the staining has been extracted from the brains of two infants in each group The pigment of icteric brain in the premature infants is identical with that in the infants with hæmolytic disease It is bilirubin A bilirubin retaining lipid has been shown to be present in the brain

Direct reacting bile pigment is largely absent from the icteric brains but is present in various amounts in the serum of babies with hæmolytic disease This pigment is not concentrated by the bilirubin-retaining lipid of brain in vitro and it does not stain the brain tissue

Emphasis is laid on the rôles of bilirubin and of the liver, which may protect the brain of the newborn infant by converting bilirubin to direct reacting pigment

We wish to acknowledge the help that has come from many discussions with our clinical and laboratory associates, especially Dr John Murray We are grateful to Prof J H. Dible, of the Postgraduate Medical School of London, and Prof J McClure Brown, of the Institute of Obstetrics and Gynæcology, Hammersmith Hospital, for access to clinical and pathological records and material.

DERMATOLOGY, LONDON

THRUSH of the vagina and vulva, caused by the yea like fungus *Candida albicans*, is well known, but les degrees of vulvovaginitis due to this organism ar probably inadequately recognised Investigations int the significance of vaginal yeasts have not been made i Britain, and surveys made elsewhere have often bee uncritical For these reasons we have assessed th incidence and significance of vaginal yeasts in patien attending four family-planning clinics in North Londo and Hertfordshire

Material and Methods

500 patients were examined All were attending th clinics for the first time, but 56 had attended a similar clinic on previous occasions and were regular users of contraceptive diaphragm New registrations include in the trial, on any one day, could not exceed 6, becau of the extra time required for questioning and for tak specimens New patients attending these clinics nev exceeded 10 in an evening and were often fewer than Postnatal clinics and general practitioners referred 1 patients, for instruction in birth control for medic reasons not pertaining to disease of the urogenit tract, the remaining 308 patients attended of their ow initiative None of the patients was known to be sub fertile, and of the 476 married ones 388 were parou Their ages ranged from 17 to 45 years The patient therefore comprised a selected section of the population although they included representatives from all five o the Registrar General's social classes (General Regist Office 1951)

One person took all the histories and made all th clinical observations throughout the investigation Mimeographed sheets were used for recording persona and medical histories, clinical observations, and laboratory findings The laboratory work was done withou knowledge of the clinical findings The data from the sheets were transferred to punch-cards for analysis.

HISTORY

Each patient was asked the same questions Th routine clinic questions dealt with general health an gynæcological, obstetrical, marital, and contracepti

histories. Most patients did not volunteer information about gynaecological symptoms so it was necessary to elicit them by direct questioning Questions concerning pruritus vulvæ were the following:

(1) Have you ever had itching?
(2) Was this during pregnancy?
(3) Have you had itching during the last month, and is it present now?

Pruritus was recorded as mild unless the patient emphasised its severity It was recorded as present now, if the answer to either of questions (3) was 'Yes.' Parous patients were asked whether oral thrush had occurred in their children other questions dealt with douching and intravaginal tampons

CLINICAL SIGNS

These were recorded as soon as the patient had been examined and the laboratory material obtained. The presence or absence of vulval and vaginal inflammation was noted. The quantity of secretion or discharge was assessed as profuse moderate or scanty 'Moderate' and 'scanty' were considered to be within normal limits, but 'profuse' was regarded as pathological Its appearance was described as mucous, mucopurulent curdy or bloodstained The patient's description of the discharge was also recorded but bore little relation to our observations. For a clinical diagnosis of thrush the criteria were vaginitis and patchy white curdy, and rather adherent discharge, sometimes extending to the vulva and cervix. Cervicitis erosion, and ectropion were recorded with a diagram

COLLECTION OF LABORATORY MATERIALS

500 vulval and a similar number of vaginal swabs were examined With the patient in the lithotomy position a swab (previously soaked in Sabouraud's broth) was swept over the outer and inner surfaces of the labia minora and round the introitus. A sterile Cusco's speculum, without lubricant, was next inserted, the cervix was exposed and a second swab similarly soaked was passed round the outer surface of the cervix and into the posterior fornix. Finally, a pipette fitted with a rubber teat was inserted and 1 ml. of sterile 0 85% saline solution was ejected into the fluid in the vaginal pool After mixing some of this fluid was aspirated. Premarital patients were occasionally advised and in these cases, if the hymen was insufficiently dilated, the second swab was guided through a small sterile glass tube instead of through the speculum

LABORATORY PROCEDURES

The aspirates from the vaginal pool were examined within three hours for the presence of *Trichomonas vaginalis* Low power microscopy was used on the whole area of two wet preparations of each sample Since they could not be examined until morning the swabs for yeast investigation were stored overnight at 2°–5°C Quarter plates of Sabouraud's dextrose agar gentian violet bile salt medium (Littman) and penicillin streptomycin blood-agar (30 units of each antibiotic per ml. of medium) were inoculated from each swab Finally, the swab was used to make as thick a smear as possible over a circular area of half inch diameter on a slide. The smear was stained by Gram's method and examined for yeasts and pus cells before the results of culture were known. Each plate was incubated for forty-eight hours at 37°C and the amount of yeast growth was recorded as 0, 1–50 colonies, + ++ or +++ Throughout the survey the assessment of growth was made by one person. For identification a representative yeast colony was picked from each plate; where more than one type of colony was present each type was sampled Bacterial contaminants were excluded by plating on blood agar, and the yeast colonies were identified by the following cultural properties:

(1) The presence or absence of mycelium and chlamydospores, determined by deep streak culture in corn meal agar incubated at 22°C for forty-eight hours. When no mycelium was produced in corn meal agar potato water was inoculated

(2) The production of acid and gas in peptone water containing 2% glucose, maltose sucrose, and lactose

(3) The assimilation of carbohydrates (glucose maltose sucrose lactose and galactose) and nitrogenous compounds (ammonium sulphate potassium nitrate urea and asparagine by an auxanographic technique

(4) The production of ascospores on carrot slopes

Techniques for the differentiation of yeasts are fully described by Lodder and Kreger (1952) and a brief reference to the laboratory diagnosis of candida species is made by Riddell (1951) The production of chlamydospores is discussed by Gordon et al (1952)

Results

INCIDENCE OF YEAST LIKE FUNGI

Table I sets out the incidence of yeast-like fungi among the 57 patients from whom positive cultures were obtained *C albicans* was found in 38 of these the other yeasts comprised at least five species Most of the patients yielded positive cultures from both vulval and vaginal swabs, but 6 gave positives only from the vagina and 8 only from the vulva Of these, 4 and 5 respectively yielded cultures of *C albicans*

TABLE I—YEAST LIKE FUNGI IN VULVAL AND VAGINAL SWABS FROM 500 PATIENTS

Species	No of patients
Candida	
C albicans	38
C krusei	3
C tropicalis	3
C parakrusei	1
C mycoderma	1
Unclassified	3
Torulopsis (Cryptococcus):	
T glabrata	7†
Unclassified	2
Total	57

Including 6 cases of thrush.
† Including 1 patient also harbouring *C albicans*.

In smear preparations various species of yeast were found to be indistinguishable and the smear technique was shown to be useless as a guide to the presence of *C albicans* Although 9 swabs gave smears positive for yeasts which failed to grow in culture, smears indicated the presence of yeasts in only 66 of 102 swabs from which yeasts were ultimately grown

Of the 54 swabs giving profuse cultures 51 showed yeasts in the smear but the 48 swabs giving poor or moderate growths yielded only 15 positive smears (table II) For *C albicans* alone similar figures were obtained from 32 swabs giving profuse cultures positive smears were obtained in 20 instances; but 35 swabs which produced moderate or poor cultures gave positive smears in only 13

Sabouraud's dextrose agar as used in most laboratories was as satisfactory for primary isolation of yeasts as the other two media used in this investigation

TABLE II—COMPARISON OF CULTURES AND SMEARS FROM 1000 VULVAL AND VAGINAL SWABS

Species	Culture +++ and ++		Culture + and 1–50 colonies		Culture negative	
	No	With positive smear	No.	With positive smear	No.	With positive smear
C albicans	32	29	35	13	898	9
Other yeasts	22	22	13	2		
Total	54	51	48	15	898	9

TABLE III—RELATIONSHIP OF PRURITUS TO YEASTS

Pruritus	No of cases	With C albicans	With other yeasts
Severe	11	6	1*
Mild	72	7	5
Past history	139	8	5†
Absent	278	17	9
Total	500	38	20†‡

* *C albicans* also isolated from this patient
† Includes 1 patient in whom trichomonads were also present
‡ Includes 1 patient from whom *C albicans* was isolated

OTHER FINDINGS

Thrush was seen in 6 patients, and in each case *C albicans* was grown from both vulval and vaginal swabs In 4 of these patients both swabs produced heavy growths, but in the other 2 only moderate growths developed Yeasts were obvious in smears from 5 of these patients, but the 6th had scanty yeasts in the vulval smear and none in the vaginal one In the presence of an active infection with *C albicans* the greater reliability of culture technique is confirmed

Pruritus —Table III gives the incidence of pruritus and its relationship to the presence of *C albicans* A significant incidence of *C albicans* was found only in relation to severe pruritus (P<0 001)

Vulvitis, Vaginitis, and Cervicitis —Patients with vulvitis or with vaginitis harboured *C albicans* significantly more often than patients without these signs (P<0 001), but there was no significant difference in the incidence of "other yeasts" (table IV) Of 107 patients with vulvitis or vaginitis 21 harboured yeasts, of which 18 were *C albicans* Of 393 patients without these signs 37 harboured yeasts, of which 20 were *C albicans* There was no significant relationship between cervicitis and the presence of any yeasts

Vaginal Discharge —50 patients had a profuse discharge Thrush, present in 6 patients, was accompanied by profuse discharge in 3, and by moderate discharge in the other 3 There was a significantly higher incidence of *C albicans* in patients with a profuse discharge than in those with moderate or scanty discharge (P<0 05) (table V) *C albicans* accompanied a "curdy" discharge significantly more often than other yeasts (P<0 01)

Pus and Epithelial Cells in Smears —The numbers of pus cells were not significantly related to the cultural isolation of any yeasts

Duration of Marriage and of Parity —No significant relationship to either of these factors was observed 24 premarital women were examined, candida species were not isolated from any of them

Douching and Intravaginal Tampons —The incidence of *C albicans* was significantly higher in patients who douched regularly than in those who did not (P<0 05), no relationship could be shown between the incidence of yeasts and the use of intravaginal tampons (table VI)

TABLE IV—RELATIONSHIP OF VULVITIS, VAGINITIS, AND CERVICITIS TO YEASTS

Group	No of cases	With C albicans	With other yeasts
Vulvitis and vaginitis			
Vulvitis alone	44	6	0
Vaginitis alone	27	5	1
Vulvovaginitis	36	7	2*
Absent	393	20	17†
Total	500	38	20*†
Cervicitis			
Severe	64	6	2
Mild	174	13	5†
Absent	262	19	13
Total	500	38	20†

* Includes 1 patient from whom *C albicans* was isolated
† es 1 patient in whom trichomonads were also present.

Thrush in Infants —No correlation was found between the presence of *C albicans* and a history of thrush in the last infant The mothers' replies to direct questions were the only criteria of infantile thrush.

Social Status and Standard of Personal Hygiene —No significant relationship was observed between the factors and the presence of yeasts

Incidence of Trichomonads —Trichomonads were found in the secretions of 9 patients, from 1 of whom a yeast (*C tropicalis*) was grown None of these complained of pruritus during the past month, and only 1 had a profuse discharge There was, however, evidence of vulvovaginitis in 4 patients and of cervicitis in 3 None practised douching

Discussion

The incidence of yeasts in the vulvæ and vaginæ of this group of non-pregnant women was 11 4% (10 3% if thrush is excluded) Figures of other investigators for similar groups range from 7 3% (Weinstein and Wickerham 1938) to 15% (Carter and Jones 1937, Plass et al 1931) There is considerable evidence that yeasts occur more often in pregnant women, and figures for this group range from 25% (Weinstein and Wickerham 1938, Woodruff and Hesseltine 1938, Raurumo 1950) to 43% (Carter et al 1940) The species isolated in this survey are similar to those in other reports It is noteworthy that *C stellatoidea*, the vaginal strain described by Jones and Martin (1938), was not found among the 102 cultures isolated Rauramo (1950) also failed to isolate this organism from his cases The incidence of *C albicans* alone was 7 6% (6 5% if thrush is excluded) These figures are comparable with those obtained for similar groups by Negroni (1935) and Fisher and Arnold (1936) Their estimates of the incidence in pregnant women were three or four times as great

TABLE V—RELATIONSHIP OF VAGINAL DISCHARGE TO YEAST

Group	No of cases	With C albicans	With oth yeasts
Vaginal discharge			
Profuse	50	7	4*†
Moderate or scanty	450	31	16
Total	500	38	20*†

Not curdy	449	26	18
Total	500	38	20

* Includes 1 patient from whom *C albicans* was isolated.
† Includes 1 patient in whom trichomonads were also present.

The infectivity of *C albicans* (syn *C pinoyi* and *C* *metalondinensis*) cultures inserted into the vaginæ of both pregnant and non-pregnant patients was shown by Hesseltine et al (1934) and Bland et al (1937), using other candida species for controls Bland et al showed that pruritus and increased discharge began twenty-fou to ninety six hours after inoculation In the presen study close associations were found between the presen of *C albicans* on the one hand, and vulvovaginit discharge (both profuse and curdy), and severe prurit on the other However, 14 of the 38 patients harbouring *C albicans* had neither signs nor symptoms This suggests that infection may be completely latent, mildly inflammatory (with or without symptoms), or the cause of full clinical thrush with symptoms of variable severity The response of the patient to the presence of *C albicans* is governed by factors which are at presen unknown

VI—RELATIONSHIP OF DOUCHING AND INTRAVAGINAL TAMPONS TO YEASTS

Group	No. of cases	With C albicans	With other yeasts
ng			
than once monthly	60	10	0
than once monthly	67	7	0
r	373	21	20
otal	500	38	20
ginal tampons			
	128	5	1
used	372	33	19
otal	500	38	20

ical assessment of purulent discharges was often ading Epithelial cells in smears from these often y exceeded pus cells in number and the latter were imes absent. C albicans did not tend to produce lominantly leucocytic exudate

ture for C albicans was positive in 6 of the 11 its with severe pruritus and all 6 showed profuse h. Of 72 patients with mild pruritus only 4 uding 3 cases of thrush) grew C albicans Smears s cells and trichomonads did not indicate bacterial otozoal infections The lack of correlation between pruritus and isolation of this yeast could possibly ie to the technique of direct questioning Very degrees of pruritus caused by the mechanical s of clothing or dried secretions, may thus have been led.

Family Planning Association clinics, patients do not teer information about discharges or pruritus, and ently very few had even consulted their general tioners. It appears that minor discomfort is ted by many women without medical advice being it.

is attitude in women with mild symptoms and nal signs, and the complete absence of symptoms igns in others harbouring C albicans, may prevent ynæcologist from taking special precautions as he d do in a case of obvious thrush If adequate aseptic iques are not observed, the organism can clearly be ferred from patient to patient, and this hazard is derably greater in the case of pregnant patients. ar comments in respect of trichomonads have been by Donald (1952) Where lack of other facilities sitates reliance on antiseptics it must be remembered C albicans is resistant to some accepted bacterial eptics customarily used in many gynæcological s.

i interesting correlation exists between regular hing and the presence of C albicans The douching t appears unrelated to the presence or absence of itus Probably a predisposition to infection results mechanical or chemical trauma and disturbance of normal bacterial flora Antibiotics are known to ur the growth of fungi by disturbing the balance of ai commensal bacteria and it is conceivable that hing may do the same.

ie results of laboratory diagnosis show three distinct

) Only two thirds of the yeasts found by culture may be bicans

) Species of yeasts cannot be identified from smears or ial appearance.

) Smears alone may show the presence of yeasts in only it two thirds of patients whom culture shows to be ouring C albicans

his survey shows that in clinically recognisable thrush h smears and cultures are positive. In such cases tment would probably be started on clinical grounds e. When cases of pruritus and leucorrhœa without frank thrush are being investigated, a smear or a single culture may be misleading C albicans may be reported when subsequent fermentation reactions would reveal some other species of yeast. If the gynæcologist suspects that a clinical abnormality is causally associated with the presence of C albicans, the following procedure is suggested

(1) Swabs of vulva and vagina should be cultured on Sabouraud's dextrose agar

(2) Pure cultures of yeasts obtained should be examined for ability to ferment peptone water containing 2% of sugar (glucose maltose, sucrose, and lactose) C albicans ferments glucose and maltose, forming acid and gas and sucrose forming acid only 2% sugar solutions are generally considered preferable but the 1% solutions available in most laboratories may be used

(3) Identification is completed by ascertaining the ability to produce chlamydospores. Some strains, however do so with difficulty

Animal pathogenicity tests are unnecessary in routine work since there is no reliable evidence of the existence of different degrees of experimental pathogenicity of strains of C albicans

Summary

An investigation was made to determine the incidence of vaginal yeast-like fungi in patients attending four family planning clinics

Yeasts were cultured from 57 of 500 patients 38 of these patients harboured Candida albicans and the remainder at least 5 other species.

The superiority of cultural methods over the examination of smears is illustrated

In the 6 cases of clinically recognisable thrush smears were all positive and C albicans was cultured.

Patients with severe pruritus, vulvitis vaginitis, or profuse and curdy discharge harboured C albicans significantly more often than those without these symptoms and signs.

The incidence of C albicans was also higher in those who douched regularly

No significant relationship was found between the presence of yeasts and the social status or standard of personal hygiene of the patient, the duration of marriage, parity a history of thrush in the last infant the use of intravaginal tampons or the presence of cervicitis,

The hazards of cross infection by C albicans are discussed

Recommendations are made on laboratory diagnosis

We wish to thank all those in clinics and laboratories who helped in this study The statistical advice of Mr B Benjamin of the General Register Office, is acknowledged with gratitude as also is the technical assistance of Miss Y M Clayton, of the Institute of Dermatology

Although many factors have been implicated in the production of hydrocephalus, it has not been reported previously that a deficiency of vitamin A in the mother may determine the development of hydrocephalus in her offspring

The association of vitamin-A deficiency with xerophthalmia and changes in other epithelial tissues has long been recognised Observations on laboratory and domestic animals have also provided data which indicate that lesions of the central nervous system may arise as a concomitant of vitamin-A depletion Various explanations of these nervous lesions have been advanced The most popular view appears to have been that put forward by Mellanby (1938), who claimed that overgrowth of bone is the factor that injures the nervous system Unfortunately most of the experimental studies on the effect of vitamin A deficiency have suffered from an incomplete examination of the central nervous system The available information on the effects of vitamin-A deficiency in domestic animals is confined mainly to the symptoms and to examination of the peripheral nerves

The present study arose from an investigation by one of us (G E L) on the effect of subclinical vitamin-A deficiency on fertility and growth in a strain of inbred rabbits It was noted that, in some of the young born to does deficient in vitamin A, symptoms of nervous disorder appeared at various times after birth Radiological examination suggested that the underlying condition might be hydrocephalus, and this diagnosis proved to be correct

Experiments and Methods

16 young rabbits aged from two weeks to two months, were obtained from five different litters In three litters all the young (5, 5, and 3) have been examined, in the other two litters surviving young, not yet showing symptoms, await further investigation All 16 rabbits showed signs of lesions of the nervous system 14 were killed in this investigation and 2 others died from natural causes and were later examined

3 of the does belonged to an inbred strain of stock rabbits and were mated to males of the same strain, 1 of the other 2 females was from the inbred strain but belonged to a line which had been separated out for colour some years previously the remaining doe was an outbred animal and was mated with an outbred male, both of them being quite unrelated to the other strain

All 5 does had received a diet which contained no detectable carotene (provitamin A) for fourteen weeks before mating 1 received orally a small amount of vitamin A in arachis oil (150 i.u. per kg body weight per week) No supplement of vitamin A was given to the young after weaning The rabbits used as controls were progeny from similar does receiving the same diet with the addition of a supplement of vitamin A

Attention was first drawn to the condition by the appearance of signs of nervous disorder and a curious retraction of the head in one litter Clinical examination revealed signs of paralysis, particularly in the hind limbs

Subsequent investigation included radiological examination of the skull and vertebral column, and the injection of 'Dag' colloidal carbon into the ventricles during life Coronal sections of the head were prepared after deep freezing, the hinder part of the cerebellum and lower end of the fourth ventricle were exposed by cervical laminectomy, and frozen sections made transversely through the mid-brain and cerebral aqueduct at all levels were prepared and stained In addition the optic nerves and their surroundings were examined in all the animals

Numerous control rabbits of comparable ages were examined at every stage of the investigation

Findings

Radiography revealed an enlargement of the calvarium of the skull and a "beaten silver" appearance of the bone similar to that observed in human hydrocephalus. This finding led to a tentative diagnosis of hydrocephalus and was largely responsible for determining the methods by which the material was afterwards treated

In all the rabbits examination of the coronal sections of the cerebral hemispheres revealed gross dilatation of the lateral and third ventricles In some specimens the cortex and white matter were reduced to such an extremely thin layer lining the interior of the skull that it was surprising to find such a condition compatible not only with life but even with comparatively few clinical signs of hydrocephalus (fig 1) In 1 rabbit the brain tissue had herniated through the skull and formed a slight swelling under the skin

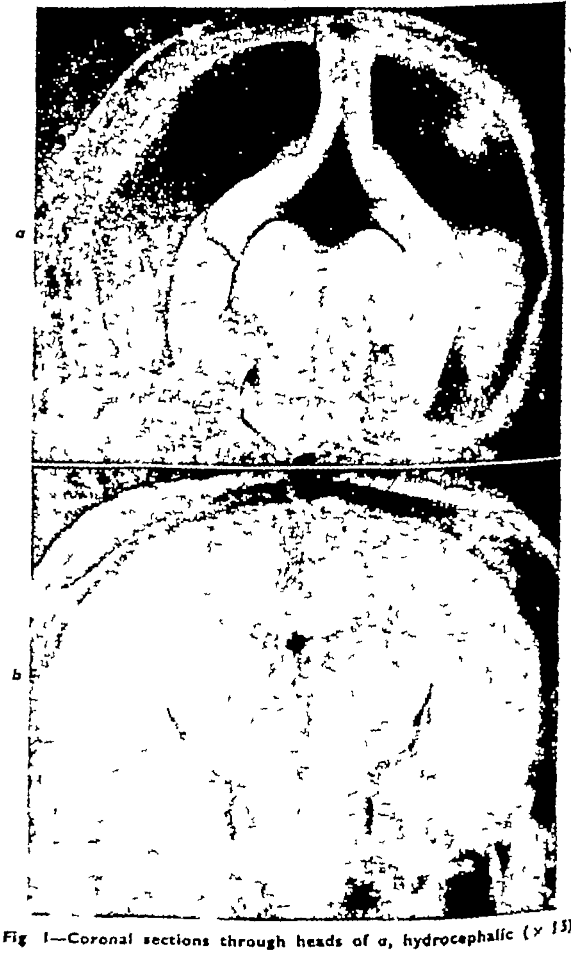

Fig 1—Coronal sections through heads of a, hydrocephalic (× 1½) and b normal rabbit (× 2½)

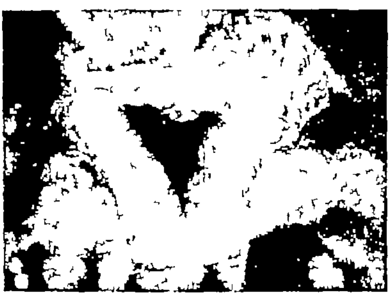

Fig. 2—Constriction of optic nerves in region of optic foramina of hydrocephalic rabbit (× 7 5)

Laminectomy showed that the cerebellum had herniated through the foramen magnum but the fourth ventricle appeared normal, and this was confirmed by subsequent microscopy In those animals in which colloidal carbon had been injected into the ventricles there was no sign of any carbon in the fourth ventricle, although the dilated lateral and third ventricles were well filled On further exposure of the brain and cranial nerves it was found that both optic nerves exhibited well marked constrictions at the optic foramina (fig 2) In none of the specimens was any deformity of the foramen magnum or of the base of the skull observed, nor was there any evidence of meningitis

The examination of *transverse sections through the* cerebral aqueduct revealed a well marked stenosis at the level of the superior colliculus Fig 3 shows transverse sections through the aqueducts of *a*, hydrocephalic and *b* normal rabbits The cross-sectional area of the lumen of the aqueduct in the hydrocephalic rabbit was 0·16 sq mm. and that of the normal rabbit 0 71 sq mm Above this level the lumen of the aqueduct was dilated and distal to the *constriction the aqueduct appeared* normal The colloidal carbon did not pass beyond the constriction.

In the absence of any figures for the size of the aqueduct in the normal rabbit comparison was made with sections through various comparable levels in control rabbits of corresponding age and size As a result of these investigations it was concluded that the signs of nervous disorder in these vitamin A deficient rabbits could be attributed to hydrocephalus produced by stenosis of the cerebral aqueduct. Further there appeared to be a causal relationship between the vitamin A deficiency and the development of the aqueductal stenosis.

Discussion

These findings introduce an entirely new concept of the ætiology of some forms of hydrocephalus.

The question naturally arises whether the hydrocephalus in these rabbits could be explained by a genetic factor Congenital hydrocephalus attributed to a genetic factor has been reported in mice (Grüneberg 1043, Clark 1034) It must be presumed that mutation was responsible for the appearance of these strains although no information is available about their diet. 14 of the present 16 rabbits belonged to a strain separated by Dr John Hammond in 1024 and inbred since then The characteristics of this strain have been carefully documented, and there is no record of spontaneous congenital hydrocephalus. It is considered that the finding of hydrocephalic young in five litters from different matings rules out the possibility of a mutation having been responsible for the condition Further of numerous control rabbits from the same strain none has ha hydrocephalus.

Because of its economic importance much attentio has been directed to the effects of vitamin A deficiency f farm animals

As long ago as 1910 Hart et al. noted that pigs fed o a deficient diet developed paralysis of the limbs. A necropsy the vertebral canal contained a considerab quantity of fluid, and in the spinal cord the anterior hor cells were shrunken, surrounded by fluid and appeared to b under pressure For some reason, however the brai though removed was not examined.

Mellanby working mainly on puppies, has contribute largely to the study of the effect of vitamin A deficienc on the nervous system. He has concluded that disorganisatio of bone formation leading to overgrowth is responsible fo compression of the optic nerves and the consequent papil œdema (Mellanby 1938) The results of the present investiga tion suggest that the signs of papillœdema and the compressio of the optic nerves observed by Mellanby may well have bee the consequences of the hydrocephalus which he note (Mellanby 1941) but to which he does not seem to hav attached much importance

The view that abnormal bone growth is responsible for th production of nervous lesions has been accepted by Moor (1930) as the explanation of night-blindness, papillœdem and optic atrophy in calves fed on a diet deficient in vitamin A

Moore et al. (1935) also observed that such calves ha partial paralysis and held their heads in a peculiar position At the same time they considered that the pressure of th cerebrospinal fluid (C.S.F) was raised. Moore and Sykes (1941 reported that there was a progressive increase in the pressur of the C.S.F as the condition developed They observe also that in 1 calf the ventricles were dilated, but apparentl they did not attach any significance to this observation nor do they seem to have reached any definite conclusion about the cause of the increased pressure of the C.S.F Unfortunately in none of these investigations was a detailed histological examination of the brain reported and it i therefore impossible to say whether Moore and Sykes wer dealing with the effects of aqueductal stenosis.

Many other investigators have commented on th incidence of lesions of the nervous system in animal subjected to experimental vitamin A deficiency and i some instances have noted herniations of the brain such as are known to occur in hydrocephalus in man (Wolbach and Bessey 1941) The clinical course of the disease reported in many of these accounts accords closely with the picture observed in the present experiments and

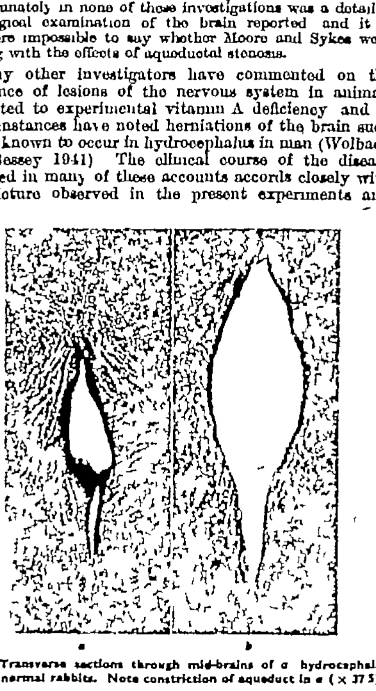

Fig. 3—Transverse sections through mid-brains of *a* hydrocephalic and *b* normal rabbits. Note constriction of aqueduct in *a* (× 37 5)

suggests that the underlying pathology may well have been similar

Hydrocephalus in man has attracted the attention of investigators from ancient times Today most authorities agree that it is often congenital, although the appearance of symptoms may occasionally be delayed until the third or fourth decade The incidence of hydrocephalus due to abnormality of the cerebral aqueduct has been calculated as about 1 in every 9000 births (Woollam and Millen 1953) The authoritative monograph of Dorothy Russell (1949) has clarified the mass of literature on hydrocephalus and has placed its pathology on a sound basis She has classified as the principal maldevelopments of the cerebral aqueduct, stenosis, forking, and septum formation That a deficiency of vitamin A in the mother, and consequently in the newborn, may determine the development of a stenosis of the aqueduct has, however, not hitherto been reported

The clinical picture observed in the present experiments and the histological findings of an obstructive hydrocephalus due to stenosis of the cerebral aqueduct, coupled with the carefully controlled and documented dietary conditions, leave no doubt that there was a causal relationship between the maternal vitamin-A deficiency and the appearance of stenosis of the cerebral aqueduct in the offspring Hydrocephalus and the production of the symptoms of disease of the nervous system followed as a direct consequence of the stenosis

Conclusions and Comment

Although the manner in which the deficiency of vitamin A in the diet of laboratory animals is associated with the production of hydrocephalus by aqueductal stenosis is not yet fully understood, the implications are of great importance The relation of maternal vitamin-A deficiency to hydrocephalus in the offspring opens up a new field of inquiry and merits an extensive clinical investigation

Many important problems concerned with the physiology and pathology of the C S F await solution Surgical interference has been, until now, the only method available for the production of experimental hydrocephalus, and this has been a limiting factor in research into the surgical treatment of the condition The ability to reproduce hydrocephalus in young animals through feeding a diet deficient in vitamin A to the mothers offers a simple and readily available source of hydrocephalic animals for experimental investigations

Many questions remain unanswered and are the subject of further investigation Can hydrocephalus be produced by inadequacy of vitamin-A intake or utilisation after birth ? What is the level of vitamin-A intake necessary to prevent hydrocephalus in the offspring ? Is it possible to arrest hydrocephalus at any stage by supplementing the diet with vitamin A ? Is the aqueductal stenosis a direct result of the deficiency, or is it secondary to some undetermined factor ? At this stage the evidence suggests that the stenosis is the primary condition and the direct result of the deficiency

If the nervous disorders reported in farm animals are equally attributable to stenosis of the cerebral aqueduct, the implications in relation to animal nutrition must be of considerable importance to agricultural economy

Summary

Hydrocephalus occurring in young rabbits as a direct consequence of vitamin A deficiency in the mothers has been investigated.

The underlying cause of this hydrocephalus is stenosis of the cerebral aqueduct

The hydrocephalus has been held to be responsible for the constriction of the optic nerves and for the paralysis found in these animals

These findings are discussed in relation to genetic hydrocephalus and to reports on the effects of vitamin A deficiency on laboratory and farm animals

The discovery of maternal vitamin-A deficiency as a cause of hydrocephalus in the progeny throws open an entirely new field for clinical investigation into the pathology of hydrocephalus, and for experimental observation on the physiology of the cerebrospinal fluid.

We wish to express our gratitude to Prof J D Boyd and Dr J Hammond for their advice and encouragement Thanks are also due to Mr T R L Brooks for the photographs and to Mr R Smith for technical assistance

AUREOMYCIN-RESISTANT STAPHYLOCOCCAL ENTEROCOLITIS

REPORT OF TWO FATAL CASES

D L GARDNER
M.A. Camb , M B Edin , M.R C P E
JUNIOR ASSISTANT PATHOLOGIST, DEPARTMENT OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE

STAPHYLOCOCCAL resistance to the " broad spectrum " antibiotics is attracting increasing attention (Finland and Haight 1953, Needham and Nichols 1953) Hospitals and other closed communities are recognised to be particularly prolific breeding-grounds for resistant organisms (Lepper et al 1953), the source of increasing numbers of infections for which there is no specific therapy (Spink 1953)

Cases have been published in the U S.A. and in France (Janbon et al 1952, Terplan 1953, *Minnesota Medicine* 1953) in which death took place rapidly and unexpectedly in patients under treatment with aureomycin or with oxytetracycline (terramycin) Diarrhœa, electrolyte imbalance, dehydration, and sometimes a choleriform state have developed suddenly while these antibiotics were being given for infections unrelated to the gastro intestinal canal Many of these patients were in the immediate postoperative period, or had been suffering from the effects of malnutrition or chronic alcoholism.

Coagulase positive staphylococci, resistant to the particular antibiotic in use, were isolated in pure culture from the intestinal canal of most of these patients, before or after death The syndrome has therefore become known as acute, or fulminating, staphylococcal gastro enterocolitis In some cases the staphylococci were shown to belong to enterotoxin-producing strains (Janbon et al 1952), but enterotoxin has not been proved responsible for the condition Indeed, it appears probable that similar symptoms can result from the overgrowth of other antibiotic-resistant organisms normally found in the intestine in small numbers

The two fatal cases described below are believed to be examples of this syndrome

Case-records

Case 1 —A Finnish girl, aged 19, complained on Dec 29, 1952 of pain in the feet, left knee, wrists elbows, and shoulders Next day her temperature was 99°F She gave a history of severe sore throat and a raised temperature four weeks previously when she had stayed in bed a week As a child she had had Ludwig's angina at the age of 6 years and scarlatina at the age of 13 The latter kept her in bed for a ith, and at that time it had been suggested that her heart been affected.

xamination revealed limitation of joint movement owing ain, and an inflamed throat

rse of Illness

reatment with soluble penicillin 0·5 mega-unit six hourly begun. Two days later the patient had severe left infra mmary pain and some signs at the base of the left lung umatic fever had been diagnosed, but therapeutic doses spirin had been without effect. By Jan. 9 1953 hæmolytic ptococci had disappeared from the throat and the penicillin discontinued Pain became worse and was accompanied breathlessness, high fever and exhaustion. Treatment h aureomycin, 0·5 g six hourly followed by 250 mg hourly, was superseded three days later because the ent's condition had deteriorated by oxytetracycline g intravenously and 0·5 g six hourly by mouth Peri ditis and pleurisy persisted. On Jan 11 a widespread rbilliform rash developed which lasted three days.

n Jan. 13 the patient began to have more frequent bowel vements, and two days later frank watery diarrhœa ytetracycline, of which 10 g had been given, was dis tinued, and efforts were concentrated on correcting the ere state of fluid imbalance which had developed but she tinued to go downhill, and she died on the evening of . 19

stigations

During the illness blood-cultures had been repeatedly rile, and no organisms of the enteric salmonella or dysen y groups had been isolated from the stools, which contained merous pus cells. On the patient's admission to hospital up-A hæmolytic streptococci had been isolated from her oat Repeated blood-counts showed a moderate to severe ymorph leucocytosis, with a shift to the left and mild mochromic normocytic anæmia. The erythrocyte-sedi ntation rate remained high throughout the illness. The ne was sterile containing only a few granular and hyaline ts and a few pus cells.

t-mortem Findings

Necropsy on Jan 20 showed a well nourished young girl th occasional bruises on the arms. The œsophagus was rmal. The stomach was distended with gas and some ghtly bloodstained fluid. There were occasional small techial hæmorrhages in the mucosa. The small intestine peared normal containing thin faintly turbid, and bile- ined fluid In the distal part of the colon mainly in the ion of the junction of the splenic flexure and the transverse lon, were some submucosal hæmorrhages and areas of hyper nia, with a few superficial erosions. The colon was distended roughout by turbid bile stained fluid Apart from some bmucosal hæmorrhages the rectum appeared normal In e mesentery were some slightly enlarged lymph nodes (up to 3×1·0×0·8 cm.) which had a pinkish mauve hyperæmic rface on section The liver showed some areas of pale que yellow discoloration, anteriorly and inferiorly extend g for a variable distance into the cut surface It was flabby d contained a moderate to considerable amount of fat. A spicuous fibrinous pericarditis gummed together the ricardial surfaces anteriorly but left enough space to ntain 30 ml of bloodstained fluid, in which were some kes of fibrin. The pale flabby myocardium showed no idence of fibrosis or necrosis. The heart valves, apart from moderate hyperæmia of the aortic valve, were normal There re bilateral bloodstained pleural effusions, with a fibrinous urisy corresponding to the posterior parts of both lower bes and both superior diaphragmatic surfaces. The capsules ripped easily from the mottled yellow red renal surfaces d the moderately enlarged spleen showed only congestion.

Histology.—Microscopy showed no significant abnormality the large intestine There was possibly more loss of structure the part of the mucosa next to the lumen than was likely be due to post-mortem autolysis alone but inflammatory anges were at the most very slight There were small as of degeneration, not acute, throughout the heart muscle ociated with atrophied muscle-fibres, brown pigment, and ne and cellular fibrous tissue There was one Aschoff body the myocardium related to the base of the aortic valve.

Bacteriology.—A profuse growth of coagulase positive phylococci was obtained from the respiratory tract the unum, the descending colon, and the rectum. The staphylo cci were resistant to penicillin, aureomycin, and oxytetra cline but sensitive to streptomycin and chloramphenicol nsitivities were determined by a simple filter paper strip diffusion technique using the Oxford staphylococcus as a control organism.)

The *post-mortem diagnosis* was acute gastroenteritis and acute rheumatism with pericarditis and myocarditis.

Case 2.—A retired college servant aged 65 who had had for more than five years severe and progressive osteo-arthritis of the left hip-joint, and had had a Judet arthroplasty done in November 1951 was readmitted for a revision operation because of persistent pain

Examination revealed that movements in the left hip were almost entirely prevented by pain, and that there was great discomfort both on sitting and on lying down. There was obvious pallor the blood pressure was 180/90 mm. Hg and the heart sounds were faint but normal

The Final Illness

On June 17 1953 the old anterolateral Smith Petersen scar was excised and gross thickening and new bone formation found in approaching the left hip joint The old acrylic head was intact but rather mobile. It was removed the rim of the neck re-reamed and a prosthesis of similar size inserted During the operation the patient received a pint of whole blood

On June 18 treatment with prophylactic aureomycin 250 mg four hourly was begun and next day the patient's condition was entirely satisfactory On June 22 he was rather anxious, complained of pain in the operation site, and had a distended abdomen The bowel sounds were normal Paraldehyde 5 ml was given Frequent bowel movements continued all day and the aureomycin was discontinued

On the following night there was sudden collapse without pain the patient remaining fully conscious. The blood pressure was 90/60 mm. Hg No abnormal signs were found in the heart, lungs, or central nervous system. A blood-count showed moderate normochromic normocytic anæmia. Intravenous fluids and intravenous corticotrophin 25 mg were given. A few hours before death it was considered that a staphylococcal gastro-intestinal infection was the probable cause of his collapse A swab from the rectum, taken at this time subsequently produced a profuse pure growth of coagulase positive staphylococci resistant to penicillin, aureomycin and chloramphenicol but sensitive to streptomycin No organisms of the enteric salmonella or dysentery groups were isolated

In spite of treatment the patient died shortly afterwards

Post-mortem Findings

Necropsy on June 25 showed a well nourished elderly man with a recent surgical scar over the anterior aspect of his left hip-joint. When the peritoneal cavity was opened, moderately dilated hyperæmic loops of small and large intestine presented, whose peritoneal surfaces were smooth and shining No free fluid was present in the peritoneal cavity The whole length of the small intestine cæcum and large intestine contained only small amounts of bile-stained watery fluid The mucosal surface of the small intestine showed slight reddish brown congestion. The mucosa of the large intestine was deeply injected, brownish grey and covered with a loosely adherent incomplete film of fibrinous exudate this appearance being maximal in the cæcum, ascending colon, and transverse colon and absent from the descending colon and rectum The mesentery appeared normal The œsophagus stomach, and duodenum were normal The cut surface of the liver was congested and rather flabby but otherwise normal.

There was slight atheroma of the proximal ends of the coronary and cerebral arteries moderate emphysema of both lungs, and firm fibrous adhesions (up to 3 cm. in diameter) at the base of the left lung and at the apex of the right lung

Histology.—Microscopy showed inflammatory changes in the colon considerably less than had been suggested by the naked-eye appearances. In the transverse colon, which was most affected there was considerable leucocytic infiltration in the base of the mucosa with thrombosed small blood vessels and some (possibly autolytic) lack of nuclear staining in the surface half of the mucosa Throughout the submucosa there was an excess of cells most of which were histiocytes or macrophages with some polymorphs

Bacteriology.—A profuse pure growth of coagulase positive staphylococci was obtained post mortem from the respiratory tract, the stomach the ileum, and the colon. The staphylococci were resistant to penicillin and aureomycin. Coliform bacilli were conspicuously absent.

The *post-mortem diagnosis* was acute staphylococcal enterocolitis following a revision arthroplasty

Discussion

In both cases severe ultimately fatal diarrhœa developed unexpectedly during an illness unrelated to the gastro-intestinal canal, in both cases aureomycin or terramycin had been used to treat the primary disease, and in both cases pure profuse growths of coagulase-positive staphylococci, resistant to the particular antibiotic used, were obtained from the intestine before or after death The gram-negative bacilli characteristic of the normal fæcal flora were conspicuously absent

It seems likely that the use of the broad-spectrum antibiotics led to the elimination of all intestinal bacteria except the resistant staphylococci The latter then grew rapidly and within a few days had selectively colonised the entire intestinal canal. The disturbance in intestinal metabolism thus produced may have been sufficient to cause death in both cases Alternatively the production of enterotoxin by the staphylococci may have been responsible

Both cases are probably examples of a syndrome which has become known as acute staphylococcal enterocolitis

Mild gastro-intestinal disturbances accompanying aureomycin or oxytetracycline therapy are common There is almost invariably some change in the bowel flora (*Minnesota Medicine* 1953) These changes are usually sufficient only to cause mild symptomatic discomfort or inconvenience (Janbon et al 1952) In the patient already weakened by previous disease, however, or after severe operation, the disturbance produced by the alteration in intestinal flora may be sufficiently severe to cause death

The prevention of staphylococcal enterocolitis in hospital patients is made more difficult by the high incidence among the staff of nasal carriers of staphylococci resistant to aureomycin and oxytetracycline and by the large numbers of these organisms present in the ward dust In these circumstances the use of the broad-spectrum antibiotics after major operations, or in particularly debilitated patients, is inevitably accompanied by a certain risk

It has been suggested that this risk of severe enterocolitis could be minimised by careful observation of the fæcal flora during the administration of the broad spectrum antibiotics (Sloss cited by *Minnesota Medicine* 1953) The daily examination of a simple gram-stained film of the fæces would be enough to indicate a radical change from predominantly gram-negative bacilli to predominantly gram-positive cocci.

Should the enterocolitis develop suddenly, and be recognised as a complication of the antibiotic therapy, the only specific treatment for the condition would be to encourage the return of the normal bowel flora This can be done by stopping the antibiotic in use and by substituting a drug to which the staphylococci remain sensitive. Sloss suggested that erythromycin could be used Most staphylococci appear still to be sensitive to this antibiotic, which is known to have little action against the gram negative bacilli (Herrell et al 1953)

Summary

The broad spectrum antibiotics often cause radical changes in the normal flora of the intestinal canal When these changes take place in patients who have recently undergone a serious operation or have some debilitating disease the diarrhœa which follows may be very severe

Two cases are described in which death resulted from the intestinal proliferation of coagulase-positive staphylococci following the administration of antibiotics to which these staphylococci were resistant It is uncertain whether staphylococcal enterotoxin was responsible

This form of staphylococcal enterocolitis may be avoided by daily observation of the predominant fæcal flora Should severe diarrhœa develop, it may be possible to encourage a return of the normal bowel flora by the use of another antibiotic, such as erythromycin, to which the staphylococci are known to be sensitive an does not suppress the gram-negative bacilli.

I wish to thank Dr A M Barrett, university mo anatomist, and Dr M H Gleeson-White, university bac logist, for their advice, and Mr T J Fairbank, or surgeon to Addenbrooke's Hospital, for permission to p his case records.

AMINO-ACID COMPOSITION OF EIG DERMATOPHYTE FUNGI

P J Hare
M D Johns Hopkins, M.R.C.P
CONSULTANT DERMATOLOGIST, UNIVERSITY COLLEGE HOS
LONDON

THE amino-acid composition of eight dermatop fungi has been determined qualitatively, by chromatography, using acid hydrolysates of the grown in a simple fluid medium with ammonium sul as the source of nitrogen

METHOD

Microsporum audouini Gruby, *M canis* Bodin, *gypseum* (Bodin) Brumpt, *Trichophyton mentagrop* (Robin) Blanchard var. *gypseum*, *T. discoides* Sabou *T violaceum* Bodin, *T rubrum* (Castellani) Sabou and *Epidermophyton floccosum* (Harz) Langeron Milochevitch were cultured on beerwort agar transplants of aerial mycelium were made into 5 quantities of a liquid medium in conical flasks of 15 capacity The medium was composed of glucose ammonium sulphate 4 g, KH_2PO_4 5 g, K_2HPO_4 magnesium sulphate 0 25 g, ferrous sulphate 1 manganese chloride 1 mg, zinc sulphate 1 mg distilled water 1000 ml, sterilised in an autoclave fungi were allowed to grow at room-temperature occasional agitation by hand. They grew as ma the surface of the medium Only *M. canis* sho distinctive microscopical features under these condi but all the fungi yielded identifiable subcultures beerwort agar

At intervals up to three months the cultures harvested, filtered free from medium, washed distilled water, and dried in an oven at 60°F, with average yield of 300 mg of dry mycelium. The were then hydrolysed with 6*N* HCl for twenty-four ho The hydrolysates were thrice reduced to dryness washed with distilled water The yield was taken in a small volume of distilled water, and samples submitted to two-dimensional partition chromatogra on filter paper, using phenol and 'Collidine' as solv (Dent 1948) *Duplicates* were prepared after treatm of samples of the hydrolysates with hydrogen pero and ammonium molybdate The papers were spra with 'Ninhydrin' to detect the amino acid spots papers were also treated with Pauly's diazo reagent removal of the solvents with acetone

RESULTS

The qualitative results were similar in each Spots corresponding to the expected sites of the follo were seen aspartic acid, glutamic acid, glycine, nine alanine histidine, lysine, arginine, proline, leucine(s) tyrosine cystine (as cysteic acid after tion) [illegible] and methionine (as its sulphone ation) Glucosamine presumably derived from us polysaccharide, was also present No hydroxy ine was detected Tryptophane does not survive hydrolysis baryta and tryptic digests provided tisfactory material for its detection

o great quantitative differences were observed in the position of the eight fungi, judged by the size and nsity of the colours of the spots. The amino acids greatest concentration were the leucines, valine, ine glutamic acid, and aspartic acid These results e at least qualitatively similar to those for various pathogenic fungi (Work and Dewey 1953) including *rospora crassa* *Aspergillus glaucus*, and *Cephalo* *ium acremonium*

DISCUSSION

he fungi producing superficial mycoses grow in the ny layer of the epidermis, the nail plate or the hair t. These structures are composed largely of keratin y also contain non protein substances derived from r parent tissues. Bolliger (1951) for example has onstrated the presence of 3 5% of water soluble stances in clipped rabbit fur Watery extracts of nan hair support the growth of ringworm fungi lsher 1940) but there is little doubt that keratin is r main source of nourishment in parasitic life They e been cultured on pure keratin (MacFadyen 1896) hough no keratolytic enzymes have been found in se fungi (Tate 1929) keratin is undoubtedly broken m. In the case of *M gypseum* the degradation of wool been followed in detail (Stahl et al 1949a and b, 1950) he ability of the dermatophyte fungi to utilise ino-acids has been investigated by various workers g., Robbins (1950) Archibald and Reiss (1950), and mson and Grimm (1951) In such studies the compara e value of various amino acids as sources of nitrogen been examined by adding them singly and in com ation to otherwise complete synthetic media. In eral it has been shown that almost any amino acid l permit the growth of these fungi The sulphur taining amino-acids, so abundant in keratin are nparatively poor sources of nitrogen for the dermato ytes. They do not grow if hydroxyproline is given the sole source of nitrogen. Rothman (1951) has gested that these fungi are obligate parasites of atin because hydroxyproline is absent from the latter

The present study shows that the strains of the eight gi investigated can utilise ammonium sulphate as ir source of nitrogen and that they are autotrophic vitamins. It is not suggested that optimal growth s obtained. The amino acid composition of these gi appears to be similar to that of non pathogenic gi and does not explain the parasitic growth of gworm fungi in keratin. Hydroxyproline was not tected and presumably does not enter into the nitrogen tabolism of these fungi.

SUMMARY

The amino acid composition of eight dermatophyte ngi is qualitatively similar to that of non pathogenic ngi.

No hydroxyproline was detected

I wish to thank Prof. Wilson Smith Dr C. E Work and D Dewey for facilities, guidance and technical aid

LOCALISED PRETIBIAL MYXŒDEMA
TREATED WITH CORTISONE

R S M D INCH
M B Edin M R C P E
REGISTRAR

C F ROLLAND
B A Camb M.B Edin, M R C P E
SENIOR REGISTRAR AND LECTURER IN THERAPEUTICS

From the Department of Therapeutics Edinburgh University and the Clinical Laboratory Royal Infirmary Edinburgh

PRETIBIAL myxœdema is usually regarded as a rare complication of, or sequel to hyperthyroidism, but Trotter and Eden (1942) suggested that it may occur in as many as 3% of hyperthyroid cases The first English description was given by Watson Williams in 1895 but since then it seems to have been of greater interest to the dermatologist than to the endocrinologist

Pretibial myxœdema is said to be always bilateral though not necessarily symmetrical and the deposits may not appear simultaneously on both legs and may not develop at the same speed. The histological and biochemical features have been well described by Watson and Pearce (1947) Other workers agree that the connective tissue of the cutis is infiltrated with mucopolysaccharides. The appearance of the skin, with its irregular surface and sparse coarse hair is sufficiently recognised and requires no further description

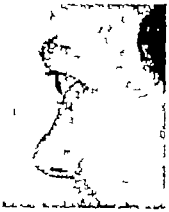

Fig 1 (case 1)—Exophthalmos.

The ætiology of the condition is unknown but is the subject of two hypotheses (1) that the development of the localised myxœdema is the direct result of an unexplained insensitivity of the pretibial tissues to the action of the thyroid hormone and (2) that the lesions, like the exophthalmos with which they are almost always associated are caused in some way by overproduction of the thyrotrophic hormone of the anterior pituitary (Vilanova and Canadell 1949) At present there is little evidence to support either hypothesis.

Various forms of treatment, such as local excision oral and local administration of thyroxine radiant heat, massage and local injections of hyaluronidase have all proved disappointing and Trotter and Eden (1942) concluded that the lesions were not affected by any form of treatment in use at that time

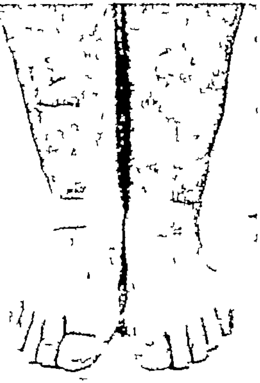

Fig 2 (case 1)—Pretibial myxœdema and deposit on dorsum of right hallux.

We report here three cases which showed some interesting features and describe our experience of the use of cortisone acetate in this condition

Case-reports

Case 1 —A woman developed hyperthyroidism at the age of 36 For the first eight months she was treated with methyl thiouracil, and exophthalmos appeared. As control was unsatisfactory, partial thyroidectomy was performed she subsequently became hypothyroid, and her exophthalmos increased. Coincidently pretibial myxœdema appeared on both legs and her fingers became clubbed About nine months after the operation thyroid treatment relieved the hypothyroidism but had no effect on the pretibial myxœdema Ophthalmoplegia began to complicate the exophthalmos and sixteen months after thyroidectomy her pituitary was irradiated without effect Some three months later she was seen by us for the first time Though her myxœdema was controlled, she had exophthalmos (Hertel exophthalmometer right eye 26 mm., left eye 26 mm.) (fig 1), mild ophthalmoplegia, gross bilateral pretibial myxœdema (fig 2), and marked clubbing of the fingers (fig 3)

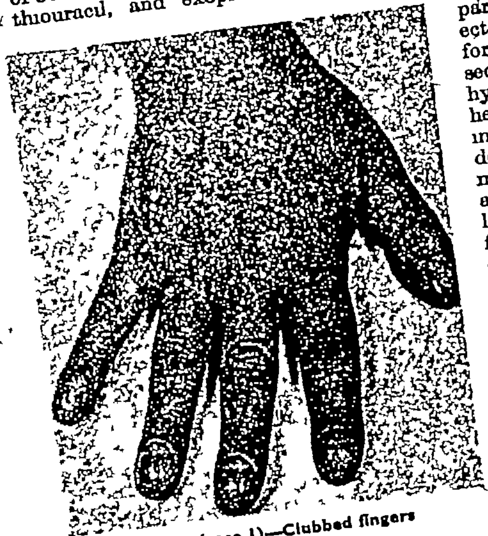

Fig 3 (case 1)—Clubbed fingers

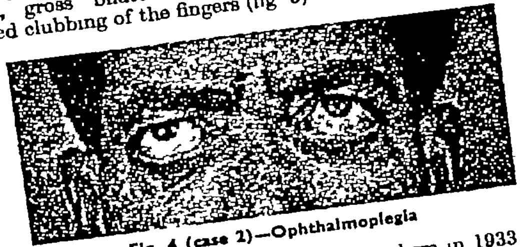

Fig 4 (case 2)—Ophthalmoplegia

Case 2 —A man developed hyperthyroidism in 1933 at the age of 20 and was treated by X irradiation of the thyroid gland He became euthyroid but developed exophthalmos and mild ophthalmoplegia. He remained in full time employment as a miner, but when aged 36 sustained a trivial injury to his left leg and thereafter developed pretibial myxœdema at the site of injury This was soon followed by slight pretibial myxœdema of the other leg A year later the left leg was incised without benefit to the pretibial myxœdema, and a large keloid scar developed at the site of the incision He was first seen by us when he was 39, and although he was euthyroid he had considerable exophthalmos (Hertel exophthalmometer right eye 25 mm , left eye 26 mm.), some ophthalmoplegia (fig 4) and chemosis conjunctivæ The pretibial myxœdema (fig 5) with its keloid scar formed a large mass on the left leg, and there was a smaller area on the right leg, with a pad on the dorsum of the left hallux (fig 6) He also had gross finger clubbing (fig. 7) but did not know when this had started.

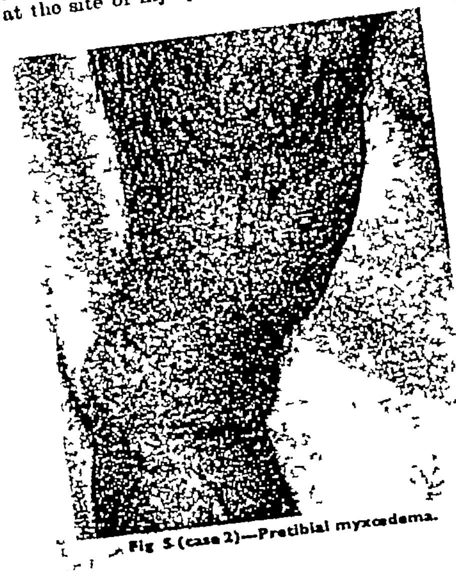

Fig 5 (case 2)—Pretibial myxœdema.

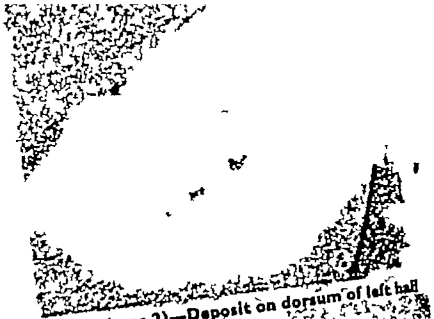

Fig 6 (case 2)—Deposit on dorsum of left hal

Case 3 —A woman had developed myxœdema at the age of 44 and had been treated with thyroid extract She rema well until bilateral exophthalmos appeared at the age of and this was soon complicated by circumorbital œdema ophthalmoplegia, and extensive bilateral pretibial myxœdema When first seen by one of us at the age of 50 she was inade quately controlled with thyroid , and, when the dose of was increased, her ophthalmoplegia disappeared, but exoph thalmos remained, and her pretibial myxœdema was unaffected There was no clubbing of the fingers

This case was exceptional because there was no eviden that the patient had ever had hyperthyroidism.

Treatment

Case 1 was admitted for a trial of the effect of la doses of cortisone in the treatment of exophthalmic ophthalmoplegia (Chandler and Hartfall 1952) She wa given cortisone acetate suspension (Merck) by intramuscular injection After she had had 0 8 g in six days, the plaques of pretibial myxœdema had become softer, especially at their edges, but the exophthalmos was unchanged The systemic administration of cortisone was then supplemented by infiltrating the suspension into an area of pretibial myxœdema An isolated plaque abo 3 cm in diameter was chosen, and 25 mg of cor sone acetate (1 ml of the suspension) was infiltrat with a long fine needle The injection was alm painless, and twenty-four hours later the infiltrated a showed a considerable change compared with untreated part of the plaque The area had shrunk, skin over it had wrinkled and become slightly cyano and the firm thick tissue of the pretibial myxœdema disappeared Two further infiltrations of the same led to the almost complete disappearance of the pla Thereafter the intramuscular injections were di tinued because no improvement was evident in exophthalmos after 1 5 g of cortisone had been adi tered in seventeen days It was, however, thought while to continue the local infiltration of cortisone in

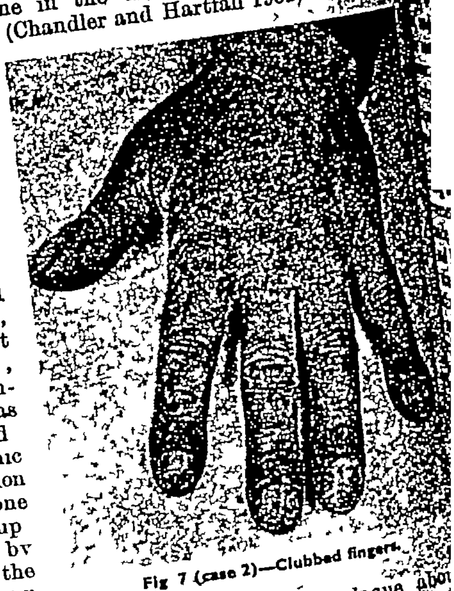

Fig 7 (case 2)—Clubbed fingers.

etibial deposits, and 0·625 g was given in this way in irteen weeks. Although some improvement followed ch infiltration this was less striking than that achieved en cortisone was given systemically in addition to the al infiltration. Hyaluronidase 500 units in 1 ml of ysiological saline solution injected into the pretibial posit so changed its character that within a few minutes became an area of pitting œdema On three subsequent casions a similar dose of hyaluronidase was mixed with ml. of cortisone suspension and infiltrated into the etibial plaque in the hope that the cortisone would ert a more widespread action, but this expectation was t fulfilled The pretibial myxœdema gradually reverted its previous state after the infiltration of any particular ea had been discontinued for some time In view of this e treatment was abandoned

In case 2 intramuscular cortisone was also given for e exophthalmic ophthalmoplegia and 1·0 g was jected in seventeen days without improving the ophthalmos As in case 1 the addition of local filtrations of cortisone given during the period of stemic injections, led to a striking improvement in the etibial myxœdema. When the intramuscular injections ere stopped the local treatment was less successful and versal to the original state took place when the local eatment was abandoned This patient received 0·212 g cortisone by local infiltration in four weeks. Hyaluronidase again failed to increase the effects of the cortisone filtration, and the keloid scar was completely unaffected y the treatment.

Case 3 was not given intramuscular cortisone. In this tient the effects of cortisone infiltration in one leg were mpared with those of hyaluronidase in the other ortisone 0·7 g was infiltrated into the left leg in eleven eeks, and hyaluronidase 9000 units into the right leg the same time In the left leg there was a slight provement after each injection about the same as at induced in the other two patients by the purely local jection of cortisone. In the right leg pitting œdema llowed the injection of hyaluronidase and on two casions the bulk of the plaques was decreased by spirating some of the fluid from the pitting areas The provement, however was transient, and if no aspiration as made the plaque ceased to pit within two or three ys and became indistinguishable from its original state

On the supposition that the pretibial myxœdema and ophthalmos might be different manifestations of the me process, 1 ml of the suspension containing 25 mg f cortisone was injected by Dr G I Scott into the tro-ocular tissues of cases 1 and 2 on the last day of their eatment with systemic cortisone. The only result was a mporary increase in the chemosis, and there was no provement in the proptosis as measured by the ophthalmometer

Conclusions

Intramuscular therapy with large doses of cortisone roduced slight but definite improvement in the pretibial yxœdema of two patients and this improvement was ore striking with the addition of local infiltration of rtisone Local infiltration without any systemic erapy was much less effective in all three cases. We are nable to explain the mechanism by which this combined eatment with cortisone proved beneficial

Although our limited observations suggested that it ight be possible to eradicate pretibial myxœdema by long-continued treatment with systemic and local jections of cortisone, such an attempt was thought njustifiable (1) because of the large amount of cortisone equired, (2) because of the danger of the side-effects of rtisone used in such high dosage and for so long and (3) because of the tendency of the condition to relapse hen treatment was stopped.

The use of hyaluronidase in this condition has already een reported by Rosman (1950) and our studies confirm his opinion that this form of treatment is of no permanent value, further the effect of cortisone is not enhanced by mixing it with hyaluronidase

Although the association of exophthalmos with pretibial myxœdema has often been described, we have not been able to find any reference to gross finger clubbing in such cases Since our interest in this association was aroused by its occurrence in our first two patients we have heard of two other patients in whom the same triad of signs was present The reason for this association is unknown but Coope (1948) mentions that clubbing of the fingers develops occasionally in myxœdema after thyroidectomy

Summary

Three cases of pretibial myxœdema are described In two of them exophthalmic ophthalmoplegia was associated with gross clubbing of the fingers This triad does not seem to have been described before

The effects of treatment with cortisone are described Combined systemic and local injections were followed by definite but temporary improvement in the pretibial myxœdema Local treatment alone was less effective Nevertheless reasons are given why long-continued combined treatment is unjustifiable

Retro-ocular injections of cortisone in two cases failed to improve the exophthalmic ophthalmoplegia

Our thanks are due to Prof D M Dunlop for permission to publish these observations on patients under his care and for his help and advice in the preparation of this paper to Dr G I Scott for undertaking the retro-ocular injections of cortisone to Dr P Hannay for asking us to treat case 2; to Sister E Mutch for her assistance in the treatment of all three cases and to the photomicrography unit of the University of Edinburgh for the photographs

CORTICOTROPHIN TREATMENT IN POLYNEURITIS WITH PERIARTERITIS NODOSA

L A. LIVERSEDGE
M.B., B Sc Manc. M D Duke M.R.C P
LECTURER IN NEUROLOGY IN THE UNIVERSITY OF MANCHESTER

H M LEATHER
M B Birm M.R C.P
MEDICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY

MANY theories have been put forward to explain the acute polyneuritis originally called the Guillain Barré syndrome (Guillain et al. 1916) and now passing under various names such as infective polyneuritis infective neuronitis, and polyradiculitis The view has gained favour recently that it is allergic in origin and a number of workers have therefore treated it with cortisone or corticotrophin (A.C.T.H.) Favourable results have been reported (Newey and Lubin 1953 Blood et al. 1953)

The association of peripheral neuropathy with periarteritis nodosa is well recognised (Kernohan and Woltman 1938 Miller et al. 1949 Summers 1950) the neural disturbance varying from a localised asymmetrical mononeuritis to a diffuse symmetrical polyneuritis Periarteritis is said to respond at times to treatment with corticotrophin and may reasonably be regarded as a manifestation of hypersensitivity Hence it is possible that the associated polyneuritis is also allergic in origin

There are as yet few reports of the use of corticotrophin in the treatment of the Guillain Barré type of polyneuritis occurring with periarteritis The following case is therefore of interest in its therapeutic and ætiological implications.

Case-record

A woman, aged 58, had rheumatic fever in 1910, at the age of 16, with possible involvement of the heart. Subsequently she remained well until 1940, when joint pains and swellings affected mainly the larger joints. These pains recurred intermittently during succeeding years but were never disabling. In July, 1952, however, she developed rather more severe pains and swellings in the knees and hands. She was seen then at the Manchester Royal Infirmary, where examination revealed slight limitation of movements of the hips and knees, swelling of the interphalangeal joints of the hand, and a soft early diastolic murmur down the left border of the sternum. A full blood count was normal, but the erythrocyte sedimentation rate (E.S.R.) was 44 mm. (Wintrobe) in the first hour. Her symptoms were relieved after three weeks' treatment with analgesics and physiotherapy. In February, 1953, an attack of postprandial dyspepsia, to which she had been liable for thirteen years, led to a barium meal examination, which revealed a deformed duodenal cap but no actual ulcer. At this time a blood count showed red cells 4,310,000 per c.mm. and Hb 64%. Medical treatment relieved the dyspepsia, and oral iron therapy increased the Hb to 82% in six weeks. The patient's general health seemed to her to deteriorate, however, and she began to lose weight. On May 15 she developed a severe aching pain across the middle of her back, with an associated numbness of both feet. This numbness spread up the calves within a few hours, and the leg muscles became painful. Next day she felt generally ill, the pain was worse, and the numbness had reached her knees. She was admitted on May 17 to the Manchester Royal Infirmary under the care of Dr. N. Kletts.

On examination the patient appeared ill and in great pain. Her temperature was 98°F and blood pressure 200/100 mm. Hg. A diastolic murmur was heard down the left sternal border. Rheumatoid changes in the hands, effusions into both knees, slight œdema of the ankles, and slight epigastric tenderness were present. The liver was palpable. There were no abnormal motor signs in the central nervous system. The tendon reflexes were absent; plantar reflexes could not be elicited. There was symmetrical loss of all forms of sensation below the knees.

Investigations.—A catheter specimen of urine showed much albumin, some epithelial cells and red cells, but no porphyrins. A blood count showed red cells 4,400,000 per c.mm., Hb 80%, white cells 9200 per c.mm. (polymorphs 70·5%, lymphocytes 25%, monocytes 4%, eosinophils 0·5%). The E.S.R. was 54 mm. in the first hour. Radiographs of the dorsal and lumbar spine were normal. Lumbar puncture produced cerebrospinal fluid (C.S.F.) under a pressure of 120 mm. H_2O, dynamics normal and containing 1 lymphocyte per c.mm., protein 100 mg. per 100 ml., and enough globulin to render it opalescent. The Lange curve was normal. The Wassermann reaction was negative in blood and C.S.F. The blood urea level was 50 mg., the serum albumin 3·3 g., and the serum globulin 3·6 g., per 100 ml., thymol turbidity 5·1 units, and alkaline phosphatase 13·5 King Armstrong units. A pyrocate tolerance test was normal.

Progress.—After two days the back pain eased. The patient's temperature reached 99°F occasionally. Six days after admission she woke to find that she could not move her legs, and that the fingers of both hands were numb. Re-examination revealed complete flaccid paralysis of both legs, in addition to the absent reflexes and the sensory loss previously noted. Calf tenderness was now pronounced. The right posterior tibial artery and the dorsal arteries of the right foot could not be palpated, and the right foot was much cooler than the left. Muscle biopsy (from the left pectoral) revealed no abnormality.

Diagnosis.—Despite the negative biopsy result, the clinical evidence in favour of a diagnosis of periarteritis nodosa seemed overwhelming. The multiple systemic involvement included hypertension, joint changes of rheumatoid type, œdema, albuminuria, anæmia, raised blood urea level, raised E.S.R., evidence of arterial blockage, an enlarged liver with alteration of the serum protein levels, and peripheral neuritis.

Treatment.—In view of the favourable reports of treatment cited above there was a double indication for corticotrophin therapy. On May 20, therefore, five days after the onset of the severe paralysis, treatment with intramuscular corticotrophin gel 20 mg. b.d. was begun. Within twenty-four hours the calf tenderness had disappeared, the patient could move her toes and ankles, and the sensory impairment had receded to the ankles. Absolute constipation, which had resisted treatment for fourteen days, was relieved spontaneously in forty-eight hours. By the sixth day of treatment the patient walked a few steps, and on the tenth day sensory impairment wa limited to the tips of the fingers and toes. At this time she could walk unaided for fifty yards. The effusions disappeared, but the occlusion of the arteries of the right foot persisted. Treatment was discontinued after thirty days, and on July 17 sh was discharged in excellent health.

Re-examination on Nov. 11 showed that her excellent condition was maintained, and by this time all the tendon jerks could be elicited though they were sluggish.

During the course of corticotrophin treatment the patient showed a good eosinophilic response. Certain interesting changes took place in addition to the other accessory clinical findings.

	Days after beginning treatment			
	0	10	21	3
E.S.R.	62	10	13	
C.S.F. protein (mg. per 100 ml.)	100			
Serum albumin (g. per 100 ml.)	3·3	3·1	3·4	4
Serum-globulin (g. per 100 ml.)	3·6	3·5	2·5	2
White-cells per c.mm.	10,800	10,600	9800	89
Polymorphs %	71	84	74	7

The reversion of the serum protein levels to the norma albumin/globulin ratio, the reduction of the E.S.R., an the decrease in the amount of C.S.F. protein follow th clinical improvement very closely indeed.

Discussion

The course of an untreated polyneuritis is rathe variable, which fact makes assessment of treatmen difficult. In the present case, however, the immediat relief of symptoms, which in the previous two weeks ha been developing steadily, coupled with the paralle alteration in certain of the accessory findings, suggests direct benefit attributable to the corticotrophin. Bloo et al. (1953) reported amelioration of severe symptom within four days of beginning treatment in their case, an Newey and Lubin (1953) report demonstrable improvement within thirty minutes of the conclusion of an eight hour intravenous infusion of corticotrophin 25 mg. I is too early to judge the final effect of this form of therap because a relapse may yet occur.

The association of the polyneuritis with a diffus collagen disease—the diagnosis of periarteritis nodosa appears inescapable—raises the question of the pathological process underlying the nerve changes. Lovshi and Kernohan (1949), Miller et al. (1949), Macken et al (1951), and Sahlgren and Hofman-Bang (1950) al describe pathological changes in the vasa nervorum and attribute the neural lesion to ischæmia of the nerve. The symmetrical peripheral distribution of the signs and symptoms is usually attributed to the fact that the longest neurones (running to the periphery) are the most susceptible to the ischæmia. Macken et al. state that th occluded vessels can be recanalised. The explanation o the rapid recovery in the present case may therefore li in the rapid resolution of the subintimal proliferation i the vasa nervorum and immediate relief of the ischæmia. On the other hand, if one regards this symmetrica peripheral neuritis as another manifestation of hypersensitivity, the response to corticotrophin might be attributed to an immediate reversal of biochemical and osmotic changes in the neurones. However, as Mille et al. (1949) point out, perhaps in infective polyneuriti the primary lesion is vascular and not neuronal.

Summary

A case of severe symmetrical polyneuritis with *dissociation albumino-cytologique* of the Guillain Barré type occurring during the course of periarteritis i described. Both conditions responded rapidly to treatment with corticotrophin.

It is suggested that the process underlying this and possibly other forms of polyneuritis is that of tissue hypersensitivity leading either to ischæmia or to more

plex biochemical changes in the neurones These
ges are susceptible of immediate reversal as shown
he rapid response to corticotrophin in the present

are indebted to Dr N Klotts for permission to record
nse and for helpful criticism in preparation of the paper

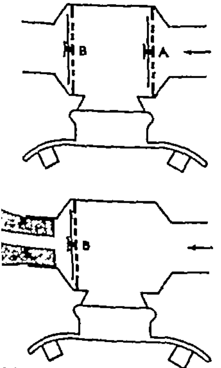
SENIOR ANÆSTHETIST

R W Gilliatt
B.M. Oxfd M R C P
HOUSE PHYSICIAN

E NATIONAL HOSPITAL FOR NERVOUS DISEASES
QUEEN SQUARE LONDON

E simple mechanical pneumoflator designed by one s (Beaver 1953) was introduced to provide positive sure respiration during anæsthesia and in cases of re respiratory paralysis due to poliomyelitis For purpose the pneumoflator has been used successfully conjunction with an endotracheal tube or with an sthetic mask of the self sealing type (Goorney 1953) n acute poliomyelitis with bulbar or spinal respiratory ure expert supervision of positive pressure respiration bviously necessary but in chronic or slowly recovering al paralysis the problem is rather different Such ients are best nursed in the conventional box respirator, and the rôle of positive pressure inflation is then to permit severely paralysed patients to be withdrawn from the respirator long enough for nursing attention and physiotherapy to be given efficiently An ingenious positive pressure hood for use with the Both respirator has recently been designed for this purpose (Christie and Esplen 1953)

For these long term respirator cases positive pressure inflation through an anæsthetic mask has the disadvantage that it requires the presence of a doctor or of a specially trained nurse to ensure a good fit of the mask the face and to maintain an adequate ventilating ssure without obstruction of expiration and it is not ways easy to provide adequate supervision for patients quiring positive pressure four or five times a day For is reason a simple non-adjustable mouth piece has been improvised for use with the pneumoflator which makes it possible for assisted respiration to be given safely by the nurses.



1—Standard Siebe Gorman mouth ece above, modified mouthpiece low. For explanation of lettering e text.

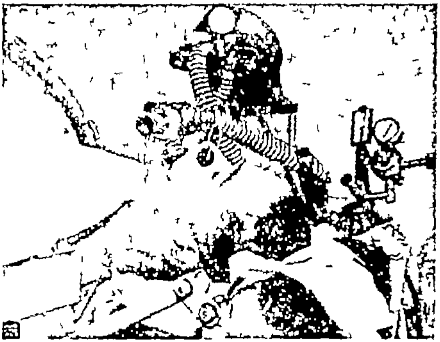


Fig 2—Mouth-piece in use.

The mouth piece (fig 1) is adapted from the standard Siebe Gorman valved mouth piece (catalogue code-word 'Exnick) which is gripped in the patient s teeth, the nose being clipped (fig 2) The inspiratory valve (A) of the mouth piece is removed so that no mechanical barrier exists between the pneumoflator and the mouth but the expiratory valve (B) is retained, and to provide suitable positive pressures during the compression phase a rubber cork (C) bored to leave an air outlet of $^1/_4$ or $^3/_{16}$ inch in diameter is fitted into the outlet Without further adjustment the pneumoflator will then deliver through the mouth piece air or an air/oxygen mixture at a pressure of 10–20 cm of water during compression. No rebreathing takes place and with an outlet bore of the size mentioned there is no appreciable resistance to expiration.

By slight variation in the bore of the outlet hole in the rubber cork, or by the insertion of a short length of glass tubing to reduce its internal diameter the positive pressure produced can be varied between 10 and 20 cm of water without appreciable resistance to expiration and, with a suitable series of corks pressure can be slightly reduced at weekly or monthly intervals according to the degree of recovery of spontaneous respiration.

With this extremely cheap and simple adaptation of a standard piece of equipment positive pressure respiration by pneumoflator becomes a safe routine procedure making it possible to maintain a severely paralysed patient out of a box respirator for long periods without expert supervision At first a patient may be quickly tired by the effort of gripping the mouth piece but within a few days this no longer happens and the patient develops great confidence in the apparatus knowing that if the bite on the mouth piece is maintained no external leak or maladjustment can arise Because the patient is required to grip the mouth piece firmly with his lips and teeth it is only suitable for those with chronic spinal paralysis without bulbar involvement

In one patient with severe spinal paralysis (vital capacity less than 250 c.cm) the pneumoflator and mouth piece have been used four or five times each day for many weeks with a daily total of two or three hours of positive pressure breathing This has allowed a standard of nursing and physiotherapy far in advance of that which could be contemplated if the patient s spontaneous respiration were relied on when out of the box respirator

We particularly wish to thank the many nurses whose coöperation has made routine positive-pressure breathing possible

Reviews of Books

Approach to General Practice

R J F H PINSENT, M A, M D Camb Edinburgh E & S Livingstone 1953 Pp 166 12s

THIS excellent book answers well to its title In it the intending or actual recruit to general practice will find a clear picture of his future professional life Dr Pinsent is never vague or off the ground He writes as a thoughtful, experienced family doctor, conscious of the duties and opportunities of general practice but not blind to the frustrations and annoyances Established practitioners who read the book will gain an insight into the methods and outlook of a colleague, and specialists a view into what is, unhappily, becoming for many of them *terra incognita*

The chapters on The Surgery, The Doctor's Office, and Treatment in General Practice are full of useful facts and practical suggestions Others, such as those on The Mind of the Doctor, The Education of the Patient, and The Future of General Practice, are more reflective Clear-headedness and reason in all dealings with patients is one of Dr Pinsent's main themes The doctor must not deceive himself by pandering to some patients' woolly conceptions, he must labour to get *their* heads clear too "no placebo under 40 and no tonic at all"

The author is on the whole optimistic about the future of general practice, which he believes will be linked inseparably with that of its College He sees a future for the "general-nursing practitioner" who might "be admitted into junior partnership with the doctor himself"

Surgery of Repair as Applied to Hand Injuries

B K RANK, M S Melb, F R C S, F R A C S, plastic surgeon, Royal Melbourne Hospital, A R WAKEFIELD, M S Melb, F R C S, F R A C S, plastic surgeon, Children's Hospital, Melbourne Edinburgh E & S Livingstone 1953 Pp 256 40s

RECOGNITION of the importance of hand injuries is slowly spreading, and some hospitals now have special departments for dealing with these cases This book will appeal not only to surgeons practising in this special field, but to all general surgeons whose emergency work is sprinkled with hand injuries

The first part describes the social significance of the problem, arrangements for the reception of cases, the special anatomy of the hand, and the clinical examination required The second part deals with primary treatment, which is the most important of all, the third part with intermediate treatment, and the fourth part with secondary treatment The fifth and last part describes the special features of the burnt hand, hand injuries in children, and hand prostheses The whole book is illustrated with good photographs of actual cases

Only a knowledge of plastic surgery can save portions of the hand and fingers which would otherwise be lost, and the section dealing with reconstructive methods applicable to the more severely injured hand is excellent The section on tendon repairs, which are notoriously difficult, is extremely good Mr Rank and Mr Wakefield clearly explain the methods of repair they have found most satisfactory, and their illustrations show the good results that can be obtained

Clinical Endocrinology

LEWIS M HURXTHAL, M D, F A C P, head, department of internal medicine, Lahey Clinic, Boston, NATALIJA MUSULIN, M D, staff of Cooper Hospital, Camden, N J Philadelphia and London J B Lippincott 1953 2 volumes Pp 1600 £9 9s

THE standard work on clinical endocrinology has not yet appeared, nor can it be written until the present phase of rapid advance in this field gives way to a period of consolidation and consideration Meanwhile we are offered on the one hand rather lightweight introductions to what is generally regarded as a difficult subject, and, on the other, unreadable but indispensable works of reference This book falls into the latter category, but the authors have gone one step further than their predecessors they intend this to be a true work of reference and have virtually excluded continuous prose All th material (and it is abundant) is presented in outline forn as a series of lists painstakingly and intelligentl classified, backed by copious references both to early an to recent work, and profusely illustrated This is synopsis rather than a textbook, useless and possibl dangerous to anyone not working in the field, bu invaluable as a labour-saving device to everyone wh practises endocrinology, and particularly to tho engaged in clinical research Here and there tentativ results and rather speculative hypotheses seem to b given equal weight with well-established facts, th references listed must therefore be used with som discrimination

Transactions of the 4th Meeting of the Internation Society of Geographical Pathology

Editors H. H. BETZ and FRED C ROULET Bas and New York S Karger 1953 Pp 396 Sw 46.8

THE *Schweizerische Zeitschrift für allgemeine Patholog und Bakteriologie* have devoted the whole of part 3 o their current volume to a detailed report of the transactions of the 4th meeting of the International Societ of Geographical Pathology held at Liège on July 15-1 1952

The conference was concerned almost exclusively wi infective hepatitis, and included, in addition to individu communications from distinguished investigators, a series o special reports based on the results of a world wide questio ary Among these are a brief summary of the epidemiolog of virus hepatitis, by MacCallum, and a report by Sherlock o the biochemical aspects of acute hepatitis, based on repli received from 22 different countries as far apart as Chile an Japan, Finland, and South Africa. The report contains 4 papers of consistently high standard, and brings together no only the clinical and experimental findings of recent year but much information on related hepatic diseases such a epidemic icterus in French Equatorial Africa, leptospiros and amoebic and parasitic hepatitis The value of th geographical approach to the study of the disease is emphasise by May's outline of the exciting medical programme of th American Geographical Society

Textbook of Physiology and Biochemistry (2nd ed Edinburgh E & S Livingstone 1953 Pp 1002 50s)— Physiology enters more and more into modern medica thought, and a textbook on the subject, with two profes sors of physiology (Prof George H Bell and Prof. J Norman Davidson) and a distinguished clinician (Prof Harol Scarborough) as its authors, raises high hopes Unfortunatel they are not quite fulfilled in this book, since many section on fascinating subjects have somehow been allowed to mak dull reading Normal phenomena acquire meaning b contrast with the pathological hence the chapters o vitamins and endocrinology are much more alive than mos of the other sections The circus movement theory of auricula fibrillation has been superseded by an account of Prinzmetal' recent work, but unfortunately a good deal of the rest of th book is not as up to date as this. The introductory chapter on biochemistry are more chemical than physiological, an it is difficult to see how the medical student can achieve reasonable synthesis from this disjointed mode of presentatio Needlessly complex accounts are given of matters which coul be expressed as very simple principles A new orientation o teaching in the direction of human physiology is a crying nee in the strenuous curriculum of the medical student toda and this book goes a little way—but only a little way—to mee that need More courage is required to break with the dust past and provide the student with a stimulating and viv account of matters which should become a permanent par of his intellectual equipment But the book is orthodox, an the student who bases his studies upon it will no doubt pa the appropriate examinations.

Supplement to the S.F.A Catalogue of Medical Film (London Harvey & Blythe 1953 Pp 55 6s)—Th *S F A Catalogue of Medical Films* appeared in 1952, bu already some 260 candidates have applied for inclusion Th are well accommodated in this supplement, with the help o which the complete catalogue now gives information on ove 1200 medical films. The supplement should be used with th main catalogue, which contains guidance on the way to us it and a key to abbreviations.

THE LANCET

LONDON SATURDAY DEC 12 1953

Sources of Congenital Heart-disease

DEVELOPMENTS in the surgical treatment of ongenital heart-disease have led to closer study of s *prevalence and causation The true prevalence* unknown, but the observation by McMAHON, lcKEOWN *and* RECORD[1] *that, among nearly two* undred thousand children born in Birmingham etween 1940 and 1949 3 2 per 1000 were affected ggests that it is higher than has been supposed robably even this estimate is too low for it omits atients who lived for more than eleven years without eeding medical attention. Furthermore CAMPBELL nd KAUNTZE[2] now claim a congenital origin for ome cases of aortic stenosis—*a lesion still generally* egarded, at least in young people, as rheumatic heir reasons are chiefly clinical 40 cases, 31 of hich they believed to be valvular because of radiographic evidence of calcification, included 20 with haracteristic signs in infancy or early childhood, hen rheumatism is rare, and a further 17 with uch signs before adolescence In 5 of these patients here was a history of rheumatism, but only in 1 id this precede recognition of a murmur Again, here was no evidence of mitral stenosis in any f these cases nor was the clinical course like that f rheumatic heart-disease Other signs suggesting congenital origin were poststenotic dilatation of the orta soft aortic diastolic murmurs and evidence of ardiac hypertrophy with little enlargement of the eart. Cardiac function was good, but some of he patients died *suddenly At necropsy in such* ases KARSNER and KOLETSKY[3] found inflammatory esions, but CAMPBELL and KAUNTZE suggest that hese may be secondary and should be reassessed n the light of the clinical evidence

Almost all congenital *malformations* of the heart re thought to result from arrested cardiac development in the early months of intra uterine life Even solated defects such as infundibular pulmonary tenosis and subaortic stenosis can be explained n this way and the same explanation probably holds also when the obstruction is at the level of the valves, despite some pathological evidence for the earlier hypothesis of fœtal endocarditis[4] The cause of the developmental failure is not so clear, but both abnormalities of the uterine environment and inherited predisposition are known to be important. The classical observations of GREGG,[5] who found 44 cases of congenital heart-disease of one kind or another in 78 children with congenital cataract following maternal rubella in early pregnancy, have been amply confirmed SWAN et al.[6] found 21 cases among the children of 01 mothers who had had rubella in the first three months of pregnancy, and similar observations *have since been described repeatedly*[7] There is nothing to suggest that other virus infections, such as measles and poliomyelitis have the same effect, possibly the reason is that these kill the fœtus Patency of the ductus arteriosus seems to be associated with fœtal distress at birth suggesting that prolonged anoxia may play a part in its causation The children of women who have had repeated still births or miscarriages seem to be rather more apt than others to have a congenital disorder of the heart Inherited characteristics are always difficult to prove unless they behave as dominants or produce common *or benign lesions* The *association of heart-disease* with other inherited defects, including mongolism and arachnodactyly is well known and sometimes more than one member of a family has a congenital cardiac lesion COURTER et al[8] found reports of *03 families in which more than one member had* any of several types of lesion but particularly atrial septal defect CAMPBELL[9] found that of 110 consecutive patients 7 had affected siblings—more than would be expected by chance In Birmingham McKEOWN *et al*[10] *investigated the families of 431* cases drawn from 425 fraternities, and found 6 affected among 342 siblings born after the propositus this is a proportion of 18 per 1000 which is considerably greater than that in the general population They could *not estimate the likelihood of siblings having* similar lesions, but on the whole thought that they tended to do so The proportion of affected parents was probably no greater than that in the adult population Two first-cousin marriages each produced a child with dextrocardia (*thus supporting* COCKAYNE's[11] view that visceral transposition is due to an inherited recessive gene), while one second cousin marriage produced a child with œsophageal atresia and cor biloculare

This rather *incomplete* picture would perhaps be made clearer by a study of twins but there can be little doubt of the importance of genetic as well as of environmental factors The prognosis for patients with congenital heart-disease is bad in the Birmingham *series, of every 10 affected children only 3 reached* the age of ten years Surgery has improved the chances of these patients, but even so the outlook is gloomy enough to make us want to know more about causation

Antibiotic Enterocolitis

IN *this issue Dr* GARDNER *reports two cases in* which severe and ultimately fatal enteritis unexpectedly and suddenly developed during the administration of aureomycin or oxytetracycline (terramycin) to patients whose primary illness was unrelated to the gastro *intestinal* canal. In both cases pure and abundant growths of antibiotic resistant coagulase positive staphylococci developed in cultures from the intestinal and respiratory tracts the gram negative bacilli characteristic of the normal fæcal flora were conspicuously absent In the U.S.A. and France

similar cases have been reported,[1–4] and clearly we must examine the facts surrounding this dangerous complication of antibiotic therapy

Oxytetracycline and aureomycin are the antibiotics especially implicated, but FAIRLIE and KENDALL[2] observed the same type of enteritis in patients given a combined course of penicillin and dihydrostreptomycin by intramuscular injection. Obviously there is need for discretion in the choice of antibiotic, to prevent postoperative infection or to treat an established infection, where the patient's general condition is much reduced either by severe or long-continued infection or by such states as malnutrition and chronic alcoholism For example, weighing risk against likely gain, the powerful bactericidal effect of streptomycin and penicillin is essential for the successful treatment of endocarditis caused by *Streptococcus fæcalis*, since the infection is not otherwise curable the hazard of this particularly powerful combination is justified But it is doubtful whether such a combination can justifiably be given to prevent postoperative infection The "broad-spectrum" antibiotics—aureomycin, oxytetracycline, and chloramphenicol—have obvious attractions as prophylactics in that they are given by mouth and protect against so many organisms, particularly those of the intestinal tract But these drugs rather often provoke some gastro-intestinal disturbance, and it is a mistake to suppose that the symptoms are always either mild or transient At the recent Washington symposium on antibiotics[5] the discovery of a new antibiotic, tetracycline ('Achromycin'), was announced The chief advantage claimed for it is that it causes much less nausea, vomiting, and diarrhœa than either of its near relatives, aureomycin (chlortetracycline) or oxytetracycline, with which it shares many properties If this is confirmed the new drug will indeed be welcome Meanwhile in choosing prophylactics it should not be forgotten that succinylsulphathiazole by mouth and penicillin by injection provide good cover with little risk, and that moderate dosage over a short period is likely to be effective Altogether it seems that much current practice is based on unduly pessimistic estimates of the risk of sepsis complicating operations, with the result that patients are being needlessly exposed to real dangers by over-insurance against complications which are improbable and which can readily be controlled by prompt treatment with antibiotics There can be no substitutes for a sound aseptic technique and for watchful care during convalescence, these will contribute far more to the safety and welfare of patients than a carefree enthusiasm for hearty doses of the latest antibiotic Before the era of sulphonamides and antibiotics sepsis had become a relatively rare complication of deliberate operations

We normally live on peaceful terms with our intestinal bacteria, and it seems almost ungracious and certainly naïve to disturb their balance suddenly in preparing for a surgical operation We cannot by giving known antibiotics eliminate all forms of living micro organism from the intestinal tract, and we must expect that suppression of the species sensitive to the chosen antibiotic will favour proliferation of those which are insensitive We still know little of the complicated influences governing the ecology of the bacterial population of the intestine, but common sense suggests that it may be best for the patient to weather a surgical crisis in company with the organisms with which he has come to terms Perhaps staphylococci are not the sole cause of the enterocolitis reported by Dr GARDNER and others, but many coagulase-positive staphylococci produce enterotoxin and may give rise to sharp outbreaks of food poisoning. Owing to our own activities, staphylococci in hospitals are now largely resistant to the antibiotics in general use, and it has been suggested that erythromycin, as it becomes available here, might be reserved for cases of staphylococcal enteritis Such restraint, however, would not be in keeping with the general popularity of new antibiotics, and in any event erythromycin resistant staphylococci appear very readily In the Washington symposium,[5] LEPPER referred to a hospital in which after five months' use of erythromycin the carrier-rate of highly resistant strains reached 75% The remedy seems to involve, firstly, educating ourselves to use antibiotics sparingly, taking full advantage of other means of preventing surgical sepsis, and, secondly, undertaking careful and critical studies of the normal intestinal bacteria and of the influences, including antibiotics, which determine important changes in this richly varied population

Peripheral Neuropathies

FEW nosological problems can be more difficult than that of the peripheral neuropathies Rational classification is difficult because of the wide clinical variations and the complex pathological and biochemical findings[6] Accordingly in treatment the tendency has been to apply any remedy for which success has been claimed, regardless of the type of neural disorder

Clinically the disturbance may be peripheral, in the nerve roots, in the spinal cord, in the brain, or in the cranial nerves, but this variation only suggests varying susceptibility of the neuronal groups Pathologically, too, the findings vary enormously For instance, in the Guillain-Barré syndrome (infective neuronitis, infective polyneuritis, polyradiculoneuritis), SCHEINKER[7] was impressed by the pronounced swelling of nerve-fibres in the spinal roots and cord tracts and in the cranial and peripheral nerves, while LOWENBERG and FOSTER[8] described degeneration of the myelin in the peripheral nerves, spinal cord, ganglia, and brain stem FORSTER et al,[9] on the other hand, found that the central nervous system was not materially affected Such different pathological findings clearly reflect the differences in the clinical picture, they are no doubt due partly to differences in the temporal evolution of the disorder Biochemically a few features are now clearly defined JOINER et al[10] showed that neuropathy due to

in B_1 deficiency is associated with inhibition of yruvate-oxidase enzyme system, and THOMPSON[10] pointed out that abnormally high blood pyruvate s may be found not only in patients with neuro y associated with vitamin B_1 deficiency but also hose with toxic neuropathies due to lewisite, ic or other metals These substances are believed sturb the pyruvate-oxidase system by their attrac for the sulphhydryl groups of the enzyme elns. In the deficiency neuropathies (possibly iding some diabetic forms) it is reasonable to uister vitamin B_1 and in the toxic neuropathies ercaprol (BAL) which is believed to restore enzyme librium In the majority of neuropathies however e is no clear indication that either vitamin B_1 iency or intoxication is at work—and this seems apply also to the rare neurological affections ciated with porphyria and with carcinoma

he most common form is the Guillain Barré lrome, and it is chiefly in this group that the ous remedies have been assessed VAN HAGEN BAKER[11] have described their experiences in cases treated with a combination of vitamin B_1 dimercaprol They found that about half of e patients seemed to ' show improvement " and cluded that this improvement indicated that the drome was itself due to disturbance of the enzyme system Other workers have suggested an allergic basis emphasising the histological picture of œdema of the neural tissues leading to secondary myelin degeneration These days such a hypothesis leads inevitably to a trial of cortisone or corticotrophin (A C T H) Among others, BLOOD et al[12] and NEWEY and LUBIN[13] have reported dramatic improvement in the Guillain Barré syndrome after administration of 25 mg of corticotrophin intravenously over a period of 8 hours each day for 5–10 days Discontinuation of treatment was followed by relapse, but this was successfully countered by a further course In this issue Dr LIVERSEDGE and Dr LEATHER report a good response in a patient with polyneuritis associated with periarteritis nodosa This association is well recognised, and it seems possible that both disorders may be due to tissue hypersensitivity which may be primarily neuronal or due to affection of the vasa nervorum Apparently allergy may play an important part in the Guillain Barré syndrome, the sensitising agent is still unknown but this syndrome almost invariably follows some minor infection Furthermore the polyneuritis associated with measles mumps, diphtheria, and even porphyria might also be explained by this hypothesis. Though the evidence is still imperfect, the day may be approaching when neuropathies can be treated more rationally

CLINICAL RESEARCH BOARD

HE Medical Research Council announces this week membership of the Clinical Research Board, set up ccordance with the white-paper on Clinical Research Relation to the National Health Service[1] The board ointed for three years after consultation with the istry of Health and the Department of Health for tland has the following members

ir GEOFFREY JEFFERSON F.R.S. emeritus professor of rosurgery University of Manchester (chairman); Prof GALD BAIRD midwifery department University of Aber n; Sir HENRY COHEN department of medicine University Liverpool Prof E. C DODDS F.R.S., Courtauld Institute Biochemistry Middlesex Hospital London Sir JAMES ARMONTH, department of surgery University of Edinburgh f. A. J LEWIS Institute of Psychiatry Maudsley Hospital, ndon; Prof G W PICKERING medical unit, St. Mary's spital, London; Prof R. PLATT department of medicine, iversity of Manchester; Sir JAMES PATERSON ROSS, gical unit, St Bartholomew's Hospital, London Sir MES SPENCE, department of child health King's College wcastle upon Tyne and Prof. B W WINDEYER, Meyer in Institute of Radiotherapy Middlesex Hospital London. e chief medical officers of the Ministry of Health the partment of Health for Scotland and the Ministry of alth and Local Government in Northern Ireland will be essors to the board and the secretary of the Medical search Council will attend all meetings. Dr F J C erald, a senior medical officer on the council's headquarters aff will act as secretary

The board will be concerned with promoting whatever inical research needs to be organised on a national basis. t will aim to ensure that all fields of inquiry are ade ately covered, and will collect, collate, and distribute formation in order to reduce the time-lag between iscoveries and their application

TEETHING-POWDERS

AT an inquest last week the death of a child aged ten months was attributed to bronchopneumonia due to pink disease, itself the result of mercury poisoning following innocent overdosage of teething powder[1] Last year the Minister of Health, replying to a question in the House of Commons said that the indiscriminate use of teething powders containing mercury is clearly undesirable [2] This advice has been unheeded and teething powders containing calomel are still being sold to the public without adequate warning about their dangers.

In his article[3] last week Dr Farquhar described two more cases where mercury caused or contributed to death one child died from severe renal damage, apparently a similar condition to that reported by Wilson et al.[4] and the second showed many of the clinical features of pink disease The nephrotoxic action of mercury is undisputed and these reports alone are sufficient to proscribe the use of mercurials in infancy But the rôle of mercury in pink disease is not yet clearly defined: that the disease is a form of poisoning by or hypersensitivity to mercury has been strongly suggested by the work of Fanconi[5] in Switzerland and Warkany[6] in the U S.A They have shown that in many cases of pink disease there is either a history of mercury ingestion or inunction or an excretion of excessive amounts of mercury in the urine This is true also of reports from this country[7, 8] Australia[9] and South Africa.[10] These have demonstrated the interesting correlation between

the age distribution of the disease in various parts of the world and the differing mercury habits of the population. Fanconi has produced positive skin reactions to mercurials in affected children, while Warkany has drawn attention to the symptoms shared by pink disease and mercury poisoning. The beneficial effect of dimercaprol (B.A.L.) in some cases of pink disease also points to mercury as a possible cause.

On the other hand, many pædiatricians are unconvinced that mercury is a common cause of pink disease in this country, for various reasons. Often there is no history of mercury having been taken, and, when there is it is likely that it has been given as "home treatment" in the early stages of already established pink disease. Oliguria with a concentrated urine is typical of pink disease, so the finding of an excess of mercury in single specimens is not conclusive proof of an abnormal daily output. Fewer infants are now ritually purged with calomel, but pink disease is rather more common. Holzel and James[7] found more cases in an area where only 7% of infants regularly received teething-powders than in a neighbouring county where 37% had regular doses. As Pehu[11] demonstrated, pink disease tends to occur in epidemics, but it is doubtful whether the administration of mercury shows similar fluctuations. The natural history of pink disease is unlike adult mercurialism, nor does it accord with recognised hypersensitivity reactions. Finally, James[8] found that treatment of the mouth lesions with mercurochrome did not adversely affect the course of the disease. In spite of these potent criticisms, it is likely that mercury plays some part in some cases of pink disease—and there is certainly as yet no other very satisfying explanation of the condition. Recent alternative hypotheses, such as the endocrine approach of Cheek[12] and the psychosomatic basis of Leys and Cameron,[13] are not entirely convincing, so the student of pink disease may say, with Lady Blanche, "there's an unbounded field of speculation, on which I might discourse for hours."

Whatever the final conclusions may be, there is an immediate practical issue. Seven million teething-powders of the most popular brand are sold annually, some of them on medical advice. Each contains half a grain of calomel, which has no therapeutic properties superior to those of relatively harmless drugs. It is surely time that calomel was withdrawn from the formulæ of teething-powders.

NOCTURNAL MYOCLONUS

MANY people have occasionally experienced the sudden start which may momentarily wake them just as they are dropping off to sleep. Jack London had a pleasing phylogenetic explanation for it in one of his novels. He suggested it was the vestigial remnant of the protective start which roused man's arboreal ancestors as they were about to fall from their sleeping perch to the dangers below. In some people these nocturnal jerks may be frequent and repeated, and for these cases Symonds[14] proposes the term nocturnal myoclonus and suggests that this is an epileptic variant. Of 5 cases which he describes in detail, there is suggestive evidence in 2 of other epileptic manifestations, while in 2 others the setting of attacks or their precipitation is reminiscent of the type of reflex myoclonic epilepsy well known to neurologists.

The mechanism of the generalised reflex myoclonic jerk is of considerable physiological interest. It must represent the sudden momentary discharge of some centre having access to widespread motor pathways, and is peculiar amongst epileptic phenomena in showing no change in consciousness and ending abruptly almost as soon as it begins. This latter feature may suggest an active inhibitory element, such as is seen so prominently in the cataplectic attack, itself sometimes precipitated by sudden surprise. Neurophysiologists are now familiar with subcortical centres, such as the mid-brain reticular formation, which mediate widespread motor inhibition or discharge. It may be that nocturnal myoclonus represents an abnormal discharge from such lower levels where functional representation is less differentiated and where inhibition and excitation are more closely juxtaposed. But the evidence for regarding *all* such cases as basically epileptic does not at present seem very great. It is perhaps still a matter of clinical impression; which, when properly interpreted, can supply the hypothesis which adds value to further observations.

RENAL TRANSPLANTATION

THE transfer of tissue to a new site in the same animal or patient is described as autotransplantation; the transfer of tissue from one subject to another of the same species as homotransplantation. Autotransplantation of skin and bone is an established part of surgical practice; and homotransplants of bone, artery, and cornea have been successful in many patients. There is doubt, however, as to how far homotransplants of bone and artery are actually viable; they may merely form an appropriate scaffolding for new tissue growth. Corneal grafts are in rather a special category, since they contain very few cells and are relatively or completely avascular; and this reduces the likelihood of the immunity responses which destroy the generality of homografts.[1] Rather different problems will have to be solved before homotransplantation of complex organs, such as the kidney, becomes practicable; but increasing skill in vascular anastomosis, and increasing knowledge of the structure of immunity in different individuals of the same species, allow us to hope that these will be solved. Meanwhile, bold attempts are occasionally made to anticipate the future.

In December of last year, a boy of 16 fell from a scaffolding and ruptured his right kidney; after this had been removed at an emergency operation it was found that his left kidney was hypoplastic, and not forming urine. When he had been anuric for a week, his mother insisted that one of her kidneys should be grafted into the patient; and this was done, the kidney being ischæmic for only 55 minutes. Urine formation began at once, and in a few days red cells and protein disappeared from the urine. The blood urea fell from over 400 mg. to less than 100 mg. per 100 ml.; and the urea clearance of the grafted kidney ranged between 8.4 and 14.2 ml. per min. The urine volume was over 3 litres when the blood urea was high, and at this time there was considerable electrolyte loss in the urine; later, the urine volume fell with the blood-urea, although the urea clearance remained constant—findings of great interest in relation to Platt's hypothesis that the polyuria of renal failure is largely an osmotic diuresis.[2] After 16 days the patient was allowed up, and some protein appeared once again in the urine; on the 21st day after grafting the flow of urine stopped abruptly, and the kidney swelled to twice its size; and the patient died after a further period of anuria. At necropsy the kidney showed cellular damage in both glomeruli and tubules; there was also vascular damage, with hyaline necrosis; but the blood pressure had been raised for some time before death, and the vascular changes may have been related to this, and not to the renal "apoplexy" which happened so suddenly on the 21st day after grafting.

here was a progressive rise in the gamma-globulin action of the patient's plasma proteins this supports e suggestion that the renal catastrophe was due to rmation of antibodies to the foreign kidney but there as no deviation of complement

Reporting this case Michon et al.[3] point out that the dney perished despite the satisfactory vascular anasto oses the absence of infection and the close relationship f donor and recipient. They attribute the destruction f the kidney to an immune reaction, pointing out that e time taken for this to develop is comparable to that und in homotransplantation experiments from the oneer work of Carrel[4] onwards. Their observations o show however, that a grafted kidney can function efully, though not normally—a limitation which pplies even to autotransplanted kidneys in dogs[5]

Attempts have also been made to transplant kidneys to patients with chronic nephritis[6] Almost all have iled sooner or later, commonly because of infection voured perhaps by the use of cortisone or corticotrophin, ven with the object of suppressing immunity mech nisms. Some hope, however, is to be had from Miller's[7] port of the survival of one transplanted kidney for ½ months, after which the patient died because f his persistent hypertension and not because of renal ilure, the blood urea having fallen to 33 mg per 100 ml t present it seems that a renal homotransplant is most but not absolutely certain to be destroyed herein lies the stimulus to further effort, and perhaps r the moment this should be experimental rather than inical, lest vain hopes be raised

CORTICOTROPHIN AND CORTISONE IN DERMATOLOGY

The Ministry of Health recently announced[8] that pplies of corticotrophin (A.C.T.H.) and cortisone are to e made available for the treatment of a limited number f diseases, including certain dermatoses Up to now pplies of these hormones for dermatological use ave largely been distributed by the Medical Research ouncil. The report of the panel of dermatologists o whom their use was entrusted has not yet been ablished.

In a summary of four and a half years experience 'Leary and Erickson[9] describe two main categories of kin disease in which they consider the use of cortico rophin and cortisone indicated. One group comprises therwise fatal disorders, notably pemphigus vulgaris and stemic lupus erythematosus here treatment may have o be sustained for years, although there may be periods f remission when it may be temporarily suspended On the other hand, in self limited but violent skin reactions uch as severe contact sensitisation dermatitis or acute drug eruptions a few days treatment with the hormones may suffice. O Leary and Erickson stress that the great majority of patients with skin disorders do not benefit from this treatment. The usual general contra-indications for their use apply equally to skin diseases, and, in addition acrosclerosis is a special risk, 6 patients with this disorder died of "cerebrovascular accident associated with severe hypertension and renal disease after treatment with cortisone. The success of treatment may be limited by irreversible damage for example in lupus erythematosus the impairment of cardiovascular and renal function imposes particular difficulties in the use of these hormones and convulsive seizures may be increased in frequency[10] and necessitate interruption of treatment.

When long-continued use of corticotrophin or cortisone is necessary, it is often difficult to devise a dosage which will control the disease without producing serious side-effects This danger cannot be overcome by the local application of cortisone which is of no value when used in this way There is some hope that Compound F may be effective by local inunction[11] it does not seem to cause systemic effects judging by the number of circulating eosinophils when given locally[12]

Corticotrophin and cortisone are not curative in any skin disease in the sense that they abolish the underlying pathological process. They appear to modify the body's reaction to the process but unless the cause is removed the disease continues as it were 'underground.' Thus, in systemic lupus erythematosus, the laboratory can detect signs of activity although the patient is relieved of symptoms In epidermal sensitisation, eczema may be suppressed but patch testing shows that the hyper sensitivity persists Moreover, not all cases respond and they may in fact grow worse during or after stopping treatment It is therefore obvious that useful as these substances may be in the suppression of symptoms, they are by no means the answer to the dermatologist's prayer

THE MOTHER AND THE NURSERY SCHOOL

The idea that civilisation begins in the nursery is not new but the corollary—that the mother as prime civiliser needs every tool in the way of intelligence education and skilled help that Nature and the Treasury can afford her—is as yet only dimly apprehended. She can however get skilled help of a particular kind from the nursery school The W H O Unesco advisers on mental hygiene in the nursery school, who met in Paris in 1951 and whose report[13] has now appeared, are careful to draw a distinction between the nursery school proper, which provides for a few hours daily, an extension and enrichment of those opportunities for development which the child in his early years gets in his own home, and the day nursery which has to provide substitute maternal care throughout the day for infants and young children whose mothers are out at work or for other reasons unable to look after them. It is true that many day nurseries provide some preschool education on nursery school lines but this is usually a secondary function. The child attending a true nursery school spends most of his time with his mother the child in the day nursery may spend as much as 12 hours of the 24 away from her The day nursery then ought to be planned to give him as good a substitute for maternal care as possible and also to offer him the chances provided by the nursery school The same staff, the group say, cannot be responsible for both those who give care throughout the day should be relieved, during a part of the day by those who give him preschool education

The years between infancy and school life are packed with emotional experience During them the child is normally building up a concept of his self separate from reality (as he conceives reality) but having a relationship with it. He also develops a personal relationship with another person—his mother—and through this experience learns to form a personal relationship with someone other than his mother This person is often the nursery-school teacher and through her he will develop the capacity to form relationships with several people, including those of his own age She must therefore be a person of special qualities, and carefully prepared for her

job someone at ease with herself, with warmth, kindness, and objectivity—not someone who has taken up the work to satisfy her own emotional needs

Methods of training for this work differ in different countries, here it is usual for girls leaving school to enter as nursery school student nurses, some go on to become heads of nursery schools while others use this experience as a preparation for a nursing training In some other countries, however, the candidate trains as a teacher, and only decides towards the end of her course in what kind of school she wants to teach She thus has the advice of her teachers in making her choice, and if the choice turns out to be a wrong one she can change to some other branch of teaching, since her qualification is valid in any kind of primary school

A successful nursery-school career, the group say, depends primarily on "the teacher's own understanding of children, developed through a continuous experience with them during her own period of growth" Unfortunately this experience is not as common as it used to be, and "many growing girls are unprepared for the emotional responsibilities of motherhood" The reformers of the last century who prised open the gates of education for girls were obliged to direct them along the road trodden by boys that way only lay equality of academic opportunity An unforeseen result of this has been that the ancient and respectable career of childbearing and child rearing has acquired an amateurish aspect no diplomas are given, and the training—now that families are small—is deplorable "Only too often," the group say, "the young mother's first baby is also her first intimate contact with a preschool child", and they do not suppose that domestic science and motherhood classes for school-leavers can fill the bill "Rather our educational system should make it possible for older girls naturally to take small responsibilities for younger children, and particularly for children of preschool age" The prime civiliser, in fact, should be given early and adequate experience of the sort of people she will have to civilise

RADIOGRAPHY OF THE MAXILLARY ANTRUM

IN 1891—the year after Rontgen discovered X rays—Scheier[1] reported on the value of radiography in the diagnosis of diseases of the nose and throat, but the quality of his films was poor and the outlines of the sinuses could hardly be seen Nowadays, however, technique is so nearly perfect that radiography is without doubt the most useful adjunct to the clinical diagnosis of antral disease

Burtoff[2] found that the radiological reports of maxillary sinusitis were confirmed by proof puncture or other operation in 86 out of 100 cases Ballantyne[3] correlated proof puncture findings with X ray appearances in a series of 75 cases of suspected antral infection Of 66 cases in which there were radiographic changes 57 showed evidence of infection on lavage Perhaps even more encouraging is the fact that in the 9 cases where there was no radiographic abnormality, the washings showed no evidence of infection This is important, for the same cannot be said of other methods such as transillumination, which may indicate that an antrum containing pus is completely clear In a further series of 206 cases Ballantyne and Rowe[4] confirmed the earlier findings Three main groups were distinguished the first group consisted of 10 cases in which the antra were completely clear on radiography, the second contained 88 cases in which the antra were completely opaque, and the third consisted of 82 cases with radiographic appearances of a thickened membrane On puncture, there was no naked eye evidence of infection in any of the cases that were radiographically clear, more than 8 out of every 10 that were opaque in the film gave positive findings on lavage, while in less than 1 in 10 of those with a "thickened membrane" pus or mucopus was found in the wash out It would thus seem that a negative radiograph of the antrum is pretty reliable

What causes radiographic changes in the antrum—is it a mucosal or bony change, or is it the presence of fluid? Why should an antrum be opaque in the absence of gross infection? Why are sinus radiographs less reliable in children than in adults? Is it possible to distinguish thickening of the membrane due to allergy from that caused by infection? Samuel[5] goes a long way towards answering all these questions An antrum may be opaque for many different reasons Inaccurate positioning of the patient may produce the appearance of an opacity in the antra, and certain anatomical factors may cause confusion, notably thickening of the bony walls in relation to the size of the cavity, thickness or honeycombing of the bones of the cranial vault, alterations in the slope of the normal antral walls, and overlying swelling of the soft tissues

The two factors most commonly responsible for mucosal thickening are allergy and infection A scalloped mucosal swelling, with the convexities directed towards the cavity, is likely to be allergic, mucosal thickening parallel to the walls is likely to be infective Thickening is usually greater in allergy and is often accompanied by enlarged turbinates, and polypi in the nose or antrum are nearly always allergic When the antrum is completely opaque, it is impossible to distinguish these two causes, but some help may be had from examining the other antrum, for seldom are both completely opaque If fluid fills the cavity it will be uniformly opaque, but when air is also present a fluid level is seen. Encysted fluid not under tension may form an apparent fluid level, but the absence of mucosal thickening should make one suspicious, and the lateral view will demonstrate the convexity of the "level" Thinning of an antral wall may be caused by pressure atrophy from cysts or tumours, but is also seen in the normal antrum with a well-developed alveolar recess pressure atrophy decalcifie the walls, normal thinning does not Malignant infiltration usually first involves the medial wall, but here it is not easily detected, infiltration of the lateral wall i relatively easy to detect but usually implies that th growth is advanced

A single radiograph can only show the state of th antrum at the time of exposure, the changes are ofte transient, and thus serial radiography may be essential. Radiography of the maxillary antrum only supplemen clinical examination, and should not be undertak indiscriminately, but an opaque antrum usually mea gross disease, and a clear one can nearly always be reli on as excluding it

THE WAVERLEY COMMITTEE

IN September the Ministry of Defence announced that the Government proposed to set up a small co mittee under the chairmanship of Viscount Waver F R S, "to review the arrangements for providing med and dental services for the Armed Forces at home abroad in peace and war" It has now been announ that the other members of the committee are Harold Boldero, F R C.P, Mr S R Dennison, Sir Tho Gardiner, Sir Arthur Porritt, F R C S, and General James Steele Mr E P Donaldson, of the Ministry Defence, is to act as secretary The committee me the first time on Dec 2

THE MALADJUSTED SCHOOL

W MARY BURBURY
M.A. Camb M B Lond D P.M
SENIOR LECTURER IN CHILD PSYCHIATRY AT
THE UNIVERSITY OF LEEDS

HE present situation of schools for maladjusted child seems so deplorable and so likely to discredit their ne that it requires discussion

THE PIONEER SCHOOLS

lthough a few voluntary schools existed before 1939 did good work, it was during and after the war, partly because difficulties arising during evacuation w public attention to problem children, that the of such schools became, as it were, fashionable It taken up by the Ministry of Education and the l education authorities and was further stimulated by 1944 Act and the Curtis report. Partly because of exigencies of the time but also I think because of k of informed opinion schools have been and are ng established without consideration of the basic chological situations involved, or of the needs they expected to fulfil, without specially selected and ined staff, and (most important of all) without vision for treatment.

he first schools were started and developed by husiasts who, whatever the errors they made and atever the emotional background of that enthusiasm least brought to their work ideals warmth and a ire to understand. But as seems to happen some- es, statutory provision, by obliging the local authori to set up such schools or hostels and by limiting ir right to use (and stressing their responsibility if y use) independent schools—thereby suggesting that se are less good—has made it seem that the only portant facts are buildings staff school equipment and ng facilities. That this group of children have special eds and that since they are sick children their first ed is for treatment, seems to be overlooked.

The general public have criticised the voluntary ools for maladjusted children on the grounds that they erfere with their own convenience and rights as zens. Their objections to them derive partly from me of the more glaring errors of the pioneer school d partly from the disturbance caused in a neighbour od by antisocial behaviour the difficulties resulting m mixing of the sexes, especially among adolescents, d a well founded belief that too much freedom is not psychological antidote for earlier over repression, and at the amount of liberty that can be given to any child thout engendering anxiety and hence licence is ited. School inspectors too have criticised these luntary schools on grounds of educational inadequacies, metimes being evidently unaware of the psychological nciples which must be applied in dealing with these ildren. Matters have been little, if at all, improved by e recent provision that such a school should only be ed if the local authority is satisfied that it is suited the child, and that the child is benefiting from the ucation received there One authority felt that this ovision was *satisfactorily fulfilled by asking me to see* child whom I had never previously seen, attending a hool of which I had no knowledge whatever When I ked permission to visit the school, the authority's presentative expressed the view that the school was no concern of mine'

STATUTORY SCHOOLS

Alongside these voluntary schools the local authorities n schools have developed. These so far as my experience and knowledge go, show little sign of profiting by the earlier experiments Of all the authorities with whom I have discussed this problem, only one clearly expressed the opinion that a school should neither be opened nor kept open in the absence of good psychiatric help What seems to be insufficiently faced is that these *children are sick* by definition the schools are established for the care and treatment of the emotionally maladjusted—a term which if it means anything means the psychologically sick. No one sending a sick child to hospital for long term treatment—because he has, say tuberculosis, or needs lengthy orthopædic treatment—would question that his medical treatment must take precedence of his educational progress (though we have come to understand that schooling for such children is valuable both in itself and as part of the treatment) Nor does anyone doubt that informed medical decisions on the education of the backward must be accepted, though of course the opinion of experienced teachers handling such children may influence such decisions. Indeed, it is recognised that teachers for such children need to be specially selected, and given special training for this difficult work Yet none of these things seems to have been accepted in the case of psychologically disturbed children even though they are regarded as sufficiently disturbed to be unsuitable for outpatient treatment in child guidance clinics, and to take their places in ordinary schools

Nor has there been any real attempt to select staff Psychologically disturbed people, because of their own disturbance often have a sympathy with such children and are attracted to this work; but, also because of their disturbance they cannot furnish the stable background so essential to the child's further development. The other group of teachers, or would be teachers, who appear in such schools tend to be those who for lack of training or capacity are unable to get or keep places even among ordinary ' children Of course there are brilliant exceptions. Nevertheless one headmaster recently said to me I spend as much time trying to sort out the problems of my staff as I do those of my children

SELECTION FOR PLACES

Selection of children for the schools seems to be based mainly on expedience Thus the Ministry insists repeatedly on the separation of boys from girls—which, whatever the advantages of coeducation seems to be wise in view of the acute sexual problems which are commonly a part of emotional instability and maladjustment Heads of schools accept the importance of some selection on the basis of age-groups and intelligence and many now recognise the value of a full child guidance report—from the psychiatrist the psychologist, and the psychiatric social worker (who also reports on the home) Nevertheless, it is still possible to find in one and the same school the following types of children the relatively normal child, admittedly sent because of difficult home surroundings and only because of these the antisocial child, destructive and pilfering of the affectionless ' type, sent in apparently, because of his nuisance value, the dependent infantile child, of neurotic make up and, mixed with these more than one who suggests early psychosis among whom may be one of really dangerous, violent tendencies. Obviously it is difficult, if not impossible to run any school satisfactorily with such divergent and conflicting types. Because of the shortage of places children are sent where there are vacancies and, partly because of our lack of knowledge the suitability of the school for the child or the child for the school plays very little part in the placement.

SOME PROPOSALS

Destructive criticism is notoriously easy and it seems proper, therefore, to offer some tentative constructive ideas—though those of us who have worked with disturbed children know how often experiments need modification in the light of further experience

First, at the back of each group of such schools there should be a hospital unit, adequately staffed by psychiatrically trained personnel Interchange between the hospital ward and the school should be easy, and the hospital ward might well act as a diagnostic centre as well as a place for treatment Such a centre could send out its young patients into the schools when they were fit, and could take back into the wards any who proved unable to stand the stresses of school life Teachers might be allowed to come into hospital to instruct individual children or very small groups At the other end of the scale, the school should have a hostel for children ready to try ordinary school life, and for adolescents ready to try a job, but both as yet unready to return to their own homes A holiday centre or camp is also needed for children unable to return home for holidays, either temporarily or permanently The natural centre for such an experiment would be a university, with a medical school, offering postgraduate courses to doctors specialising in child psychiatry, and also providing courses for teachers and social workers, particularly psychiatric social workers, entering this field of work A single hospital unit, of course, could provide the medical background for more than one school, and separate schools would be planned to serve children of different ages, different sexes, different intelligence levels, and different types of problem

The researches of Bowlby, and the experience of all child psychiatrists, suggests that the commonest basic factor in emotionally disturbed children is insecurity in the early home environment, however such insecurity may be caused On this basis, various forms of illness develop as a result both of the personality of the child, and of his individual experiences Such children therefore have a common basic need for a stable background A combined scheme, of the type outlined above, would mean that throughout treatment there would be a system of continuous and cohesive relationships, and the child would experience no sudden shocks or breaks likely to cause setbacks He would himself thus have the chance to develop a capacity for stable relationships The handling of a child by one therapist throughout his treatment, and his education in one school, with continuity of discipline, must have immense advantages A capacity for relationships can never be developed by a child who is repeatedly transferred from one unit to another, however excellent such units may be in themselves

Apart from their need for a stable background, maladjusted children vary considerably, and different cases require different handling, both psychiatrically and educationally Thus the aggressive, violent, antisocial child, and the timid, phobic one, are unlikely to help each other if mixed in the same group Moreover, teachers and therapists alike find that they do their best work with one group rather than another Thus, in the interests of staff and treatment, as well as of the children, careful placement is an important part of good treatment

Children are referred for residential treatment when it is felt that outpatient treatment would be inadequate to their needs This implies that they have personality problems, for the normal child whose environment only is the difficulty is presumably placed in a boarding school for normal children By the time a child with personality disturbances is of school age, his disturbances are so fixed that he needs direct treatment for them Good environment may help, but good environment alone will no more cure his condition than it will, alone, cure a tuberculous spine Both need their special types of individual and long term treatment We spend money ungrudgingly on the 24 hour daily treatment of spinal tuberculosis Psychological treatment is sometime equally lengthy, and it ought to be in the hands o the psychotherapist True, immediate symptoms may sometimes disappear without such long-term care, bu if we are to reduce the wastage caused by psychologica illness in adult life, we must deal with something mor fundamental than immediate symptoms

In many of these cases there are problems in th home, and since the child returns there sometime during the holidays, and in any event at the end of hi period of treatment, some help should be given at tha end Whether this should be done by a psychiatric socia worker (P S W) from the clinic which referred him, o by the unit described above, may be a geographica problem The P S W of a centre which draws patient from a wide area of the country may not be able to visi often enough to give real psychological help to th parents Moreover, the P S W of the referring clinic may already have made a good relationship with them whic it would be unfortunate to break, and such a relationship is a valuable link when the child comes home for shor periods or permanently Unfortunately this kind o work is sometimes overlooked, mainly because of th demands on the service and the lack of workers, bu sometimes because the value of the P S W as a lin between the home and the school has been insufficiently understood

Someone once said " It takes a neurotic to heal neurotic " , to which another made the reply, " True but it must be a healed neurotic " Probably only person who has himself suffered from this sort of difficulty has the patience and sympathy to want to help others i the same straits, but unless he has understood an coped with his own difficulties, they will stand in th way of his full capacity to help Not all teachers want t help, or are capable of helping, these children, an no one should be expected to try unless he does so wish since the work is exacting and difficult, and demand a personal generosity which exhausts even the mos vital Staffing should therefore be generous, hours short and classes small, but over and above this, teacher should have special training in the handling of the maladjusted child Postgraduate training for experience teachers who wish to specialise is now usual, and might well be extended to teachers interested in this type o work Specially trained nurses, too, are needed in the hospital ward they need experience in child psychiatry as much as the psychiatrist himself

The scheme outlined here would not only increase the value of the service, but would reduce costs by combining in one unit a number of projects, and ensuring that staff and premises were used more economically Such an experiment might well make the title of this article a misnomer

---

A SCHOOL FOR MALADJUSTED BOYS

SOMETIMES the dynamic forces which develop between parents and children rock the home The child becomes unmanageable, explodes into temper tantrums, runs away from home, truants from school, falls into delinquency, develops enuresis, or shows behaviour verging on the psychotic The parents make their own responses the mother may be worn out, anxious shrewish, or hysterical, the father irascible, brutal, or increasingly bored by the turmoil—which he escapes by going out to a public house In such a situation a diversion may have much therapeutic value

One way of creating a diversion is to place the child in a residential school for a time, with the aim of restoring him to his family when things have simmered down, and all parties have learnt a little more about the art of social living For in the event it is not merely the child but the whole family which is found to be maladjusted.

SURROUNDINGS

Bredinghurst at Peckham Rye a school for malad sted boys opened by the London County Council in 1948 conducted on lines dictated by this belief Mr W F emp, the headmaster has been obliged to develop s methods as he went along, for he had no model to py The school put at his disposal consisted of a omy house with good outbuildings, and four smaller ouses, all solidly built, standing in some 8 acres ground, at that time derelict The grounds are now easantly laid out with two large playing fields a zable pond with water lilies and goldfish, and plenty brilliantly coloured flowers, raised from seed in a ome made greenhouse

The school from the time it opened has taken its ll complement of 45 boys between the ages of six and fteen The main building holds the classrooms, a g playroom for winter and wet days and the clothing om, where boys are allowed to exercise personal taste the choice of pyjama stripes and shirts It also ontains the private quarters of Mr Kemp and his wife who supervises the clothing feeding and general are of the boys) There are also two cottages on the tate which provide a big room for art and pottery work well as another large room which is used for various urposes—cinema shows boxing and group therapy everal small rooms in these cottages are used by the aff for intelligence testing interviewing parents ffice work, and so on

The boys all live in the three residential houses, being istributed according to their age groups—little boys lder boys, and boys of intermediate age The houses re simply furnished but with an eye for colour Each f the bedrooms (most of which contain two beds) decorated in a different colour with beds and chairs ainted to match, and curtains and mats chosen to o well with the main colour scheme A bed and a hair and a share in a chest of drawers can be provided or almost any child in his own home, so the parents ave no reason to think that their child is enjoying uxuries they cannot afford. The boys eat in their wn houses, and the dining rooms too are decorated in leasant colours. The smaller boys, who need some elp sit at tables for 6 with one of the staff to encourage hem in the management of cutlery the older boys ave tables for 4 at which they can form their own groups. Each house has a playroom with some suitable equipment in the way of toys games, and books

The house matrons are experienced in looking after hildren, and some hold either a university diploma in ocial science or else the Home Office certificate in child are. They treat the children in a kind and motherly anner without trying to present them with substitutes or their own mothers Indeed the school does not ttempt, in this or any other way to supplant the parents, for the whole object is to get the child to form a better relationship with his own mother and father He orms with the school teachers and house matrons much the same relationship as a child in any other boarding school does with friendly and reliable members of the staff

THE PARENTS

It was early clear that the education of the child in a esidential school would not suffice, by itself to overcome his maladjustment the parents too, needed teaching; and they had to be encouraged to take their share in promoting his recovery In 1950 a psychiatric social worker was appointed As soon as it has been agreed that a child is to be offered a place in the school, she visits his home, for the purpose, as she explains, of telling the parents what the school is like This visit, of course besides putting her on a friendly footing with the family enables her to study the home conditions and the personalities of the parents themselves Later by her regular contact with the parents them with some of their own problems in child The parents learn that if the school their collaboration is essential Whenever are told this together—it is not left to the m the message on to a husband who at the out unreceptive, or even antagonistic, to the scho tions In the long run few parents have coöperate: for they usually mean well by their however incompetently they carry out their intentions. Parents are asked to accept certain obligations they are expected for instance to write regularly to their children to visit regularly, and if possible together and they are told that when the time comes for the child to go home for weekends one of them will be expected to come and fetch him on the Friday night and bring him back on the Sunday and that it is important not to break these engagements for trivial reasons or without giving warning Of the parents of the 150 children who have already passed or are passing through the school very few have failed to do their share in these ways and only about 5 have flatly refused to attempt it

PSYCHOTHERAPY

In the school the child is not only taught in the ordinary sense, but is given whatever psychological help he needs. As soon as he is able to profit by it, individual psychotherapy gives place to group therapy, which is proving very useful One of the psychiatrists attached to the L C.C holds regular sessions twice weekly in the school a lay psychotherapist attends five days a week, and an educational psychologist is also attached to the staff. Thus there is a full child guidance team working on the premises and in close collaboration with the school staff—an arrangement at present unique in this country The child's maladjustment can in fact, be studied at one and the same time from the psychiatric the educational, and the social aspects Case conferences are held by the staff every week when the child's progress is discussed and assessed

If the parents are young and willing to learn they too are asked to come and see the psychotherapist and as a result a good deal of teaching is given in the principles of mental health After the child's first few weeks in the school he is allowed to go home for every other weekend and the children all recognise this as a first step towards going home for good His parents fetch him on Friday evening and return him on Sunday evening when the headmaster the psychiatric social worker, and the house matrons are there to receive them, and to have a talk about the children The link between the school and the parents is thus very strong

THE CHILD'S PROGRESS

In school the children do a good deal with their hands —painting, modelling Meccano the making and baking of pots and the construction of glove puppets. Every child is taught woodwork in an out-house dedicated to the purpose, and he is allowed to take home his constructions—aircraft simple bookcases and the like—to keep at the end of the term Apart from this, the staff give much serious thought to the teaching of reading, for nearly all these children have great difficulty in learning to read However as soon as a child manifests an interest in books the teachers follow it up and help him to master reading by whatever method seems to suit him—phonetic, look and say or even the time honoured C A T cat system, which some children seem to prefer

Once a child is responding in the classroom, and is beginning to overcome his emotional problems, he is allowed to attend the local primary or secondary school and wears cap and blazer of that school like the rest. is recognised by the children as an advance in ds going home for good The school usually t s half the children on the roll every year, and in ive years since it was opened 99 have gone home oved—in most cases to homes which have also roved Some 80% of those who have been discharged or two years and over were going on satisfactorily at follow-up

It seems that Bredinghurst goes far towards fulfilling the criteria for schools for maladjusted children set out by Dr Mary Burbury on p 1251

THE WORK OF C I.O M S.

THE Council for International Organisations of Medical Sciences was founded in 1949, under the joint auspices of W H O and UNESCO (At first it bore the name of Council for the Co-ordination of Medical Science Congresses) By acting as a registry office for international meetings C I O M S obviates the clashing of dates, and it is often able to persuade organisers to group their congresses so that interested persons can attend more than one Thus a congress on cardiology has been arranged in juxtaposition to one on internal medicine, a congress on cancer was timed in conjunction with one on radiology, and psychiatrists were able to attend consecutively congresses on mental health and criminology as well as psychiatry

The Council has also organised a number of important symposia, often at the time of a congress In 1952 four of these were held on experimental diabetes, the pathogenesis of arteriosclerosis, cancer of the lung, and hæmophilia These informal international round-table conferences are of special value in that they may be held in distant centres which are not always convenient for the staging of a major convention A logical development from the international congress and symposium is the organising in the same place, immediately before or afterwards, of an international postgraduate course, so that full use can be made of the services of the world leaders of the specialty who have congregated The Council has now arranged several such courses

The Council gives financial aid to international congresses for the initial organisation and also for securing speakers who might otherwise be unable to attend [1]

PLANNING A CONGRESS

In September, 1952, a conference took place in Paris of key officers of recent international congresses, and their findings are included in an account of the planning and organisation of such meetings [2]

The first international societies came into being at the end of the last century More recently such societies have tended to develop into instruments of research, enabling men with different national backgrounds to work side by side

Thus the social side of a congress is as important as the scientific side "Congressists" should be encouraged to get to know each other early in the meeting There are many ways in which organisers can help to achieve this end Buffet suppers, for instance, are preferable to sit down dinners, because they allow of more mixing, while evening dress should be optional and receptions free so that no one need feel unable to attend

The Council urges that the international society responsible for a congress should determine the pattern of the congress and the main subject to be discussed, although obviously it is seldom possible for the society to work out all details and select all the speakers, much of this work is better left to the local committee, which must, however, take care that the host country does not appropriate more than its share of the programme The secret of good congress planning is to plan early, for all local organisers learn, often to their cost, that international correspondence is slow The establishment of national committees to screen all material offered to the congress is an excellent way of securing international coöperation.

The president or chairman of the local group and the secretary-treasurer are the key officers, but their exacting work can be greatly eased if subcommittees play their proper part the two most essential ones are the programme and the social-functions subcommittees. A competent secretarial staff should be engaged early on and at once be allotted adequate space, for near the time of the congress it is inconvenient to move a growing secretariat into new premises A stipendiary executive officer fully conversant with congress technique can be a boon to the organiser of a big congress, but he cannot have the same knowledge of the personalities of participants as has the amateur who elects to run the congress for his professional colleagues

Nowadays a popular form of congress pattern consists of principal papers from invited speakers ("rapporteurs"), followed by critical or even contradictory papers from other distinguished leaders who have enjoyed a preview of the "rapporteurs'" contributions, before general discussion is permitted An alternative is to have invited and proffered papers grouped appropriately and each followed by discussion. Discussion has been found to be at its liveliest, however, at open symposia, especially when these are not too large, here a given topic is discussed by a panel of experts before an audience which is entitled to take part in an exchange of views At all congresses, however, an opportunity should be given for all to speak, especially since at present some members are only allowed by their employers or government to attend if they contribute to the meeting The reading of papers in title only is to be deprecated, because some of these papers may deservedly provoke a good discussion If necessary simultaneous sessions should be employed to exhaust the agenda The suggested time for a proffered paper is ten minutes, with five minutes for a discussion 1000 words can be delivered in ten minutes, but each lantern slide, if explained, must be reckoned as the equivalent of 50 words

Abstracts are essential, for they not only enable national committees to evaluate the papers but allow of translation into other languages It is recommended that the closing-date for the receipt of abstracts, which should not exceed 200 words, should be six months before the congress

Visual aids, such as the cinema and television, should be encouraged, they help greatly to minimise the ever present language difficulty The scientific exhibition, or demonstrations, encourages direct exchange of information and the making of valuable contacts The trade exhibition, too, is valuable, for the renting of space can be an important and legitimate source of congress revenue.

The greatest anxiety and expense for the organiser is over interpretation For small meetings, and especially those confined to two languages, the consecutive technique is suitable and has the advantage of not requiring expensive equipment For big meetings, however, simultaneous interpretation, if carried out by experts, is to be preferred But the interpreters must not only be excellent linguists they must be experienced in medical terminology Indeed, they should study the papers in advance

C I O M S has valuable advice to offer on the more technical points of congress advertising, budgeting, enrolment, registration, and programme printing. Hotel accommodation is best left in the hands of travel agencies, but hostel accommodation and private hospitality should be provided and encouraged.

---

[1] C I O M S Bulletin 1952, 3 no 1–2 The editor's office is at Unesco House 19 Avenue Kléber Paris 16e Annual subscription 9s or $1 60 no payment required from universities medical institutes or medical organisations.

[2] Ib 52 3, no 3–4

A special section of the report deals with the psychology international gatherings Every effort should be de to make visitors feel at home, and interpretation uld be provided not only at the scientific meetings but at the formal parties and excursions. All countries uld have an opportunity of *providing* chairmen and ing speakers. While not all may agree with the ous anthropologist who said that the makings of a d congress are music flowers and flags, most will nowledge that its success does not depend only on the ntific fare.

OTHER WORK OF C.I O M.S

The funds of C I O M S are derived from W H O sco, and the supporting societies. Half of the enue goes on grants for congresses and a fifth is roted to financing symposia and advanced courses w projects are envisaged by the Council, which now is ready to undertake greater responsibilities in the d of international medical science For instance, this r it has published a directory of the international anisations of medical sciences.[3]

The first part of the directory lists all international non ernmental organisations under subject headings. The ond part gives the national associations affiliated to each rnational organisation.

It is also responsible for the setting up of an inter tional commission on anatomical nomenclature and gave financial support to a similar body on cancer menclature. At present it is engaged on the mpilation of an anthology of psychiatric usage, while ently it, convened a meeting of senior executive icers of national research organisations to discuss the ruitment training, and careers of research workers the medical sciences But perhaps its most ambitious dertaking will lie in the direction of trying to egrate medical bibliography and literature and more rticularly indexing and abstracting A joint meeting the C.I O.M S UNESCO and W H O is to be held ortly to discuss medical documentation ' and to termine which problems are suitable for international tion and in particular for action by C I O.M.S

WELLCOME RESEARCH LIBRARY

Development at the Royal Society of Medicine

ON Dec. 4 Lord Woolton in the absence owing to illness the Marquess of Salisbury opened the Wellcome search Library of the Royal Society of Medicine

Sir FRANCIS WALSHE, F R.S the president of the ciety paid tribute to the foresight and generosity the Wellcome Trust It was a remarkable achievement r a small body of private people to establish a library over a quarter of a million books and to provide for s maintenance, growth and services out of their own sources. But the library had outgrown the society s rength and the gift of £125 000 from the Wellcome rust was timely

Sir HENRY DALE O.M , F R.S chairman of the Wellcome rustees and a former president of the society recalled ow the trustees *first helped the society with a gift* f £30,000 for additional library accommodation after e second world war Since then they had given a rther sum of £45 000 and for the next ten years the rust was going to pay the subscriptions of some 300 Vellcome associates, chosen among young graduates ho would not otherwise be able to afford the sub ription. Many of those already elected were young rseas graduates studying under the British Post graduate Medical Federation Though a permanent ution had not been found for all the problems which ed the society Sir Henry was sure that the library which was a national and imperial posse be allowed to be lost.

Lord WOOLTON was impressed that occupants of chairs " used the library o that provincial members borrowed 80 000 year *With 5000 volumes a year being adde* see there would be difficulties ahead The Govern ment is much concerned that the findings and records of scientific advance should be made as widely available as possible through the adequate service of technical libraries, ' he continued ' The Lord President s office is considering various ways of meeting the present specialist library requirements " The library would become an increasing strain on the resources of the society already it was costing about £25 000 a year It might well be that before long the society would wish to consider associating itself with other more general schemes for the supply of scientific literature which the Govern ment had in mind. It seemed inevitable that the many interests in this field must agree to collaborate if the public needs were to be met within the financial resources, not only of the society but of the country Any vast project for a new national medical library was bound to be extravagantly and even impossibly expensive Collabo ration was better than competition and the Government would welcome the opportunity for discussion when the time was ripe

A vote of thanks to Lord Woolton was proposed by Lord WEBB JOHNSON chairman of the building com mittee and afterwards Lord Woolton and the guests inspected the new library

The architects are the late Mr J J Joass, F.R.I B.A. (who designed the original building) and Mr Leslie Watson, F.R.I.B.A

HEALTH RESOURCES IN THE UNITED STATES

THE Brookings Institution has been responsible for a number of long term studies on health and welfare in the United States. Anyone who doubts the value of statistical inquiries will do well to read a study from this institution on health resources.[1]

This investigation was undertaken with several objec tives in mind including the ascertainment of the extent of health resources, the description of major private and public health programmes, and the establishment of a basis for further study Dr George W Bachman and his team have divided their survey into three parts concerned with (1) the health of the nation, as shown by vital statistics (2) the personnel in the health services ; and (3) these facilities and services

STATISTICS

Between 1900 and 1950 the death rate dropped nearly 45% and life expectancy increased almost 37% The death rate for infants under 1 year dropped from 162 4 per 1000 live births in 1900 to 31 3 in 1949 The investi gation shows clearly the effects of increasing age for more than half the hospital beds in the United States are for long term chronic illnesses The diseases in respect of which the death rate has increased are primarily those of middle and later life

Returning for a moment to the infant mortality rate for every 1000 babies now born some 130 live who would have died fifty years ago It is also known that of the thirty or so deaths which *did* occur among those babies, at least a fifth were preventable in the light of present knowledge—in some areas of the country infant death rates are consistently at least a fifth below the national average, while in others they are consistently above the national average.'

---

[3] Ibid 1953 4 no 1-3

[1] Health Resources in the United States Personnel Facilities and Services. GEORGE W BACHMAN and associates. Washing ton, D C Brookings Institution. London Faber & Faber 1953 Pp 344 36s.

s, however, in the variations in level of health by rict, sex, and colour that the statistics are most vealing Non-white males, for example, have a much higher death-rate for vascular intracranial lesions, chronic nephritis, tuberculosis, diseases of the respiratory system, syphilis, and accidental death Non-white females also have high rates for the same conditions, except accidental death The Southern and South-western States have the highest mortality-rates, and in relation to population they have the fewest hospital beds and medical personnel The three northernmost New England States—Maine, New Hampshire, and Vermont—have a high percentage of old people in their population and a relatively low birth rate

It would be interesting to know what some of our maternity and child-welfare experts would say of the following conclusions

> "In the great majority of cases, births which take place in hospitals are less likely to result in death to either mother or infant The hospital delivery to some extent reflects a total pattern of care or a non hospital delivery reflects the absence of that pattern mothers who give birth in hospitals are more likely than others to have had some prenatal care and hence are less likely to be delivered of stillbirths, they are more likely to receive continued medical care, with less chance of death to the infant in the first year of life"

It is also noteworthy that over one-tenth of all infant deaths in 1949 occurred within the first hour of life, and the data on urban first hour death-rates indicate a sharp difference in mortality risk for babies born in hospitals and babies born outside of hospitals, even though in the United States as a whole some 95% of all live births in 1949 were attended by a physician Indeed it is in the use of midwives that the greatest difference between the U S.A and this country is evident In thirteen States in 1949 the proportion of live births delivered by a midwife was less than 0 5%, and in three States none was so delivered In one State—Mississippi—the figure was 20 1%

In the Pacific States of Washington, Oregon, and California the percentage of infants born in hospital reached the extraordinary figure of 98 6 in urban areas and 97 1 in rural areas The study of maternal mortality statistics also brings out clearly the differences between rates for non-whites and whites "Among the whites about one woman age 20 to 24 died as the result of pregnancy per 2000 live births, whereas among the non whites the ratio was about one in 500" The death-rates for infants of 1–12 months were 8 7 per 1000 live births for whites and 17 4 per 1000 live births for non whites

The American investigators use the term "immature infants" to describe those born either too soon or with a significantly subnormal body weight, and it is estimated that 5–11% of live births fall in this category In 1949 the estimated death rate resulting from immaturity was 16 5 per 100,000 total population, making it one of the major causes of death in the nation The rates for non-whites were almost exactly double those for whites Nearly all the States require a record of the infant's birth weight on the birth certificate

The morbidity studies show that women are more often ill than men, and that chronic diseases are responsible for a very high proportion of the days of disability The figures also show that the disabilities of persons 65 years of age and over arise primarily from chronic illness In the words of the authors

> A country with an aging population must look forward to a constantly increasing aggregate number of persons disabled by illness for 12 months or more unless it can achieve success in combating chronic illness and the degenerative diseases '

In 1947 Blue Cross participants on the average went to the hospital more often than did the highest income class of whites in 1928–31 The factors involved are (1) increased hospital facilities, (2) transfer to hospitals of many cases previously cared for in the home, and (3) the tendency of insurance plans to encourage hospitalisation

PERSONNEL

Health personnel increased by about 40% between 1940 and 1950 Physicians increased by 17%, auxiliary nursing personnel by 98%, psychiatric social workers by 35%, psychologists by 166%, and sanitary engineers by 129%

> "One of the results of the uneven rates of growth [for different professional groups of health personnel] is that the major professionals make up smaller proportions of the health labor force than ever before Physicians, for example, who accounted for about 20 per cent of the 1940 total dropped to 16 per cent of the 1950 total Professional nurses also decreased, from 30 per cent. in 1940 to 26 per cent in 1950 In contrast to these decreases was the proportionately large gain in auxiliary nursing personnel, from 21 per cent. of the 1940 total to nearly 30 per cent of the 1950 total"

Of the *physicians,* 36% are general practitioners, 11 4% are general practitioners with part-time specialties, and 27% are full time specialists "Full time" in this connection means those whose practice is limited to a specialty Between 1940 and 1949 the number of full time specialists increased by 70%, while the proportion of general practitioners, including part time specialists, declined by about 13% The median age of physicians in 1948 was 44 4 years

In the United States there are 86,870 *dentists,* of whom 95% were in active practice in 1950 Only 3 1% of these were in federal government service Recognised dental specialties include orthodontics, pædodontics, periodontics, and prosthodontics, in addition to oral surgery, oral pathology, and public-health dentistry The mean age of dentists was approximately 48 years, and, although the dentists in the year sampled (1949) were older than those investigated in 1940, "continual improvement in techniques and increased use of dental hygienists and other assistants probably resulted in greater productivity"

The most dramatic changes are in the "*other health personnel,*" such as dietitians, laboratory technicians, medical record librarians, medical social service workers, occupational therapists, physical therapists, practical nurses, and X-ray technicians The over all increase in the group described under this heading is 70% in the years 1940–50 The vacancies in the eight categories numbered almost 47,000, with an estimated additional 77,000 needed in the next five years

Mention has already been made of the decline in *midwives,* their numbers dropped from 62,000 in 1923 to 18,925 in 1950 "The downward trend is attributable to the improvement in economic status of the population, enabling the use of medical and hospital services in preference to midwives, and the increased stringency of licensure" Nevertheless, "the midwife remains indispensable in areas where medical and hospital facilities are lacking" Most midwives practise in the South and among non white members of the population living in rural parts More than a third of all midwives in the United States were in Texas, Mississippi, and Virginia.

Dental hygienists numbered 7000 in 1950—an increase of 40% over those employed in 1940—and it is computed that at least 15% of the volume of dental services could be performed by hygienists

In 1950 75,000 *social workers* were employed, of whom 3000 were in the field of general medical care and 2250 in mental hygiene But in 1940–50, whereas the number of social workers in a general medical setting increased by only about 21%, the number of social workers in the psychiatric or mental hygiene setting quadrupled

Dietitians and nutritionists formed an important group numerically, but their importance is shown in another way, for the American College of Surgeons requires the food services in hospitals they approve to be administered by a person who meets the requirements of membership of the American Dietetic Association The function of public health nutritionists is defined as primarily to impart the principles of good nutrition to groups which in turn reach the public *tometrists*—i.e., specialists in the conservation and ovement of eyesight—increased by 71% in the ten years. e average case load of *chiropodists* in 1949 was 26 patients day for 220 days per year and an estimated total of 0 000 patients were treated during 1950

rhaps the most startling difference is in the status of *paths* for in 34 States and the District of Columbia graduates of colleges of osteopathy are eligible to be sed to practise medicine including drug therapy and ative surgery; in all but two States they are licensed practise obstetrics. An examination of the case-load a week in May 1950 showed that nationally there during that week 74 3 patients and 85 0 visits per opathic physician.

iropractic is a system of mechanical therapeutics con ng of a search for vertebral dislocations and, if found reduction by manipulation to relieve pressure on the es. *In 19.0 there were approximately 1500 chiropractors* ctive practice.

terinarians figure prominently among the health personnel the reasons are set out under four headings. Firstly veterinarian contributes to the control of animal diseases smissible to man; secondly he helps to maintain the ant high nutritional level of the American people by rolling the health of food producing animals; thirdly military veterinary services protect the health of the ed Forces by inspecting food for wholesomeness and ity and fourthly many fundamental discoveries in icine have come from the veterinarian—for example umarol and B C G

anitary engineers have doubled in number since 1940 about half are in public employment. Their duties include community planning the design and operation of water sewage, and industrial waste treatment plants and many other duties which in Britain fall to the medical officer of health and sanitary inspector

CARE OF THE AMERICAN INDIAN

One of the most interesting parts of this book is the section dealing with the care of the 400 000 American Indians. In 1789 the War Department was given control over Indian affairs, and the Bureau of Indian Affairs was established in 1824 From about 1832 Congress voted a sum of money annually for the prevention of disease among the Indians and in 1849 the responsibility for medical care was transferred to the Department of the Interior Since 1924 all Indians have had citizenship rights, but the federal government has continued to provide medical services for the indigent, and, because of their general economic conditions, most Indians are eligible Indian health problems are significantly different from those of the general population "The major problems are tuberculosis high infant mortality rates, diarrhea and dysentery, trachoma poor nutrition and dental caries.' The incidence of tuberculosis is very high indeed

In many instances the hospital staff consisted of only one physician per hospital and most reservations have only one nurse In many places, because of the language barrier, each public health nurse must have a driver interpreter

Public Health

Action against Smog

N interim report [1] by the Committee on Air Pollution Beaver Committee) was issued last week when Mr rold Macmillan Minister of Housing and Local Govern nt, made a statement in the House of Commons p 1200).

The report recommends the following main precautions be taken immediately

. Warnings to be issued by the Meteorological Office in ticular through the B.B C, of areas of normally high lution in which serious fog is expected to persist for at t 24 hours.

. Advice to the public and industry on action to alleviate mog and its effects Nearly half the smoke comes m house chimneys and about an equal amount from ustry

The committee urges that householders in large towns o depend on solid fuel and who normally burn coal uld lay in a stock of say a hundredweight of coke other smokeless fuel for use in periods of persistent . A mixture of coke and coal will burn reasonably ll and will greatly reduce smoke When persistent g is forecast

1 Householders who can use only coal should take special e not to make more smoke than can be helped. Fires ould not be banked up at night

2. Those who can use smokeless fuels should confine them lves to those fuels during periods of fog

3. Rubbish should not be burnt nor bonfires lit while the g lasts.

4. The general public should refrain from bringing motor hicles into densely populated areas.

5 Less smog' will find its way indoors and rooms will kept warmer, if draughts can be prevented

6 Elderly people and those suffering from chronic chest d heart conditions would be well advised to keep indoors d to rest as much as they can if the fog is very thick. If ey must go out they will find that a closely fitting simple ase mask, or even a woollen scarf wrapped round the mouth and nose, will give some relief by filtering out some at least of the solid contents of "smog

Regarding industry the committee recommends that smoke-control measures should be brought up to peak efficiency at once and checked frequently throughout the winter, that special efforts should be made to prevent heavy smoke when stoking and that a continuous check be instituted against the emission of dark smoke This check can best be made by installing a simple smoke-density indicator

The report remarks that it has been estimated that in the London smog of last December up to 60% of the smoke was due to domestic fires "It follows that a first immediate and stubborn obstacle to the reduction of smoke is the preference of the majority of people for traditional methods of heating The need for education and training in these matters is urgent and vital

'It is, says the committee simply a question of balancing the cost and inconvenience of enforcing a more efficient and scientific use of our fuels against all the advantages to be obtained in health, convenience and economy from a clear atmosphere This problem with all that is involved in a real attack on the menace of air pollution, is one which must be faced

Infectious Diseases in England and Wales

In England Now

A Running Commentary by Peripatetic Correspondents

MY gardening diary says that this is the time of year to take stock of the gentle art, to make a critical post-mortem examination of last season's living beauty, and to conceive the embryo of next year's brilliance But the diary reckons without the hazards of country life Paragraph by paragraph we punctuate the text with hollow laughter

Prick holes in the lawn to aerate the turf, says the diary, fill in the craters dug by the dogs, we reply Your lawn can be greatly improved by spraying with the new hormone weed-killers, runs the book, we could tell them a thing or two about hormones on grass, lovely green rings of succulent turf where the bitches have squatted, in fertile contrast to the withering squirts of the dogs

Vivid memories spring to mind The puppies chewing off the daffodils, rolling flat the stocks, the cats finding easy digging in the seed-beds, the mice rooting up the peas, and the hens scattering the polyanthus with those disdainful back-thrusts reserved for all inedible obstructions The rabbits' lolloping breakfasts along the dahlia rows Wire your garden against rabbits, says the diary, shiver at dawn in your pyjamas by the bedroom window with a 22 rifle, we sadly reply

The winds of March bring more than the daffodils They bring the hungry in-lamb ewes down to the home pastures Not even a five-foot dry-stone wall will stop their quest for greenery Prune your plants well back for vigorous growth, says the text, grant that the nibbled stumps will revive, we pray But worse has yet to come, the silly beasts panic into the roses, entangle their fleeces on the thorns, and avulse the entire bushes, roots and all One fat ewe carried for weeks on her rump the proud label "American Pillar" as she trailed our five bob's worth in open mockery

Then the cows come out to grass—our grass and our vegetable garden Cows in the garden can lick bulls in china shops any day They are most unpleasant at both ends. For one thing, they have such an enormous axle-load that all our lettuces are plunged irretrievably into the depths, and we are left disconsolate with a pock-marked wilderness As a final gesture the creatures charge through the raspberry canes, emerging festooned with a tangled wreckage of plants, wire, and bamboo Their owner hopes that they haven't been poisoned by eating our yew trees We favour wing of bat.

What remains of the garden then qualifies to endure the onslaught of footballs, cricket balls, tennis balls, and arrows, lethal not so much per se as by their attendant propensity for getting lost. The grooves of tricycle wheels snake across the lawn, the ends bearing witness to televising dirt-track technique From such memories our green fingers close the diary with foreboding We breathe a silent prayer of thanks that no-one near keeps pigs

* * *

It has been hinted that the new examination technique, recently described in this journal, may have an effect on future graduates and as one who believes in keeping upsides with medical progress, I have already introduced the new doctor-patient technique into my practice Last night, for instance, as my patient hobbled through the surgery door, I snarled "You want—Indicate with a cough your reason for coming here tonight

(*a*) A certificate, tonic, line for glasses and a roll of cotton wool for wee Jeannie
(*b*) To get in out of the rain
(c) A check up going over, sounded, given the once over and a smog mask
(*d*) Nobody else will talk to you"

Silencing his feeble tale I resumed "Have you
(*a*) A cruel pain
(*b*) Something you can t describe but comes often especially at night what with the neighbours and all
(c) Blackouts and coming all over queer
(*d*) A gastric stomach"

We were progressing I continued "Is the pain
(*a*) Round the back, working to the front and you're afraid you'll be taken serious if they meet
(*b*) Something horrible when you bend
(*c*) There because the foreman has a spite at you and put you to heaving coal which is Joe Bloggs's job by rights"

Barring his exit I urged him to answer quickly "true" or "false" to the following questions
" (*a*) You wish you'd stayed at home
(*b*) You feel much better
(*c*) Doctors are grossly underpaid"

I met my patient in the street this morning and he looked at me queerly, but I suppose medical pioneers must expect some setbacks

* * *

Women can be annoying creatures I had just finished re-reading some of the Sherlock Holmes stories and was explaining to my wife that Holmes was based on a well-known doctor I related a few examples from my own experience to illustrate the deductions that might be drawn from fine observation At that point the telephone rang "That'll be Millie," said my wife rising to her feet "I know her ring" Later, when I was patiently inquiring how she could differentiate a telephone bell, our door buzzer sounded "Oh," she said, "that's Jim and he sounds cold" It was Jim, and he was cold I went back to my stories, but somehow they had lost their flavour

* * *

As a conscientious M O H, I have been put in a quandary Shall I or shall I not advise my authority to accept the Ministry's latest suggestion and offer B C G vaccination to school-leavers? If B C G is good for contacts, it may protect children when they leave school for the wider world of exposure On the other hand, I am coöperating in the M R C trial to find out how worth-while mass vaccination of this age group is. To take action now is rather assuming an answer before the result is known I was mulling this problem over in my head yesterday evening while I read my son to sleep with *Through the Looking glass* Later, drowsing myself, B C G and the book began to get mixed up

"Does B C G work?" asked Alice "In some people," the Duchess replied, "but we've arranged a trial to see if it would be useful in school children" "How long will the trial take?" Alice inquired "About three years," answered the Duchess Looking around, Alice noticed crowds and crowds of children carrying cards She asked who they were "Those are school children being given B C G," said the Duchess, "every one of them can have it" "But I thought you were having a trial to see if it would do them any good," said Alice, puzzled "That's quite right, my dear," rejoined the Duchess, "but you see we're having the verdict first and the trial later" "Very interesting," commented Alice, as she went to get her own card

* * *

I am often glad that my duties do not include teaching, but then I always have been the sort of chap whose experiments never quite came off Recently, having been asked, we explained to our three children that human babies, unlike kittens, were born with their eyes open With my luck in these matters I might have suspected that facial œdema would keep our new arrival's eyes closed for four days

* * *

She would none of all your posies ?
Bade you gather her blue roses ?
What a curious neurosis *

Half the world you wandered through
Seeking where such flowers grew ?
Really, what a thing to do

Cases both, quite obviously
You, more fortunate than she,
Made a good recovery

Tell me now did you enlist
The aid of a psychiatrist,
Or spontaneously untwist ?

Letters to the Editor

THE INSULIN MYTH

ir,—An E C T myth appals me! I must disown it d explain that to ignore E C T when discussing insulin impossible, for to repeat it is so often mentioned just another manipulation of the insulin-coma ritual. wanted to make clear that my target was insulin d that such dubious benefits as physical treatments ffer in early schizophrenia could more safely and eaply be obtained by E C T

Its effect is unique in the chronic malignant variety ile relapse and remission within a few days of with awal and re application are familiar with E C T and known with insulin, these points were cited to pport my view and as an indication possibly, of some ecific value To avoid more red herrings across the ll of insulin I must as he will understand leave answered here Dr Hunter's objections (Nov 28) my unscientific attitude to E C T On other points impressive support and that of Dr Gibson (Nov 21) d Dr Jarvie (Dec 5) is most pleasing

As for the extraordinary misconstruction that Dr nford Rees (Nov 28) makes of my article which he kes to be a special plea for E C T based on a series of my n, it will be recalled that these figures mentioned in ssing, in a bare dozen lines were given simply to suggest at the prognosis of early schizophrenia may not be quite black as is often assumed. They gave no support atever for E C T or for any treatment at all Further, these same lines, and as the subject of a whole para aph later I discussed the time factor relating response treatment. Thus Dr Rees accuses me of ignoring

The insulin myth is, I think so well demonstrated by r Mayer Gross's work[1] I am sorry now, that I did t refer to it because of certain details. My reason r this was that at least half his 454 cases at Dumfries ere given adjuvant E C T—a point he does not mention his letter A significant indication was failure to prove after three or four weeks of insulin comas; d, of those with lasting improvement, some 65-70% d had E C T Though this objection to this series oving any worth for insulin is enough the optimal ntrol group he refers to for comparison is also not ove criticism It consisted[2] of voluntary patients the Maudsley in 1935 and it is widely held that luntary patients, with their less florid symptoms and idious onset, have a worse prognosis[3] Dr Mayer ross and his colleagues actually indicated this, and plained that there were difficulties in accommodating ute cases.

The work on conditioned reflexes in rats and on etabolism, from which Dr Mayer Gross draws a tisfying rationale for the use of insulin in a human ental illness with no known metabolic pathology not, I think, satisfying enough to justify a risky eatment otherwise so ill founded.

To question a myth is to invite counterblast as well criticism including of course Dr Sargant's conviction hat truth resides with majorities. I think he misquotes ov 28) a report to the International Congress in aris This report was by Lopez Ibor[4] and not by Seven, at all events it made clear that the value of nsulin might reasonably be doubted and suggested that C.T was preferable to insulin in certain types of schizo phrenia. Dr Sargant's concern for the suffering my rticle may cause will be all the greater if he reaches for a standard textbook[5] and reads the very lukewarm opinion of insulin there, and for the most authoritative book[6] on physical treatments in the language, where he will find little to choose between E C T and insulin in acute schizophrenia This evidence would perhaps encourage Dr Friedmann (Dec 5) to be less certain that it is I who ignore what I dislike and that he has proved the value of insulin while combining it with E C T

Dr Rees and Dr Sargant seem to accuse me of "selecting" my references I made it clear why it was necessary and possible to consider ' only some of the best known careful, and typical reports" This is what I did and, in fact, the missing work for which they plead contains not a single revelation that is absent from the papers I dealt with Moreover, work supporting my case was omitted some of which Dr Mayer Gross kindly pointed out Of the 9 omissions they deplore they have only 3 in common the work of Dr Mayer Gross Freudenberg a paper[7] of whose I mentioned with the brief comment it seemed to require and Finiefs[8] Had I included those papers they name they could readily have found many others, all saying the same thing, with which to reprove me

Though I drew attention to the question of percentages, I see that Dr Rees still reaches conclusions by converting unimpressive small numbers to percentages when he refers to an 8·4% recovery rate with insulin compared to zero with E C T in long-standing schizophrenia[9] Actually this means 2 patients out of 24 nor were they the hospital chronics I talked about, while the social recovery rates in his groups which his letter did not mention were not significantly different This distinction between cure ' and social recovery is always subjective

I make no apology for confining myself to published evidence and ignoring the impressions of clinicians, many of whom have no experience of other approaches to schizophrenia and who use insulin and are often encumbered by many years of it. That they will go on doing so undaunted, does not surprise me for there are so many other intuitions and myths dominating psychiatry

Others matters raised in this correspondence are I think answered in my article but I must comment on Dr Sandison's enthusiasm for his new insulin unit (Nov 21) To take his own figures in whole numbers (which I prefer to percentages) it seems that in a fair sized mental hospital with a small medical staff, perhaps less than ten schizophrenics, in nearly two years, have made some sort of recovery so far brief and *perhaps* attributable to insulin—this at the expense of one treatment death

Can anyone, who is not possessed by furor thera peutica, as Freud called it, and not hypnotised by palaver, syringes, coma and the terror of therapeutic impotence, really believe that the risk and great expenditure are worth it?

RADIOACTIVITY OF TOBACCO AND LUNG CANCER

Sir,—Mr Mulvany's letter of July 25 suggests that natural potassium may have to be added to the list of ' radioactive carcinogens, of which only certain products of the radium and thorium series are so far known to have produced cancer in man[10] The specific radio activity of potassium[11] however, is at least 10^{10} times less than radium and its energy dissipation in tissues 10^{11} times smaller than that of an equal radium con

centration. Other factors will enter into the consideration of a given biological action, but such differences in physical properties suggest that a quantitative assessment of the possible dose to lung tissue should precede any conclusion that the radioactivity of the potassium content of tobacco plays a part in the ætiology of lung cancer.

The accompanying table gives results of testing the tobacco, ash, and condensed smoke of a number of samples of cigarettes in a Geiger counter of the type (M6) used by Mulvany. It will be seen that the counting-rates obtained for the cigarette ash are of the same order as those reported by Mulvany, but in this case the counting-rates have been converted to equivalent weights of potassium by calibrating the counter with potassium salts. Assuming the observed radioactivity to be due to potassium, the table gives the activity in equivalent weights of potassium per cigarette, both as tobacco and as ash. The values for the tobacco and ash are sufficiently alike to suggest that no radioactivity is lost in the process of smoking. This suggestion is corroborated by measurements on a solution in acetone of condensed unfiltered cigarette smoke kindly supplied by Dr Clayson from the smoking machine in the Department of Experimental Pathology and Cancer Research. The conditions of this measurement favoured sensitivity, since the condensate from some 300 cigarettes was contained in the counter. No activity above background, however, could be detected in a long series of counts and the figure of 6 µg "potassium" per cigarette in the condensate is the maximum likely figure assessed from the standard deviation of the measurement.

RADIOACTIVITY OF TOBACCO, ASH, AND SMOKE

Sample	Observed counts per min.		Potassium per cigarette in mg	
	Tobacco	Ash	Tobacco	Ash
	(~2½ cigs.)	(~22 cigs.)		
Smokers' ash	21	207	24 ± 1 8*	26 ± 0 9
Smokers ash (remeasured)	19	189	22 ± 1 3	25 ± 0 9
Smoking machine	23	239	28 ± 2 1	33 ± 1 2
Smoking machine	21	201	25 ± 0 8	28 ± 0 4
Condensate from 300 cigarettes	≯ 0 35		≯ 6 µg	

* Errors given as standard deviations.

It may be concluded, therefore, that such radioactivity as is present in cigarette tobacco remains in the ash and that very little, if any, is transferred to the smoke. If the figure of 6 µg is taken as representing the maximum radioactivity (as potassium) which could appear in the smoke of one cigarette, the highest radiation dose in the lung would be produced if this amount lodged as one particle. Such a particle, however, would be some 300 µ in diameter and would deliver a dose-rate to cells adjacent to it of the order of 2–3 mr per week. This is approximately equal to the dose rate which body tissues receive continually from their average potassium content, local gamma rays, and cosmic rays.[12] For smaller particles the dose rates would be reduced directly as the particle diameter (since the specific radioactivity of the material is constant) and would, therefore, be much less than the natural background dose rate. Where tumours have been known to be due to radioactive materials lodged in the body, the dose rates involved were at least 10,000 times greater than the levels considered here.[13]

The measured activity of the ash per cigarette appears to be rather higher than that of the tobacco, although the differences are hardly outside experimental error. Separate tests showed that the discrepancy was not due to the ash from the cigarette paper. It might be accounted for, however, by the average radioactivity of the air which is usually such that the filtering of a few litres of air by the cigarette could increase the radioactivity of the ash by amounts of the order observed.

INTUSSUSCEPTION

SIR,—I would like to comment on your leading article[1] and the letter by Mr Jones and his colleagues[2] in Newcastle.

Acute intussusception must always be associated with pain, which varies in intensity with the type of intussusception. The pallor of the associated shock may be the only evidence of this at the time when the child is being examined. A tumour can be palpated if examined for carefully enough in every case, although an anæsthetic may be necessary to bring about sufficient relaxation of the abdominal wall to enable the mass to be felt. A bimanual examination with one finger in the rectum may help in making a diagnosis.

The duration of the symptoms before treatment is commenced is admittedly a very important factor, both in estimating the prognosis and in deciding on the best method of treatment. It is not the duration of the trouble, however, that should decide the question of operation, for one occasionally sees patients where an intussusception has been present for several days, but, because of the extreme mobility of the ileocæcal region, in some of these cases, the intussusceptum does not become strangulated and the intussusception may be reduced by hydrostatic pressure. Usually, when an intussusception has been reduced in this way, the fact that complete reduction has occurred can be readily determined—and without the help of radiography. This is due to the fact that in most cases, after reduction, some of the enema passes through the ileocæcal sphincter into the small bowel, and causes an even distension of the abdomen, the degree of distension depending on the time occupied in holding in the bowel the saline or fluid used. On palpating such an abdomen, the fact that there is a considerable quantity of fluid in the small bowel can be readily appreciated, especially because, before the enema is given, the abdomen is usually soft and flaccid. If additional help is required in diagnosing complete reduction, it can be obtained by measuring the circumference of the abdomen before and after the giving of the enema. In those cases where none of the fluid passes into the small bowel, even though the intussusception has been reduced, there will be no distension, and an operation should follow.

Mr Jones and his colleagues say that the majority of cases reported by me as having been reduced by hydrostatic pressure were admitted to hospital within twenty four hours of the onset of the intussusception. This statement, while literally true, implies that the success of reduction by hydrostatic pressure in my series was due to early recognition and treatment. I feel sure that the majority of cases, reported by anyone, anywhere, first come under observation by a surgeon or are admitted to hospital in the first twenty four hours after the onset of the trouble. In 30 of the 100 consecutive cases reported[3] in 1926, the intussusception had been present for twenty four hours or more, and there was no death in any case where the intussusception had been pres[illegible] for less than forty eight hours. Another series[4] of a showed the same proportion admitted to hospital · twenty four hours—namely 15, Several of these : reduced by hydrostatic pressure where the duration e intussusception had been several days, and 1 which been wrongly diagnosed as prolapse of the rectum led quite readily to hydrostatic pressure after seven ʟ.

VISITING CHILDREN IN HOSPITAL

ʀ —I was agreeably surprised to read the annotation his subject in your issue of Nov 28 This the more t was in one of my early writings that attention first drawn to the detailed facts of the hospitalisation ma as described in your opening sentence

ossibly because of the emergencies of war time, my inal monograph [1] attracted no great public attention . I have reason to believe however, that there were r and more pertinent reasons for its non acceptance ook some years before the evidence I had marshalled accepted in psychiatric circles: more resistance eared from one's general medical colleagues some of m even today do not believe in ' the hospitalisation ma. (A prominent member of a regional board nly denied its existence and his remarks received e publicity)

consider, therefore that the *Ministry of Health* were precipitate in their action in attempting to impose y visiting on recalcitrant, or at any rate unbelieving pital staffs. I think a good deal of educational work needed first to bring about what has been called "attitude of acceptance." Otherwise the hostility ly engendered between doting parents and a sceptical sing staff can nullify all the benefits of the visiting elieve that Sir James Spence had somewhat similar eriences when he first brought in the mothers to e their own small babies in his hospital at Newcastle l that by suitable education (of both sides) the iculties were smoothed out

Visiting children in hospital is sure to cause emotional nes at times—in the parent or the child or both—and ess the nursing staff are suitably warned and prepared luding an explanation of why all the upheaval should necessary the outcome in its own way may be every as bad as no visiting at all

eeds. H EDELSTON

SIGN OF ASCITES

Sir,—I would like to draw attention to a hitherto described sign for the detection of free fluid in the itoneal sac, which I have been employing with vantage, since 1948

The patient lies on his back with his legs partly flexed; flank is then flicked or percussed with the firm stroke of a ger while the opposite flank is auscultated with a Bowles al piece and stethoscope. Normally it is customary to r only one sound with each percussion stroke but in the e of ascites, with moderate or large amounts of fluid one en hears a reduplicated sound or even two distinct sounds.

In my experience the double sound is about 6–8 es as common in cases of ascites than with other causes abdominal enlargement. I therefore recommend this a confirmatory diagnostic sign of free fluid in the itoneal sac

CORONARY HEART-DISEASE AND PHYSICAL ACTIVITY OF WORK

SIR —In an earlier letter [1] I indicated that in my opinion physical idleness was a *factor* in the production of degenerative changes in the coronary arteries Since this was published in 1951 there have been two statistical inquiries which have given some support to this theory First, there was the article by Dr Logan [2] who stated that his findings tended to support my theory and a similar view put forward by Dr Stocks.[3] Second, there is the elaborate investigation by Dr Morris and his colleagues described in your issues of Nov 21 and 28

I think it is a pity that Dr Morris and his colleagues took for their inquiry occupations in which the exercise difference is relatively slight I suggested in 1951 that a comparison should be made between scholastic teachers and physical training instructors. There may be statistical difficulties about this, but I still think that it should throw light on the problem

I have been convinced on this matter for some time, as a result of personal observation but I am certain that the only statistical way to convince the doubters—and until the recent articles appeared I have found hardly any support—is to study some special group in which the incidence of coronary artery disease is high and to show that amongst the group there is a special subgroup which has a low incidence and an exercise factor very much higher than that of the main group I have tried to do this myself but without financial and other support it is very difficult nowadays to undertake an inquiry of this kind I thought that the Swiss and Austrian guides would be good subjects for investigation and I made some efforts there but the idea of their dying of coronary-artery disease was treated with such hilarity that the matter could not be pursued

I have for some years been trying to find support from the pathological side by trying to get detailed *personal histories of the type of life which has been led* in cases which I have examined post mortem and by attempting to relate these to the condition of the coronary arteries. Owing to smallness of numbers and the difficulty of getting accurate histories these have not proved conclusive but I am persisting Meanwhile although I cannot be certain of the following statements, I believe that they contain some of the keys to the problem

(1) A few people are so genetically constituted that their coronary arteries are resistant to all adverse factors.

(2) In the remainder the principal factors are of a simple mechanical nature (*a*) the bigger the coronary arteries, the more room there is to have atheromatous plaques without disastrous results (*b*) the faster the blood goes through the coronary arteries the less likely it is that they will develop obstructions in their walls.

(3) Assuming these statements to be correct then the part played by exercise is clear The more you exercise the bigger your coronary arteries the more you exercise the faster the blood flows through them and the more difficult it is for an obstruction to develop on the walls.

(4) I think that the exercise, to be really effective as a protector of the coronary arteries, must be fairly vigorous. The round of golf once a week is not much use

It is probably worth while directing the type of exercise to attempt to maintain a good tone of the abdominal muscles Vigorous contraction of the abdominal muscles must have some effect on the blood flow in the coronary arteries Possibly the success of clamping the aorta during attempts at resuscitation may be related to this factor

I have for some time been considering various exercises with a view to providing the optimum coronary protec tion I think skipping is the best, but people are intolerant of it and, for the ordinary person, dancing of the Scottish country type is the most practicable proposition

EDGAR RENTOUL

DIAGNOSIS OF CARBON-MONOXIDE POISONING

SIR,—The alveolar air of patients with carbon-monoxide poisoning contains a small percentage of CO, according to the equilibrium [1]

$$P_{co} = \frac{HbCO\,(P_{O_2} + 300\,P_{co})}{300}$$

where HbCO is the percentage of carboxyhæmoglobin in the blood and P_{co} and P_{O_2} are the partial pressures of CO and O_2 in the alveolar air For example, 16% HbCO gives 1 part per 10,000 of CO

A method of estimating such traces of CO in air quite simply and accurately has been developed,[2] using palladosulphite in silica gel Air is sucked through tubes containing this material by means of a double aspirator which gives the correct rate of flow A respiratory attachment suitable for obtaining an equilibrium sample of alveolar air has been designed for use with this instrument

This method can be carried out by a semi skilled person in three minutes and appears to offer some advantages in clinical diagnosis compared with spectrometric or titrimetric tests on the patient's blood

Such rough tests as I have made encourage me to think that this method would be effective in diagnosis, but more experience is needed

London N W 3

L T MINCHIN

A CONSULTATION FEE?

SIR,—Would a shilling per consultation, either as an alternative to or as an addition to the shilling per prescription, benefit the community as a whole?

It would in the first place reduce the cost of the health service, which so far has been an embarrassment to both post-war party governments It might discourage some of the "is-your visit really necessary" patients from growing like perennials in general practitioners' waiting rooms It would free these overworked benefactors from attending to numerous minor complaints and so enable them to spend more time on the cases that need their care

Indirect benefits to the community resulting from this would include a greater proportion of the population retaining confidence in their own ability to lead healthy lives, less wear and tear on general practitioners and their wives, and consequently on their families and households, and less prescriptions being asked for and therefore less medicines being prescribed, but greater counter sales at the chemists of first aid dressings, simple household remedies, and dietary accessories The cost of the latter would then be transferred from the nation's to the individual's pocket, while the main costs of diagnosis, of treatment, and of ethical medicines would continue to be borne by the National Health Service

The collection of this second "bob" is a domestic affair, the difficulties of which might be outweighed by the advantages gained A shilling per consultation, as well as a shilling per prescription, would have the serious disadvantage that it would impose further financial burdens on those who depend on medical treatment for their health (and therefore for their happiness), and also on those who, with large families, are the first to feel the pinch caused by increases in the cost of living But a shilling per consultation instead of a shilling per prescription has decided advantages Although this point was the subject of debate in the earlier days of the health service, the years of experience that have since intervened may have thrown different light on the subject It would be interesting to hear the reactions of those whom such a change would concern the most

Woldingham, Surrey

RAYMOND L HANBURY

TRAUMATIC RUPTURE OF THE BILE-DUCTS

SIR,—The comprehensive review of this rare abdominal injury given by Mr Milnes Walker (Nov 7) prompts me to give details of a case at the Royal Hospital, Wolverhampton, 16 months ago According to Mr Milnes Walker's record, it would be the fourth reported since 1938 and the fifty second in the literature

The patient, a young, fit, intelligent man of 21, was injured in a motor cycle accident on June 16, 1952

On admission to hospital he was shocked, and had a compound fracture of the right tibia and fractures of the right patella and right femoral shaft He improved considerably with resuscitation, but 2–3 hours after the accident he began to complain of pain in the upper right abdomen. There was tenderness in the right hypochondrium, and localised rigidity, with normal liver dullness There was no sign of bruising in this area, though it was clear that the right side of his body had received the main force of the impact Catheterisation showed a clear urine It seemed probable that there was injury to one of the organs in the right upper quadrant, probably the liver It was decided, therefore, to explore the abdomen, while the orthopædic surgeon, Mr E A. Freeman, would deal with the fractures at the same time, when the abdominal condition became clear

Laparotomy—There was a small quantity of thin bile-stained fluid in the abdomen and gross œdema and infiltration of bile in the free margin of the lesser omentum and in the region of the common bile duct There was also a small tear of the under surface of the liver which was hardly oozing any blood at all Careful exploration of the bile stained tissues established the following points

(1) At the upper end of the bile stained tissues there was a small opening from which bile trickled, and a probe, passed through this, travelled towards the liver in the right hepatic duct, but attempts to pass it into the cystic duct, which appeared just above the opening, showed that this was torn longitudinally for about $^1/_2$ in

(2) From the posterior lip of the opening a thin strap of bile stained duct lining extended down behind the duodenum, presumably the posterior wall of the common duct

(3) The lower margin of the duct had retracted behind the duodenum

The lesion, therefore, seemed to be an incomplete tear of the common duct extending to the cystic duct, with wide separation of the ends, attenuation of the connecting segment, and considerable collapse of the lumen

These factors made insertion of a tube difficult and stricture formation likely, while the split in the cystic duct excluded cholecystoduodenostomy as an alternative The words of Rutherford Morison on the subject of rupture of the urethra seemed apt "unless your skill can prevent the development of a stricture, you are presiding at the opening of a lifelong tragedy" So Mr R L Benison, consulting surgeon to the hospital, was called in to help to avoid such a tragedy

A rubber T tube, which had to be small enough to enter the collapsed lumen, was inserted with some difficulty, and sutures, which similarly had to be few in number because of the small calibre of the duct, were inserted over the tube Periductal drainage was established and the abdominal wall sutured

The fractures were treated at the same time, and chemotherapy was started

Postoperative Course—There was some distension and sickness during the first 4 days, but a normally coloured stool was passed Jaundice then appeared, the stools became clay-coloured and bile drained freely but in diminishing quantities, for the next 18-19 days.

---

[1] Henderson Y Haggard, H W Noxious Gases. New York, 1943 p 165

[2] Methods for the Detection of Toxic Gases in Industry no 7 Carbon Monoxide H.M Stationery Office, 1950 See Minchin *Iron & Steel Lond.* September 1953. p 425

Cholangiography on the 23rd postoperative day showed most of the dye around the tube but a little had passed into the duodenum. The tube was then gradually clamped over a week, and then kept continuously closed for 3 days with no ill effects except a little local discomfort Further cholangiography showed that the dye passed into the bowel The tube was removed on the 30th day

The patient has been quite well ever since as far as his abdomen is concerned The fractures required prolonged rehabilitation but he is now fit for light work.

The outstanding features of the case were:

(1) The extreme collapse of the common bile-duct rendering anatomical identification in the bile-soaked tissues difficult.

(2) The involvement of the commencement of the cystic duct in the tear, which excluded the use of this duct as an alternative bile channel by means of a cholecystenterostomy

(3) The relatively smooth convalescence without as yet, 10 months later, symptoms of stricture formation, which would usually be expected within a year if this was going to be a troublesome development.

(4) The laceration on the under-surface of the liver which suggests that the force may have been in such a line as to cause the liver to crush or tear the ducts against the vertebræ—a mechanism suggested by Lewis.[1]

My thanks are due to Mr R L. Benison for permission to publish these notes and for his help with the operation.

Wolverhampton, **HENRY B YOUNG**

'CHEMOTHERAPEUTIC AGENT' AND 'ANTIBIOTIC'

SIR,—The purpose of my letter (Oct. 17) was to expose the implications and possible consequences which could arise from Dr Erwin's suggested "basis for 'a more exact liberal definition of chemotherapeutic agent'" (Oct. 24) His more recent use of an 'exact liberal definition' clearly vindicates my point No-one would regard aspirin as an antibiotic simply because 'a sufficient quantity destroys the life of man." All would, without *exception, and unhesitatingly, regard it as a* poison and this quite apart from the fact that 'antibiotics' act, as Professor Waksman (Aug 22) has said "in dilute solution to destroy micro-organisms.

Terms, Sir have connotations—they imply the attributes while denoting the subject If 'chemotherapeutic agent' and antibiotic are as Dr Erwin declares 'terms recently coined, and therefore, still evolving, Dr Erwin can scarce forbear to cheer the sanity and wisdom of Professor Waksman's sober summary 'Proper definitions are available without sacrificing historical perspective, scientific accuracy or current usage, and this should not be left to the whim of individuals who decide to redefine important terms according to their own points of view"

Cape Town. **M GLASS**

CIRCUMCISION

SIR,—In the literature on this subject and in the excellent article by 'Sir Daniel Whiddon" (Aug 15) no mention is made of the fact that it is possible in normal persons, *without* any operation to obtain the same end result—namely an exposed glans The method is as follows:

> During the year or so before puberty the boy is told to retract his foreskin and clean the glans every time he takes a bath. Gradually as puberty approaches, and as the glans becomes hardened the foreskin is kept retracted. This has the effect of *allowing* the glans to grow *through* the foreskin, leaving it behind The end result is a penis indistinguishable from, or superior to the most skilfully circumcised one.

Instruction in this procedure appears to be usually passed from father to son in certain families; few doctors seem to have heard of it There is possibly some risk of balanitis, and the manœuvre should therefore be carried out preferably only under the intelligent supervision of the father

UNCIRCUMCISED

DEXTRAN SULPHATE

SIR,—We should like to answer Dr Berenbaum's comments (Nov 28) on a statement in our paper reporting the therapeutic trial of dextran sulphate One patient (case 8) died from coronary thrombosis while under treatment The statement that staining with toluidine-blue of histological sections taken at necropsy failed to show storage of dextran sulphate is held to be a possible misinterpretation since it is suggested that this method of demonstrating polysaccharides is unreliable unless the material is protein bound or otherwise rendered insoluble

In the first place while we would agree that toluidine blue is an unreliable stain for *neutral* polysaccharides, since in fact *it fails to stain them, in our hands it has been found capable* of demonstrating by the metachromatic reaction concentrations as low as 1-2 μg of *highly sulphated* polysaccharides (such as the material used in our clinical trial)

Secondly during the preliminary biological screening of dextran sulphate we have had available material from animals given dextran sulphates of various molecular sizes Comparisons have been made of tissues prepared by freeze drying techniques, by fixation mounting and staining in alcohol and by the ordinary histological routine after treatment with fixatives containing mercuric salts or with formol saline. It has been our experience that when material was demonstrable by either of the first two methods, it was also demonstrable by the use of the usual techniques in material fixed in watery fixatives.

Experimental evidence from animal studies suggests that while protein binding is essential for the *uptake* of sulphated polysaccharides by the reticulo-endothelial cells it is not essential for the demonstration of these compounds in the cell For example, it has been shown that dextran sulphates of large molecular size form insoluble complexes with the plasma proteins and that these particulate precipitates are cleared from the blood-stream by the phagocytic activity of reticulo endothelial cells Material staining metachromatically with toluidine blue is demonstrable as granules within these cells where it persists for twenty eight days or longer[1] Examination of these granules in freeze-dried material in the ultraviolet light microscope and measurement of the absorption at a wave length of 2800A° gave no indication of the presence of protein in the phagocytosed material if the animal had been allowed to survive longer than four hours after the injection of the dextran sulphate This suggested that the protein moiety of the phagocytosed material was split off and *metabolised quickly by the active proteolytic enzymes* known to be present in reticulo-endothelial cells, leaving the sulphated polysaccharide component to undergo slower katabolism[2] This is in keeping with the findings of Kaplan et al[3] and of Coons et al.[4] who showed that even heterologous and foreign proteins disappear considerably more quickly from reticulo-endothelial cells *than similarly phagocytosed polysaccharides*

On the other hand it has been shown that dextran sulphate of uniformly small molecular size (such as that used in the clinical trial) does not form insoluble complexes with the plasma proteins In our opinion it is for this reason that even in much greater dosage than that used clinically the injection of such material does *not result in the appearance of granular metachromatic* material in the reticulo-endothelial cells of experimental nimals[3] From the results of similar investigation of he material from case 8 (the only human material so ar available), it appeared to us that a similar situation revailed.

It is perhaps worth mentioning that the sulphation of lextran interferes with its staining by the periodic-acid chiff technique (presumably by blockage of glycol roups), so that the technique of Mowry and Millican[5] s, in any case, inapplicable for use in the investigation f these compounds Further investigation of the distri ution of dextran sulphate is now being undertaken by adio autography using dextran sulphate labelled with adioactive sulphur (S^{35})

A J.H.M.O APPOINTMENT

SIR,—The letter from "S.H.M.O" in your issue of)ct 24, which was concerned with the S.H.M.O vis à-vis he consultant, prompts me to describe an experience f mine as a J.H.M.O vis-à-vis the S.H.M.O.

Some time ago I accepted a post as J.H.M.O at a small ıospital The only other doctor at the hospital, the medical uperintendent, was a consultant

When I had been at the hospital some months it came to ny notice that my predecessor as assistant medical officer, man with the same qualifications and experience as myself, ad been a senior registrar, and that he had left when the egional board decided to abolish such a grade at the hospital During his stay there the actual "establishment" had been ne consultant, one senior registrar, and one J.H.M.O., though here had never been a J.H.M.O at the hospital before my rrival. The regional board, when they decided to abolish he senior registrar grading, amended the establishment to e one consultant, one S.H.M.O., and one J.H.M.O My predecessor had been offered the S.H.M.O grading shortly before his departure and had refused it The S.H.M.O post was not advertised before my arrival or during my tenure of the J.H.M.O post

With this information in my head, I told the superintendent that in my view there seemed to be at least a reasonable case for my applying for S.H.M.O status. He agreed that there was in the ordinary sense of the words, but added first, that the regional board would never upgrade a J.H.M.O to S.H.M.O status in a hospital and leave him in that hospital, and second, that if I approached the board on the ground that I was doing the work of one J.H.M.O plus at least that of half a S.H.M.O., they might well see fit to advertise the S.H.M.O vacancy In that case, the superintendent said, someone other than myself might be appointed to the vacant S.H.M.O *post and although there would then still be room on the* establishment for a J.H.M.O., the board might think the hospital could function perfectly well with just two doctors, as heretofore In other words, I should be sacked.

I swallowed hard at this, and in consequence of it and of certain other allied irritations, took steps to obtain a post outside the N.H.S as soon as I could When I announced my imminent departure, the superintendent said that there was really too much work at the hospital for two doctors, and every effort would be made to replace me by a S.H.M.O *and* a J.H.M.O (He also, I should add, expressed great regret that I should be "leaving him"—as he put it) Shortly after I left the hospital, I met a S.H.M.O from the same region He had the same qualifications and experience as myself, and he told me that he had recently been upgraded to S.H.M.O status while remaining in the hospital at which he had previously enjoyed J.H.M.O status. I brought this to the attention of my old superintendent, who maintained a dignified silence

To complete the story soon after my entering the hospital as a J.H.M.O., my superintendent took a month's holiday, leaving me in charge I took his place, while a locum took mine The person who obtained the locum appointment therefore had less responsibility than I during that month At the same time she received (in salary plus emoluments) a rate of remuneration considerably in excess of my own I continued to draw J.H.M.O's salary for the month during which I did a consultant's work. Officially the superintende of another nearby hospital "deputised" for my absent chief in fact he visited the hospital *for just ten minutes* during th month my chief was away—ten fruitless minutes at that

Accordingly, when the superintendent threw cold wa on my idea of applying for S.H.M.O. status, I answered tha I would not deputise for him during any future holiday I had reached this decision, I said, *de facto* because of treatment I was receiving in the matter of my grading *de jure* because it is clearly laid down that J.H.M.O.s ar officers who ... have less responsibility than other hospita officers of non consultant status. I could hardly therefore I said to my superintendent, deputise for a consultant in conscience I should be *going above my station of life* He sighed as a colleague, and submitted as an employee the board At intervals subsequently he hinted that the had come for him to have a holiday On each occasion I agreed —and asked whom he had *in mind* as his temporary deputy I hinted that, as I should presumably be the senior resident medical officer during his absence, I should not feel perfectly confident if his deputy were to visit the hospital at a rate o two and a half minutes a week My superintendent took no holidays.

The following points are noteworthy

1 That, a senior and a junior post being vacant, only the junior post was advertised.

2. That the doctor appointed was expected to assume pa or all of the duties of the vacant senior post as well as hi own.

3 That when he suggested he might at least apply for the senior post, he was threatened with the possibility of losing the junior post

4. That he was told that a certain principle obtained in making appointments to such senior posts only to discove very much later that such a principle did not in fact obtain

5 That a junior doctor was called upon to deputise for a very senior doctor during the latter's holiday, while pure paper arrangements were made for another very senior doctor to deputise and no effort was being made to fill a vacant senior post

EX-J.H.M.O.

BARBITURATES AND ALCOHOL

SIR,—Your annotation of Sept. 12 led me to bring together some observations made during the war, and more recently Fig 1 shows the blood barbiturate levels of a normal person who was on two occasions given amylobarbitone ('Amytal') 0·4 g orally on an empty stomach. Fig 2 shows the blood-barbiturate levels of a proved cirrhotic with an alcoholic history who was given amylobarbitone 0 2 g. orally on an empty stomach Comparison of the two figures shows that while the ratio of the dose to the peak blood level reached is not significantly higher in fig 2 than in fig 1a or b the peak is prolonged in the patient with established liver damage.

In fig 3 the lower curve represents blood galactose levels in a normal person given galactose 40 g. when fasting The test was carried out in the morning after 24 hours' abstention from alcohol The upper curve represents the corresponding levels in the same person the morning after an evening when an excess—but not

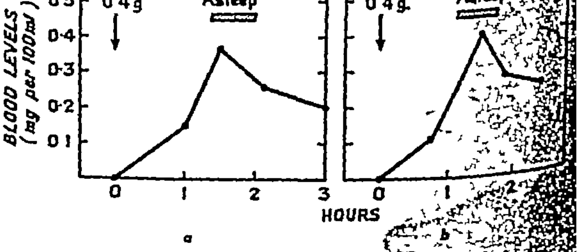

Fig. I.

5 , R. W., Millican, R. C *Amer J Path* 1953, 29 523.

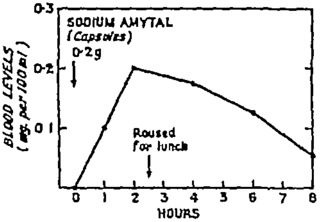

Fig 2.

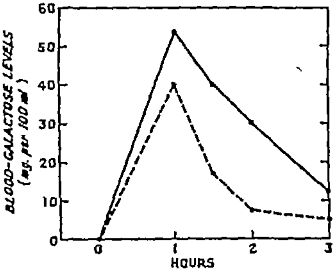

Fig. 3

a vulgar excess—of alcohol had been taken I am doubtful whether taken by itself, the second curve would be regarded as proof of liver dysfunction; but in conjunction with the control curve it strongly suggests that the alcoholic excess had reduced the efficiency (temporarily at any rate) of this person's liver Viewed together the two sets of data help to explain why it may be dangerous to take barbiturates after taking any substantial dose of alcohol or if one's way of life involves regular consumption of spirits

St. George's Hospital Medical School,
London S.W 1
NICHOLAS MARTIN

SURGICAL EMERGENCIES

SIR,—Today when hospital planning and hospital staffing are being widely discussed, and when operating theatres and extensions are being built or are due to be built it seems opportune to discuss the merits of a surgical urgency unit Urgent surgical cases constitute almost half the surgical admissions in the average general hospital, and such a unit would greatly improve their treatment.

These cases coming into hospital throughout the twenty four hours of the day are often kept waiting This may be caused by general list cases blocking the general surgical theatres. Preoperative treatment, transfusions &c., are frequently done under difficulties in a crowded ward. At night, semi-darkness in the ward and a diminished nursing staff accentuate the difficulties.

There is a strong case for having an urgency unit attached to the main general hospital of each group The unit should be controlled by a whole time consultant surgeon (If acute orthopædic surgery is worthy of a whole-time consultant, acute general surgery is too) The consultant should always be available for advice in diagnosis, and treat difficult cases himself The duty registrar and house-surgeon from the duty surgical unit would work under him, treating the casualties and general surgical emergencies

The urgency unit should have 5–10 male and female beds, and its own theatre, sterilising anæsthetic and preparation rooms. Surgical emergencies probably requiring operation would be admitted to the unit. These cases may include all instances of open trauma and abdominal urgencies. The patients would be prepared for operation operated on, and retained in the unit until 9 A.M. the following day when if fit to be moved they would be sent to the appropriate ward whose turn it was to receive urgencies or sent home Very few urgencies are too ill to move in bed in hospital The aftercare of the urgent cases would be the responsibility of the whole time urgency surgeon with the coöperation of the surgeon in charge of the ward to which the patient is sent Head injuries would be admitted to the unit and treated by the surgeon or neurosurgeon as deemed advisable Orthopædic emergencies—i e., compound fractures—would be treated by the orthopædic staff and only admitted to the urgency unit by special arrangement Obviously local arrangements would be necessary to suit individual hospitals.

The urgency unit has the following advantages

1 It enables urgent surgical cases to be prepared for operation or resuscitated with the maximum of convenience and the greatest efficiency and without undue delay All transfusion outfits and preoperative apparatus, &c., can be made instantly available and used in good lighting By concentrating all surgical urgencies in one department there can be economy in instruments, nursing, and technical personnel

2 The general surgical wards can have better and smoother working conditions, and they suffer less disturbance; this is especially valuable during the night

3 The theatres serving surgical wards can be used more fully and with a more regular routine as they are not required for urgencies

The principle of concentrating the treatment of urgent surgical cases would amply repay the public and the National Health Service. Besides the advantages outlined above, the care, foresight, and experience of the established surgeon at present almost limited to the treatment of "list" cases, would be available for the urgent cases which constitute 40–50% of surgical admissions to general hospitals.

Advantage, too should be taken of our resources of adequately trained surgeons (100–150 fifth year surgical senior registrars [1]) to staff these units. Increased opportunity would be available for further research into acute surgical disease, which is still responsible for the premature loss of thousands of lives annually

SOMATOTROPHIC HORMONE AND THE PANCREAS

SIR,—Recent reports have emphasised the possibility that the islets of the pancreas may play a part in the processes of growth. It has been suggested that the peripheral effects on growth of the pituitary somatotrophic hormone (S.T.H.) may be brought about, partly or wholly, by the liberation from the islets of insulin and/or glucagon, produced respectively by the B and A cells [2–5] In this connection, we have been carrying out some morphological studies on the islets of animals under S.T.H. treatment.

In the first experiment, two groups of intact rats, weighing 105 ± 2 g were treated for two to ten days with corticotrophin (A.C.T.H. Armour) or S.T.H. (Armour) the daily dose varying from 1 to 10 mg; nine hours before sacrificing they were given colchicine (40 μg per 100 g body weight). Histological examination of the pancreas stained by Gomori's chromohæmatoxylin phloxyn method showed a large number of atypical mitoses in the islets in both groups but in the S.T.H. treated group the absolute number of mitoses and the proportion of dividing A cells was much higher than in the A.C.T.H. treated group

In another experiment a strain of mice with hereditary pituitary dwarfism, due to recessive anterior pituitary hypoplasia, was used. It was observed that the islets of dwarfs in comparison with those of normal animals of the same strain, were very rich in A cells and consisted of hypotrophic

A and B cells After giving S T H for several weeks, the islets of the dwarf animals increased in number and size and the A and B cells became hypertrophic, whereas the A/B cell ratio was hardly changed at all

Our observations suggest that there is a close relationship between S T H and the pancreatic islets On morphological grounds it seems very probable that this pituitary hormone could stimulate both types of cell in the islets, producing insulin and glucagon But further work is needed to decide whether S T H acts on the islets directly or indirectly and how far the peripheral effects of this hormone can be attributed to stimulation of the islet cells

BACT COLI IN THE CAUSATION OF INFANTILE DIARRHŒA

SIR,—In recent years many reports[1-6] have appeared about the rôle of *Bacterium coli* type O, 111 B, 4 and type O, 55 B, 5 in infantile diarrhœa, and there is already much evidence to incriminate these organisms

In a previous letter,[7] we described the examination of *Bact coli* O, 111 B, 4 and O, 55 B, 5 in the stools of healthy infants and of those suffering from non-epidemic infantile diarrhœa We have also investigated two outbreaks of infantile diarrhœa, associated with *Bact coli* O, 55 B, 5, in a home for infants—that is, in an enclosed environment (apart from new admissions)—here in Nagoya

Fæces from each child at the home were examined weekly, from June 25, 1952, to March 1, 1953, and more frequently when cases of diarrhœa occurred *Bact coli* types O, 111 B, 4 and O, 55 B, 5 were looked for routinely and, from October, 1952, O, 26 B, 6 as well

In July and November, diarrhœa, associated with *Bact coli* O, 55 B, 5, was present in two outbreaks In the first outbreak, 10 out of 20 children were involved This strain was isolated from 7 of them The onset was comparatively mild and signs were very slight In the second outbreak, out of 18 children, 15 were ill and the strain was isolated from 13 of them. This outbreak began very suddenly, there was 1 death, and 3 cases were severe, 6 moderate, and 5 mild Thus, in the two outbreaks, there were 25 cases, of which 20 yielded this strain of *Bact coli*, no other pathogenic organisms were isolated

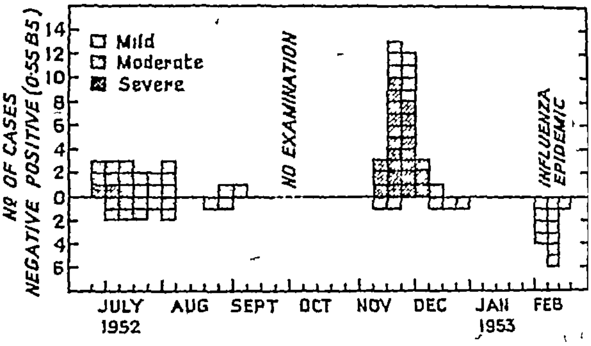
During the period of the outbreaks 5 infants were discharged and 3 were admitted, so that out of the 18 exposed to the second infection, 15 had been exposed to the first If a large number of susceptible infants had entered the home after the end of the first outbreak, this might have accounted for the increased severity of the second attack, but in fact only 3 were admitted, and some of those who were severely ill in the second outbreak had been exposed to the first

The organism was isolated between one and six days before the clinical onset in 6 of the bacteriologically proven cases After clinical signs had subsided and treatment had been stopped, this organism reappeared in 10 out of the 20 cases, but the strain usually disappeared in about a month

In the child who died in the second outbreak, the onset was mild but on the fifth day there was a sudden rise in temperature, accompanied by meteorism, restlessness, and cyanosis and finally by convulsions and death within fourteen hours In this case there were many *Bact coli O, 55 B, 5* in the large intestine and terminal ileum None were isolated from the other organs The intestine was moderately inflamed but the most serious change was fatty degeneration of the liver

In agglutination tests in the other cases there was usually a temporary rise between the second and sixth weeks

Bacteriological investigations of the stomach contents (6 cases), pharyngeal swabs (6), vomit (4), and blood (1) were all negative



Two outbreaks of infantile diarrhœa in a home for infants in Nagoya

During the second outbreak 4 adults (2 doctors, a nurse and a laundress) were found positive for *Bact coli* O, 55 B, 5 2 of them had nausea, abdominal pain, and some diarrhœa.

In the infants' home, two months after the second outbreak, there was an influenza epidemic On this occasion, there were 8 children with diarrhœa Bacteriological examinations were made regularly, but the stools were all negative

Chloramphenicol was given in 7 cases, aureomycin in 3, and streptomycin in 2 We found that all three drugs were effective, but in the 2 cases given streptomycin, there were slight relapses on the sixth and fifteenth days of the illness.

In November, 1952, we tried to obtain these strains in another infants' home in which 60 infants lived Cultural examinations were performed once a week for a month in all the children, but there were no positive results

From these results, it seems clear that these outbreaks of infantile diarrhœa were closely connected with *Bact. coli* O, 55 B, 5 The following facts are interesting

(1) There were 4 children who had diarrhœa with *Bact. coli* O, 55 B, 5 in the first outbreak and who also carried this strain in the second

(2) In the two outbreaks, the severity of the clinical signs and the epidemiological features were different.

INTUSSUSCEPTION IN AN ADULT

SIR,—Teasdale has lately reviewed[1] the literature concerning colo colic intussusception in adults, pointing out that this condition is not as rare as such a review might suggest In 1911 Eliot and Corscaden[2] collected 300 cases, of which only 20 were due to carcinoma, but in Teasdale's series of 242 cases of carcinoma of the colon, seen during the past twelve months, 11 presented with intussusception

I should like to describe a further case

A woman, aged 71, was admitted to hospital as a case of intestinal obstruction on Dec 24, 1950 She had had hæmatemesis 12 years ago, and a partial gastrectomy for duodenal ulcer 6 years ago She had been well until 2 days prior to admission For the past 48 hours she had had severe generalised colicky abdominal pain which had kept her awake at night with one small vomit on the first day of the attack Her bowels had opened regularly until the day of admission. There had been no blood or mucus in the stools

She was a pale and wasted old lady Her tongue was coated and furred There was no distension or tenderness in the abdomen, but a hard sausage shaped mass was felt in the left hypochondrium

At laparotomy on the night of admission, using a right lower paramedian incision, a loose colo colic intussusception was readily reduced from the left hypochondrium. There was no interference with blood supply The cause was a large fungating carcinoma of the cæcum, about 2 in in diameter There were enlarged glands in the mesocolon and mesentery, but no evidence of distant spread Her general condition seemed satisfactory and there was little evidence of dilatation in the small gut, so a right hemicolectomy and end-to-end anastomosis were performed The wound was closed without drainage

---

[1] Teasdale, D H *Brit J Surg* 1953, 41 128
[2] Eliot, E Corscaden J A *Ann Surg* 1911, 53, 169

Section of the tumour showed a tubular columnar-celled carcinoma of the cæcum Sinus catarrh œdema, and congestion but no evidence of secondary carcinoma in lymphatic gland from mesocolon

The patient made a surprisingly good recovery and the postoperative convalescence was uneventful She was discharged as an inpatient on Jan. 11 1951 -

London E.9

R F READ

SUBCLINICAL POLIOMYELITIS INFECTIONS

SIR,—Your leading article of Nov 14 has already been criticised by Dr Bradley (Nov 28) for its misuse of Melnick and Ledinko's [1] interesting study of the development of antibodies in the sera of children during an epidemic in 1948 in Winston-Salem North Carolina There are, however a few points to be added and two misconceptions appearing in your article should be corrected

First it is worth looking at the figures more carefully The epidemic showed an incidence of 62 cases per 100 000 population (highest national figure for this country 20 per 100 000) the ratio of paralytic to non paralytic cases was high (2 : 1) and the *calculated* incidence of actual cases per subclinical infection varied from 6 to 16 per 1000 according to the age group of the children studied (before 1947 the incidence was probably somewhere about 1 per 1000 in this country) By the end of this severe epidemic the percentage of children studied who were immune to each of the three types of virus were

(a) In the upper economic groups

Type I	Type II	Type III
23 (10)	30 (19)	23 (23)

(b) In the lower economic groups

Type I	Type II	Type III
66 (38)	58 (43)	46 (45)

(The numbers in parentheses show the percentage figures before the epidemic.)

Unlike you Sir, I find these figures intensely depressing Winston-Salem had not only had a severe epidemic in 1948 it had also had an epidemic in 1944 and all three types of virus had been represented in one or other epidemic. Yet, even excluding new entrants by birth over half the child population was still susceptible to one or more types of the virus At this rate severe epidemics can go on almost indefinitely—as in fact they have done for the last 50 years in the United States of America.

This brings me to the correction of the first of your two false assumptions. You assume that evidence of subclinical immunisation by poliomyelitis *viruses* is incompatible with evidence that poliomyelitis *disease* runs along narrow streams of the population and that one must therefore choose one set of evidence and reject the other You choose to reject the narrow streams.'

But both sets of evidence are incontrovertible, and no conception of the epidemiology of poliomyelitis which does not accommodate both is admissible. Fortunately they are easily reconciled if one recognises the possibility that different strains of the three viruses may differ—like many other pathogenic organisms—in their virulence. Thus the narrow streams of *disease* are caused by the virulent strains carrying a high rate of clinical disease and the wider *subclinical infection by milder strains* carrying a much lower rate An analogy with *gravis* and *mitis* strains in diphtheria is obvious; both these strains produce a common immunity but they vary markedly in the amount and severity of disease which they cause in the process. Since variations of virulence of strains of poliomyelitis virus are a common laboratory experience, there is nothing revolutionary in suggesting that the same phenomenon is at work during epidemics of poliomyelitis

The severity of any particular epidemic will therefore depend on

(1) the proportion of virulent and non virulent *strains spreading through the population; and*

(2) the population's 'immunological state' (in other words its previous experience of strains of the prevalent types of poliomyelitis virus) To quote two examples In an epidemic among Eskimos in Chesterfield Inlet [2,3] the incidence was as high as 1 in 5 (5%, of the *total population* died and 14% became paralysed) while incidences as low as less than 1 in 1000 have been reported for other population groups.[4-6]

The Eskimos of Chesterfield Inlet were presumably exposed to unusually virulent strains of a type of virus to which they had not previously been exposed (adults were as susceptible as children) Something similar to the Eskimo experience but fortunately not as severe, was seen among British Servicemen in Malta in the winter *of 1942-43* [7] *Their susceptibility to an epidemic affecting* the Maltese children (82% were under 5 years old) contrasted strongly with the immunity of the Maltese adults, who although there was no history of previous *epidemics* in the island were virtually immune Clearly the virulence of strains of a type familiar to the Maltese but not to the British had increased *and with it the ratio of clinical to subclinical infection* Thus exposes your second false assumption—that there is a universal constant ratio for clinical and subclinical infections, which led you to apply the findings in Winston Salem arbitrarily to this country The ratio varies not only from *population to* population but *also for the same* population from year to year

In fact a conception of strains of different virulence within the three different immunogenic types of poliomyelitis viruses makes easy sense of a lot of apparently conflicting data, and yet, since it conforms with general epidemiological principles does not strain the imagination Its immediate practical application is, of course, to the control of the spread of the disease. A strain which has caused one clinical case is for that very reason to be regarded as a dangerous strain which if allowed to spread is likely to show a high incidence of clinical disease (cf the epidemic in Rye last year) Its spread should therefore be prevented by every means we have The mild strains responsible for the subclinical infection we neither could nor would prevent from spreading—in fact, if we could we would help them as much as we would hinder the others, since it is important that they should infect, and so immunise, as many persons as possible before the more virulent strains can infect and not only immunise but also paralyse many of them The present non intervention policy which you would appear to favour results only too often in the race being won by the virulent strains. The result is a steady rise in notification figures all over the world.

In conclusion two recent confirmations of the validity of the 'narrow streams' of disease must be mentioned since your article questions this obvious fact

1 In New York [8] the incidence of clinical cases among household contacts of cases was found to be 40 times higher than among controls. Further 93% of the secondary cases occurred within two weeks of the initial case

2 In the much misquoted epidemic in Denmark at least 28% of the cases studied were found to have a history of contact with another actual case—indirect contacts do not appear to have been studied [9]

The matter is urgent and we cannot afford the luxury of prejudice and ill informed "opinions" Compared with others this country has been fortunate in its experience of poliomyelitis, but we must not abuse our good fortune The experiences of Denmark, Sweden, Canada, and the United States of America, to mention only a few countries, in recent years may well be ours next year unless we initiate deliberately *in advance* measures which will otherwise be *forced upon us—but too late* For "if restrictive control measures in a population are to exert a significant influence they should be applied early in an outbreak to the adults and children who are familial and non familial contacts of the frank case" [10] This was the conclusion of workers studying the distribution of virus and conforms with epidemiological experience not only of poliomyelitis but of many other epidemic diseases

MARGARET AGERHOLM

CORTISONE AND RHEUMATOID ARTHRITIS

SIR,—I should like to give support to the letter by Dr Renshaw (Nov 28) on this subject, for I have found an extract of intestinal mucosa most beneficial in a variety of rheumatic cases seen in general practice over the past six or seven years

Looking over some fifty or sixty cases, including rheumatoid arthritis, osteo-arthritis, spondylitis deformans, gout, and fibrositis, one is impressed by the fact that in only one case was no improvement registered Failure in this case was, I believe, due to the fact that the patient failed to continue the treatment as instructed, she has since had a variety of other treatments with no benefit

The improvement in general health of these patients is most impressive and is followed gradually by diminished pain and increased mobility of the joints

An extract of erepsin, when injected into the tender areas in cases of fibrositis, has a remarkable effect, after an initial stiffness, lasting twenty four to thirty six hours, all pain goes

In practice the treatment is easy to give and control with a minimum of time and trouble, there being no necessity to see patients more frequently than once every four to six weeks

I am quite certain that, if patients can be persuaded to carry out the treatment properly, they will slowly but steadily improve

Sheringham Norfolk.

H C GELDARD

SIR,—I have been in charge of a rheumatism clinic at Warrington Infirmary, in conjunction with the orthopædic clinic, for 27 years Because of the large number of rheumatoid arthritis cases attending, which congested the other work of the physiotherapy department, I endeavoured to relieve the pressure on the department by giving other forms of treatment for this disease These included gold, vaccines, deoxycortone and vitamin C, 'Irgapyrin,' and phenylbutazone (by injection and by mouth)

About eight years ago, after consultation with Dr Arnold Renshaw and on his advice, I decided to give a trial to treatment of a series of cases by intestinal extract, with a balanced protein diet

Given an intelligent and cooperative patient with the requisite amount of patience during the initial few months of this treatment, definite improvement has occurred and has been maintained in well over 100 cases, with less striking improvement in many others Crippled housewives have been able to do their housework and previously disabled industrial workers have returned to modified work

It is important to realise that some considerable time—varying with the individual patient—must elapse before improvement commences In these patients sedatives have been discouraged as much as possible In the few young patients I have treated, the results were very good. The general health in nearly every case was improved and weight increased in debilitated patients

Grappenhall,

BERNARD MURPHY

MARROW BIOPSY

SIR,—It seems to me that a simple and efficient method of performing bone-marrow trephine biopsies is an essential requirement for a hæmatology department. The examination of bone marrow smears, invaluable as it is, does seem, not too infrequently, to need the complementary histological examination of both bone marrow and its adjacent bone The reasons are well known and have been noted by Custer [1] and Block [2] In particular, histological examination is necessary to obtain a reliable guide to the nature and extent of the non-cellular and non-hæmopoietic tissue structures [3] and to the presence of abnormalities such as foci of metastatic neoplasm or granulomata [4-6] Furthermore, the relation of the hæmopoietic to the non hæmopoietic tissues is probably better seen in sections, simple smears sometimes being misleading owing to either blood dilution [1, 2] or greater resistance to suction removal of the more primitive hæmopoietic tissues [7] and sometimes the megakaryocytes.[8] This different resistance to suction removal is particularly important because it results in selected smears which are not representative of the true quantitative and qualitative structure of the marrow [9, 10] This defect may be especially troublesome when dealing with patients who are either taking drugs which depress hæmopoiesis or who have diseases such as erythræmia [11] or chronic myeloid leukæmia [12] in which the hæmopoietic tissues sometimes appear to differentiate into a non hæmopoietic phase

Of course, the examination of bone marrow sections has its drawbacks, one being the difficulty sometimes encountered in identifying the various hæmopoietic cells and another the procedures involved in obtaining the specimen for histological examination Such procedures vary from the simple ones of sectioning fragments of needle aspirated marrow [13] or using needle-like trephines of about no 17 B W G [14, 15] to the more *complicated methods* using ordinary 1 cm diameter trephines [14] or excising $^1/_2$–1 in segments of rib [17] Unfortunately, most of the simpler methods are either inefficient or yield too small a specimen, the more complicated ones seem too drastic for day-to day use in a hæmatology department

Dameshek[15] has described a less drastic plan using a slightly modified Seyfarth's 5 mm. diameter trephine.[16] It seems, therefore, that this size of trephine has a valuable place in hæmatological investigations and it is of interest to note that there is readily available in this country a very suitable trephine for this type of biopsy. This instrument is the trephine for the Blackburn skull traction appliance; it has a T-shaped handle, an adjustable guard allowing a maximum penetration depth of about 8 mm., and an adjustable central pin which aids in rapidly ejecting the excised bone fragment into the fixative. It cuts out a bone fragment of 4 mm. diameter.

With this instrument the biopsy is rapidly performed. Using full aseptic precautions and with the patient under general anæsthesia, the skin over the selected bone is incised for a distance of 2 cm.; the skin is retracted, the periosteum incised, and, if possible, the edges of the periosteum stripped up with a Watson-Cheyne dissector. With its central pin retracted and the guard set at the appropriate depth, the trephine is then rotated into the bone and gently rocked to break the deep trabeculæ and the bone fragment removed within the trephine cavity. An assistant transfers the bone fragment to the fixative. If the bone is unduly sclerotic and does not readily break away, the fragment may be forced out of the bone with a 4 mm. Jenkins gouge. The marrow adjacent to the trephined hole is scraped out with a meibomian-cyst scoop and reserved for smearing. If bleeding is troublesome the bone cavity is filled with a freshly prepared solution of Maw's thrombin, and the periosteum replaced but not sutured; on occasions it may be advantageous to pack the cavity with thrombin-soaked gelatin sponge. On no account should the cavity be packed with surgical gauze. Two sutures are placed in the skin and the wound covered with a dry dressing. Although I have not yet done so, both Custer[14] and Dameshek[15] perform their trephine biopsies under local anæsthesia.

I am much indebted to Mr W. Parke, F.R.C.S., who first suggested to me the use of this trephine. The trephine may be obtained from the London Splint Co. Ltd., 60 Weymouth Street, London, W.1, and the 4 mm. Jenkins gouge and the large meibomian-cyst scoop may be obtained from Messrs. Allen & Hanburys Ltd., London.

London, S.W.3 A. B. HILL.

ALL IN THE DAY'S WORK

SIR,—The Widdicombe discussion (Nov. 14 and 28) on the performance of simple clinical pathology in general practice seems to me, as a hospital pathologist, to be eminently sensible. I do agree that a simple method of hæmoglobin estimation would be best, especially if one observer were to use such a method constantly. One minor criticism refers to the method of syringe sterilisation. Baking is obviously far better than boiling for syringes, as for most joints of meat; but to use an ordinary domestic oven several precautions must be taken. Few are provided with thermometers, and these do not necessarily record the temperature of the part of the oven which might be used for sterilisation. Thermostatic controls are fitted to most of them, but once more they only control the temperature in one part of the oven. Experience has shown me that quite wide variations may take place elsewhere in the oven and it may have quite marked 'hot spots' and 'cold spots.' It is to obviate these, of course, that special design of laboratory ovens is necessary. The same remarks apply to domestic refrigerators, as is well known to anybody who has tried to store blood in one. Note, in addition, that needles used in taking capillary blood must be kept in Lysol.

One final comment is that although it is a bad pathologist who insists that his findings must be 'right,' it is also a bad clinician who insists they must be 'wrong.' The results of laboratory tests are facts which cannot be overlooked any more than such clinical signs as a cardiac murmur or a palpable spleen. In many cases there are anomalous findings, although an ideal picture of what is happening would account for them all. A laboratory result which does not fit the diagnosis has not necessarily been produced by faulty technique. We may not know what it means and it may not help us immediately, but it may well be a clue to further discoveries.

Department of Pathology,
Royal Liverpool Children's Hospital. R. E. REWELL.

Parliament

Air Pollution

IN the House of Commons on Dec. 2 Mr MACMILLAN, Minister of Housing and Local Government, said that the Government had considered the interim report of the Committee on Air Pollution.[1] On Nov. 17, before the report was submitted, doctors were authorised to prescribe masks under the National Health Service for patients suffering from heart or lung disease living or working in an area where smoke-polluted fog is likely to occur. Following the committee's recommendations, the Government had already arranged for the Meteorological Office to issue warnings when serious fog was expected to prevail for at least 24 hours in areas of normally high pollution. These fog warnings would be accompanied by advice to the public about the ways in which they could help to reduce smog and its ill effects. The Government were studying further steps which might be taken to ensure application of these measures and make them more effective while awaiting the next report of the Beaver Committee.

QUESTION TIME

Use of Agene in Flour

Replying in the House of Lords to Lord HANKEY, Viscount WOOLTON, Chancellor of the Duchy of Lancaster, said that although good progress had been made, the investigators into the use of agene in flour for human or animal consumption were not yet complete. It was hoped, however, that it would be possible to make a statement on the subject within the next three months or so.

B C G Inoculation of School-leavers

Mr S. P. VIANT asked the Minister of Health whether any means had been devised to follow the medical history of school-leavers who underwent B.C.G. inoculation; and how, should such persons subsequently develop tuberculosis, can the fact that they had been inoculated be ascertained in the case of those who left the area in which the inoculations were performed.—Mr IAIN MACLEOD replied: Local health authorities have already been advised to keep records of the vaccination of older school-children together with information of their follow-up. These records should enable the date of a particular inoculation to be ascertained later by communication between the authorities concerned.

Tuberculosis Notifications

In answer to a question Mr MACLEOD stated that the tuberculosis notifications for England and Wales for 1952 numbered 48,093 (respiratory 41,904; other forms 6189). He regretted that these figures had been inadvertently omitted from table 37 of the *Annual Abstract of Statistics*.

Medical Grading of National Service Recruits

Replying to a question Mr HAROLD WATKINSON, parliamentary secretary to the Ministry of Labour and National Service, stated that since 1948 the numbers of men called up for National Service and the numbers rejected on medical grounds were as follows:

Year	*Called up*	*Rejected on medical grounds*
1948	150 900	27 750
1949	166 000	36 370
1950	174,200	47,314
1951	168 651	43 866
1952	170,384	47,899

Sexual Offences

Replying to a question Sir DAVID MAXWELL FYFE, the Home Secretary, said that in 1938 the number of unnatural offences known to the police in England and Wales was 134; the number of attempts to commit unnatural offences (including indecent assaults on male persons and cases of importuning for immoral purposes dealt with on indictment) was 822, and the number of offences of gross indecency was 320 The corresponding figures for 1952 were 670, 3087, and 1686

---

[14] (see earlier page)

[15] Dameshek, W. Amer. J. med. Sci. 1935, 190, 617.

[16] Seyfarth, C. Dtsch. med. Wschr. 1923, 49, 180.

[1] The report is summarised on p. 1257.

Sir Robert Boothby Is the Home Secretary satisfied that the law relating to sexual offences is really effective and workable? Is he satisfied with the present institutional treatment of sexual offenders, and does he not think that further research into the problem, perhaps beyond purely departmental research, is urgently required? Sir David Maxwell Fyfe One element in dealing with this matter is the protective element in punishment, because homosexuals in general are exhibitionists and proselytisers, and are a danger to others, especially the young, and so long as I am Home Secretary I shall give no countenance to the view that they should not be prevented from being such a danger As regards treatment, I should like to assure the House that we are very much alive to the problem in our prisons today Arrangements are made for medical attention, especially of a psychiatric kind But the difficulty in these cases is that for treatment to be successful there must be coöperation, and in many cases coöperation is refused

The third point that must always be borne in mind is that apart from the true invert, there are homosexuals who use that instead of ordinary sexual intercourse, the male prostitutes who come up on these importuning cases, and the sensationalists who would try any form of excitement and indulgence These three types of cases, apart from the male invert, can be dealt with, and are being dealt with, by our prison system I am trying to study and give my careful attention to the whole problem, but it would be wrong not to stress these points

Mrs Braddock Will the Home Secretary consider carefully the medical aspect, because many magistrates who understand the situation are reluctant to give terms of imprisonment in these cases because of overcrowding in prisons where men are put two or three in a cell? It is considered that sending them to prison accentuates the trouble rather than cures it Sir David Maxwell Fyfe Unfortunately, owing to the shortage of space, there are about 5000 people who are three in a cell This matter has been carefully examined, and I believe that the chances of increasing homosexual inclinations from that cause have been greatly exaggerated Although, of course, homosexuality exists in prisons—as Sir Alexander Paterson said, you cannot help it in a "monastery of men unwilling to be monks"—I think the effect has been exaggerated We have not been able to find any evidence of much increase of inclination

Examination of Mentally Deficient Children

Mr A J Irvine asked the Home Secretary whether, in cases where a child was examined under the procedure referred to in section 9 of the Mental Deficiency Act, 1913, it was the practice of his department to permit, if the child's parents desired it and at their own expense an examination of the child by an independent medical expert of the parent's choice and to give consideration to the report following such examination —Sir David Maxwell Fyfe replied Section 9 of the Mental Deficiency Act, 1913, empowers me to order the transfer to a suitable institution, or the placing under guardianship, of a child detained in an approved school or, in certain circumstances, in a remand home, if I am satisfied from the certificates of two qualified medical practitioners that the child is a defective Such certificates are considered most carefully, in the light of the medical advice available to the Home Office, before any action is taken on them. I am prepared to give favourable consideration to requests by parents for an examination by a doctor of their own choice where there is reason to think that the further opinion would be of value in the few cases where such requests have been made hitherto it has not been considered that a further examination would serve any useful purpose

Medical and Dental Recruitment

Mr Percy Morris asked the Minister of Health how far he was satisfied with the rate of recruitment to the medical and dental professions, and how far he anticipated that the needs of local government social services would be adequately met from such sources during the next three years —Miss P Hornsby Smith replied Recruitment in the medical and dental profession is through entry into university medical and dental schools—which are outside the Minister of Health's control He has no grounds for thinking that the number of doctors qualifying will be insufficient to provide for recruitment to local government or other services but fears that the shortage of dentists will not be overcome in the period mentioned

Fluoridation of Water-supplies

Replying to a question Mr Macleod said that the Government had decided to accept the recommendations of the report of the United Kingdom Mission which studied the fluoridation of domestic water supplies in North America as a means of controlling dental caries In conjunction with the Minister of Housing and Local Government, who was responsible for public water supplies in England and Wales, the Secretary of State for Scotland and he proposed to arrange for studies to be made in some selected communities of the various aspects of the fluoridation of water supplies before considering whether fluoridation should be generally adopted in this country An approach would be made to certain local authorities to invite their coöperation in making these studies

Woodberry Down Health Centre

Colonel Malcolm Stoddart Scott asked the Minister what information he had about the extent to which the Woodberry Down Health Centre, Stoke Newington, was being used, and what accommodation at the clinic was still unused Miss Hornsby Smith replied The whole of the centre is in use except two dental laboratories, one dental surgery, a medical store, a clinical side room, and the doctor's night-duty accommodation

---

Obituary

THOMAS YULE FINLAY

M.D Edin., F R C.P E

Dr T Y Finlay died on Nov 28, in Edinburgh where he had spent his whole professional life and where he was the first maternity and child-welfare medical officer

Born in Paris in 1882 of Scottish parents, his early days were spent there, but when his family returned to Edinburgh he became a pupil at the Royal High School and then proceeded to the university where he graduated M.B in 1907, obtaining the M D with high commendation in 1912 His brother-in-law, Dr Gaston Variot, of Paris, was a pioneer in the infant-welfare movement, and Finlay early in his career showed a keen interest in child care This interest was also encouraged by his intimate association during his hospital residencies with the late J W Ballantyne and John Thomson Finlay always acknowledged the great debt he owed to these two distinguished men

In 1913, when he was medical superintendent of one of the large poorhouses in Edinburgh, he introduced new methods of treatment, supervision, and record-keeping of the children resident there which attracted the favourable attention of the Local Government Board for Scotland In 1919 he was the natural choice of Edinburgh Corporation as medical officer in charge of the newly formed maternity and child-welfare section of the public-health department He was blessed with the gift of bringing happily together voluntary and official agencies for the care of mothers and young children, and the section of which he was head expanded its functions steadily and achieved fruitful results

In 1922 he took the M.R C P E, and the same year he became an assistant physician at the Royal Hospital for Sick Children He was also appointed senior assistant physician to the reorganised children's unit of the municipal hospitals' service He was a lecturer and examiner on diseases of children and child hygiene at the university and at many other teaching bodies in the city, and he was early in the field in the training of health visitors He became F R.C P E in 1927 He was a member of many medical and pædiatric societies. An honour which he greatly valued was that of honorary membership of the British Pædiatric Society, of which he was an original member When he retired under the age-limit in 1947 his faithful services to the city were publicly acknowledged In his retirement he flung himself wholeheartedly into the work of several of the voluntary organisations with which he had been closely associated during his official career

He is survived by his wife, daughter, and two sons.

Notes and News

LIBRARY OF THE ROYAL COLLEGE OF PHYSICIANS

The first published catalogue of the library of the Royal College of Physicians of London which appeared in 1660, contained 1278 titles Today the college has 40 000 printed books, 600 manuscripts, a small collection of letters and the H. M Barlow collection of bookplates from medical institutions. The Harveian Librarian has lately issued a short introductory note which sets out some of the library's story

The original collection was based on the library of Thomas Linacre, who founded the college in 1518 William Harvey was another benefactor who gave not only books but a museum in which to house them A great deal was lost in the Great Fire of 1666 but the bequest of the Marquis of Dorchester's library in 1688 did much to offset this catastrophe The most notable gift of recent years has been Dr Lloyd Roberts's library received in 1921—an addition of considerable value to medical historians. The library is now very well provided with biographies and has over 5000 engraved portraits and photographs of medical men But its shelves have never been restricted solely to medical works: its treasures include the Wilton Psalter (c 1250) Caxton's *Recuyell* (c. 1475), and the only known copy of the first book on dancing (Paris c. 1488)

MEDICAL WAR RELIEF FUND

The committee of this fund, at a meeting in London on Nov 17 approved a report prepared by the distribution subcommittee on the year 1952–53 The report showed that 41 awards amounting to £2000 had been made. The largest gift (£500) was to the Australian War Relief Fund which was in need of help to deal with urgent cases. As in previous years, educational grants were in the majority and 15 widows were helped with the payment of school or university fees or the purchase of school outfits. At Aug 31 the balance remaining in the fund was just over £13,000

THE ST JOHN AMBULANCE AIRBORNE

The St John Ambulance Brigade can now provide attendants for patients travelling by British European Airways and it is hoped to extend this service to other air lines in due course The members of the service have passed airworthiness tests and are qualified in air duties and emergency midwifery as well as in first aid and nursing The service is voluntary but patients will be expected to pay the attendant's fare and reasonable out-of pocket expenses. Further particulars may be had from brigade headquarters, 8, Grosvenor Crescent, London S W 1

LINEAR ACCELERATOR AT ST BARTHOLOMEW'S HOSPITAL

St. Bartholomew's Hospital London, is to have a linear accelerator producing X rays by bombardment of platinum foil with electrons of a potential of 15 million volts. This will be the largest apparatus of its sort in existence for medical purposes A similar machine is being built for Harwell for physical research. At the hospital the apparatus will be used for the treatment of cancer the development of new methods of treatment, and fundamental research on the effects of high energy on the human body The cost is being met by the governors from their endowed funds and King Edward's Hospital Fund for London have promised a contribution.

STRESS AND ATHEROSCLEROSIS

To test a clinical impression, the frequency of atherosclerosis and some other degenerative conditions, as the cause of death, was compared in two Jewish groups in Denmark.[1] The one group, long established in the country and affluent but dwindling in numbers was believed to have led a more sheltered life and consumed a diet richer in cholesterol than the second group composed of immigrants from Russia who had had a hard struggle to establish themselves. So far as stress was concerned, it could not be maintained that the men of the two groups differed greatly, though their different economic status exposed them to superficially different physical and emotional demands. Between the women of the two groups however there were conspicuous differences in respect of such presumptive stresses as marriage childbirth and domestic work. Corresponding differences were not found in the total proportion of deaths from atherosclerosis but the age of death from this cause was earlier in the immigrant group of women The authors do not carry out any statistical analysis beyond the calculation of percentages, and it is difficult to draw any firm conclusions from their findings. The two populations studied were small and there were many possible sources of error nevertheless the report is an interesting essay in social medicine.

W V S HOSTELS FOR MOTHERS AND CHILDREN

The hostel which was opened by the Women's Voluntary Services in 1945 at Clapham, to help mothers and babies suffering hardship as a result of the war has now been moved to Streatham. It is intended to help women who have no home of their own and who have nowhere to go before or after discharge from hospital A resident matron and two assistants teach the mothers to look after their babies and give instruction on the principles of feeding and babies laundering and so forth.

The W V.S also run a short-stay home at Whitstable where children can go whose mothers have been taken into hospital or who might break down if they did not have a rest away from home At Aldeburgh they run a recuperative home where children may stay for a month convalescing from chest diseases. Further particulars may be had from the W V.S 41 Tothill Street, London S W 1

NEW FILMSTRIPS

Four filmstrips recently produced for the World Health Organisation set out to inform the public of some of its activities.[1] *Penicillin*, which is perhaps the best of them, deals mainly with the way in which it is being used to combat endemic syphilis bejel, yaws, and pinta. *The Fight against Tuberculosis* shows some of the aetiological factors and gives an account of the work carried out at the Tuberculosis Centre Istanbul *Malaria* uses an anti malaria campaign in Thailand as an illustration of what preventive measures can do *For Babies Born too Soon* shows developments in the care of premature infants. In the first three the over-all picture is fairly well balanced, but this last one seems to emphasise unduly the work of a single clinic in Paris A fifth filmstrip[2] has been prepared to teach teen-agers and young wives the methods and value of breast-feeding The value of all these filmstrips will depend largely on the ability of the lecturer who uses them. None of them make any serious attempt to exploit the visual medium, and few of the pictures are more than a background illustration.

University of Cambridge

On Nov 28 the degree of M.D was conferred on M G Thorne and J K. Wagstaff.

University of London

The degrees of M B B.S, have been awarded to D D J Rees.

University of Manchester

The following have passed the final examination for the degrees of M B, CH B

Sheila Berry J K Bleasdale, Cyril Booth Margaret A Broughton J W Chamberlain, G H. H. Dwyer Pauline R. Dyckhoff Gerald Gold Lawrence Goldie Aubrey Greenbaum Mabel L. Royal College of Physicians of London

Dr J T Ingram will deliver the Watson Smith lecture on Monday, Jan 11, at 5 P.M, at the college, Pall Mall East, S W 1, on the Significance and Management of Psoriasis.

Royal College of Surgeons of England

On Monday, Dec 14, at 5 P.M, at the college, Lincoln's Inn Fields, London, W C 2, Prof Geoffrey Hadfield will deliver the Kettle lecture He will speak on the Dormant Cancer Cell

Industrial Injuries Advisory Council

Prof R E Lane, F R C.P, has been reappointed to this council, and Mr A Miller, F R.C.S E, and Dr L 'G Norman have been appointed

Collecting Tissue Grafts

The French Académie de Médecine (*Times*, Dec 4) is seeking to introduce legislation to permit surgeons to take tissue grafts from the bodies of young people killed in road accidents.

Chartered Society of "Queen Square"

The council of this society will shortly hold an election to fill vacant pensions (£20 per annum) which are available for people with incurable nervous diseases Forms of application and further particulars may be had from the secretary of the society, National Hospital, Queen Square, London, W C 1

Heberden Society's Dinner

Speaking at the Royal College of Surgeons on Dec 4, Sir David Maxwell Fyfe said that as Home Secretary he was interested to find that Heberden had been one of the first debunkers of the "super-poisoner" For thousands of years people had feared the master poisoner, who made the flower kill through its perfume or the ring through its touch, but Heberden had let in the cold air of science, describing these stories as the idle results of ignorance and superstition Heberden had also been well versed in the classics—before the days when the Greek dramatists had become no more than a quarry for Viennese psychologists seeking names for their complexes This year the Heberden oration had been given by Sir Russell Brain, and the Heberden round had been conducted in Lancashire by Dr J H Kellgren, who had since been appointed professor at Manchester Paying tribute to Heberden as a physician of the past, Sir David also paid tribute to a physician of the present—one, he said, who does not stand austerely on a pinnacle of fame but gives his friendship to an infinite variety of people who don't deserve it, and thereby enriches their lives. Lord Horder, in reply, somewhat reluctantly forgave the Home Secretary for these personal remarks after all, Sir David might not have a chance of making them again—he might not be asked again. Welcoming Prof R E Tunbridge as his successor in the presidency, he said that the society had had a successful year With a membership limited to 100, it had a waiting list of men and women well versed in what he must now regretfully call rheumatology Comparing the position of the subject now with its position twenty years ago, it was evident that Cinderella had now been found by the Prince and taken to the dance The three major advances of the last two decades came from recognising (1) that chronic rheumatism was a hotchpotch which needed separation both technically and administratively, (2) that it was not a local or a focal disease but an expression of the patient's fitness or otherwise and (3) that the nervous system, in its relation to the vertebral column, played an important part in many cases of rheumatism This had been well illustrated in the Heberden oration on Spondylitis delivered by Sir Russell Brain, to whom Lord Horder proceeded to present the Heberden medal Dr W S C Copeman proposed The Guests in varying blends of respect and disrespect, and drew an equally light hearted response from Miss Patricia Hornsby Smith, parliamentary secretary to the Ministry of Health

---

CORRIGENDUM *The Anæsthetist's Responsibility*—In the third paragraph of this leading article (Nov 21, p 1080) the third sentence should read "Perhaps the most helpful measure is the administration by inhalation of a broncho dilator such as isoprenaline, and postural drainage with vibratory and clapping percussion of the chest" In the fifth paragraph the last word in the sixth line should be "synchronous"

Mr Patrick Clarkson is to be the guest speaker at the annual meeting in January in Chicago and Cleveland of the American Society Hand Surgery

Diary of the Week

DEC 13 TO 19

Monday, 14th

Royal College of Surgeons Lincoln's Inn Fields W C 2
5 P.M *Prof Geoffrey Hadfield The Dormant Cancer Cell* (Kettle lecture)
Postgraduate Medical School of London, Ducane Road, W 12
4 P.M Dr Brian Ackner Emotional Factors in Treatment Response
University College, Gower Street, W C 1
4 45 P.M Mr H Gutfreund, PH D Molecular Forces in Protein Solutions (Last of two lectures)
Royal Eye Hospital St George's Circus, S E 1
5 15 P.M Dr T H Whittington Accommodation Clinically Considered, Cycloplegics, Retinoscopy
Medical Society of London, 11 Chandos Street, W 1
8 30 P.M Mr John Bunyan, L.D.S Application of the Microscope to Medicine Dr George Lumb Pathology and Spread of Cancer of Breast. Dr W H. McMenemey Degenerative Changes in Brain Following Stoppage of Heart During Surgical Operation

Tuesday, 15th

Royal College of Surgeons
3 45 P.M Mr C le Q Darcel Comparative Pathology of Leukotic Conditions in Man and Fowl (Imperial Cancer Research Fund lecture)
5 P.M Mr D Innes Williams Chronically Dilated Ureter (Hunterian lecture)
Institute of Dermatology, St. John's Hospital, Lisle Street W C 2
5 30 P.M Dr F Ray Bettley Atopy
West End Hospital for Nervous Diseases, 40, Marylebone Lane, W 1
5 30 P.M Dr T Rowland Hill Neurological demonstration.

Wednesday, 16th

Royal Eye Hospital
5 30 P.M Mr H B Jacobs Relation of Nasal and Ocular Diseases.
Institute of Dermatology
5 30 P.M Dr J O Oliver Laboratory Diagnosis of Syphilis.
Institute of Urology 10, Henrietta Street, W C 2
5 P.M Dr A H Harkness Non gonococcal Urethritis.
Eugenics Society
5 30 P.M (Burlington House Piccadilly, W 1) Dr Hermann Lehmann *Distribution of Sickle-cell Trait in Africans* and Indian Aboriginals

Thursday, 17th

Royal College of Surgeons
3 45 P.M Dr J Stretton Young Benign Mammary Epithelial Hyperplasia. (Erasmus Wilson demonstration.)
Institute of Laryngology and Otology, 330, Gray's Inn Road, W C 1
5 P.M. Prof. F C Ormerod Anatomy of Paranasal Sinuses.
Harveian Society of London 11, Chandos Street, W 1
8 15 P.M Prof Alan Moncrieff Marasmus Dr R E Bonham Carter Congenital Heart Disease Dr B Schlesinger Infantile Diarrhœa

Friday, 18th

Royal Society of Medicine, 1, Wimpole Street, W 1
4 30 P.M *Section of Epidemiology* Dr P L McKinlay Cancer in Scotland
Royal Eye Hospital
5 30 P.M Prof. C A. Keele Local Anæsthetics in Ophthalmology
Institute of Dermatology
5 30 P.M Dr Bettley Clinical demonstration

ASSISTANT SURGEON WESTERN INFIRMARY, GLASGOW

In all the field of medical practice there can be few conditions more perplexing to the physician and more troublesome to the patient than that recurring chronic ulceration of the lower third of the leg variously termed varicose ulcer non specific ulcer, or gravitational ulcer Such ulcers are characterised by the site of their occurrence—the gaiter area—and by the fact that they usually heal with rest in bed but tend to recur when the sufferer becomes ambulant There are great variations in size and severity of symptoms some of these ulcers are painful, some are not some are associated with obvious and gross varicose veins some are not; some are apparently related to previous deep venous thrombosis and some are not. The incidence of the condition is difficult to assess

The usual sequence of events in the development of gravitational ulcer is venous stasis → pigmentation of skin → induration → œdema → subcutaneous fibrosis → diminished local vascularity → minor trauma → indolent ulcer The induration which precedes the ulceration varies considerably in extent, from a patch on the anteromedial aspect of the leg to an encircling gaiter In the first type the patch of induration and later the ulcer often appears to sit astride a prominent superficial varicose vein—the feeder vein of Paré—this is the typical varicose ulcer of Brodie (1846) In the second type the ulcer may be single or multiple and at the same site, but there are often no evident associated varicose veins nor any history of such In some of these cases there is a clear history of antecedent deep vein thrombosis or superficial phlebitis and this type has been termed the postphlebitic ulcer by Homans (1916) and others

General Considerations

It is generally accepted that gravitational ulcer is due to venous stasis, but the ulcer rarely bleeds and is always set in a zone of increased subcutaneous fibrosis. The ulcer is usually in the lower third of the leg and on the anteromedial aspect, where Bellocq (1925) has shown that the arterial plexus of the skin has a very wide mesh and the vessels are of small calibre If the stasis is alleviated by rest or support in most cases the œdema resolves and the ulcer heals more or less soundly

Local stasis may be due to either arterial or venous insufficiency Arterial insufficiency alone may rarely lead to ulceration indistinguishable from gravitational ulceration.

The factors which influence the venous return from the lower limb are as follows

(1) Vis a tergo—the arterial inflow
(2) The pump action of the limb musculature which, to be most effective demands
(3) Soft compressible veins, and
(4) Competent vein valves.
(5) Heart action producing a suction effect in the cavity veins.

Gravity and obesity militate against these factors to various extents.

In the normal limb venous blood flow is always centripetal no matter what is the attitude or the activity of the patient, and this is ensured by valve competence Any factor which destroys or impairs valvular competence allows venous reflux and stasis.

Hæmodynamics

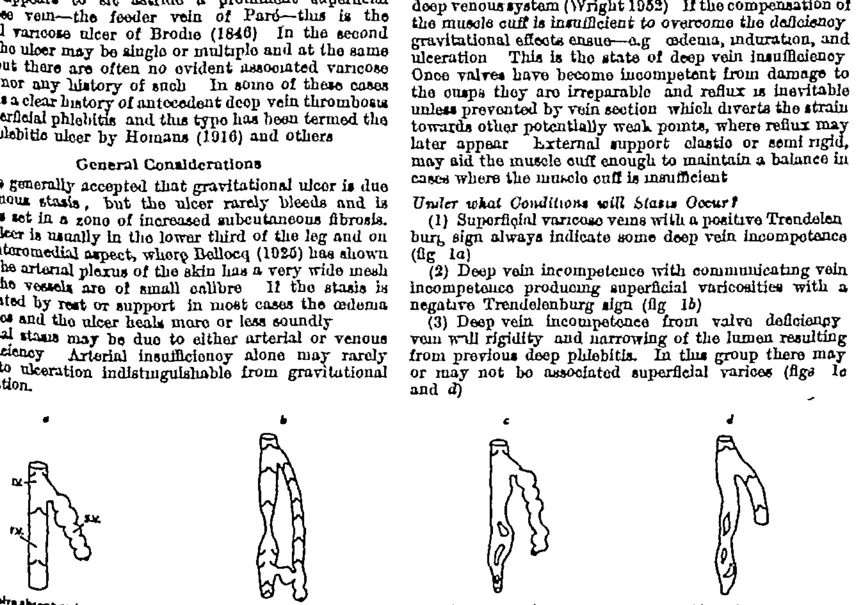
To obtain a normal deep venous return the deep vein valves must be competent, and the vein wall must be soft and elastic and surrounded by skeletal muscles capable of exercising a massaging pump action. Anything which interferes with valve action or pump action may produce stasis. Valve incompetence permits venous reflux, which will throw a strain on successively lower valves and ultimately on the valves of the communicating veins If these valves in turn become incompetent the strain will be transferred to the superficial system, and this is, I believe, the essential cause of most varicosities of the superficial veins—i.e. the primary defect is in the deep venous system (Wright 1952) If the compensation of *the muscle cuff is insufficient to overcome the deficiency* gravitational effects ensue—e.g œdema, induration, and ulceration This is the state of deep vein insufficiency Once valves have become incompetent from damage to the cusps they are irreparable and reflux is inevitable unless prevented by vein section which diverts the strain towards other potentially weak points, where reflux may later appear External support elastic or semi rigid, may aid the muscle cuff enough to maintain a balance in cases where the muscle cuff is insufficient

Under what Conditions will Stasis Occur?

(1) Superficial varicose veins with a positive Trendelenburg sign always indicate some deep vein incompetence (fig 1*a*)

(2) Deep vein incompetence with communicating vein incompetence producing superficial varicosities with a negative Trendelenburg sign (fig 1*b*)

(3) Deep vein incompetence from valve deficiency vein wall rigidity and narrowing of the lumen resulting from previous deep phlebitis. In this group there may or may not be associated superficial varices (figs 1*c* and *d*)



a:
valve absent or incompetent.
enous valve incompetent.
insufficiency localised.
ficial insufficiency extensive.
rficial varices.
Trendelenburg positive.
Ulcer uncommon.

b:
Normal iliac vein.
Normal upper deep vein.
Localised deep thrombosis with resultant
Localised deep insufficiency
Localised superficial varices.
Trendelenburg negative.
Ulcer uncommon.

c:
Iliac valve absent or incompetent.
Saphenous valve incompetent.
Deep-vein thrombosis with resultant
Extensive deep insufficiency
Extensive superficial varices.
Trendelenburg positive.
Ulcer common.

d:
Normal iliac vein.
Normal saphenous vein.
Deep femoral thrombosis with resultant
Extensive deep insufficiency
No superficial varices.
Trendelenburg negative.
Ulcer common.

Fig 1—State of venous valves in various conditions in which gravitational ulcer may develop: F V., femoral vein; I.V iliac vein; S.V., internal saphenous vein.

Gay (1868), in post-mortem dissection of ten legs the seat of gravitational ulcer, found the deep veins partially obstructed by thrombus in six cases and dilated and tortuous in three He also noted that "after deep thrombosis the channels are to a great extent restored by contraction of the clot and eventually organic combination with the vein wall"—a simple fact often lost sight of to this day

It seems clear that the deep veins are the most important element in the venous system of the leg, and that in gravitational ulcer one must treat the deep-vein insufficiency while accepting that some degree of underlying deep-vein valve incompetence is permanent

Demonstration of Reflux

Demonstration of reflux into the superficial veins is usually easy The Trendelenburg (1881) test is positive in most cases of varicose veins when first seen (Wright 1950) Further, in almost all such cases a cough impulse can be felt in the saphenous vein, indicating that increases of intra abdominal pressure are being transmitted to the superficial veins of the limb and, therefore, that at least the iliac valve and first saphenous valve must be incompetent

The regularity with which varicosities of the internal saphenous vein will recur, from above, after high ligation operations, unless the internal saphenous vein is tied flush with the femoral vein above all tributaries, is striking (Wright 1949) Abdominal reflux into the internal saphenous vein can only be prevented by ligation at the sapheno-femoral junction If superficial varices recur after adequate high ligation, reflux through incompetent communicating veins will be demonstrable and can be prevented by division of such communicating veins This, again, confirms that the primary fault is in the deep veins When superficial varices recur after treatment they are recanalised from above downwards, and this is so after inadequate ligation and after sclerosing injection and also after spontaneous thrombosis. All these facts emphasise that the primary defect is in the deep veins and that superficial varices are a reflection of deep-vein incompetence

Prevention of Reflux

Reflux into the main superficial veins can be prevented by division of the veins surgically at their points of entry into the deep veins (Homans 1916)—to be effective this must be done exactly at these points (Wright 1949)—and by section of incompetent communicating veins Stasis in the superficial plexus can thereafter be reduced by obliterating these veins by either sclerosant injection or excision

Sclerosant Injection

Sclerosing fluid injected with the intention of producing a chemical phlebitis carries the danger of damage to the deep veins and communicating veins and their valves Experience shows this to be a theoretical risk, provided the sclerosant is viscid and is injected high and in small volume, and the patient's muscle tone is not reduced by general anæsthesia

Radiography after experimental injection of a radio-opaque sclerosing fluid similar to that used by Boyd (1948) showed that the fluid passed very rapidly into the deep veins through competent communicating veins in the upper thigh In the deep veins this spill is rapidly diluted and dispersed, and damage to valves is likely to be minimal If the fluid is injected at a high level, escape through high communicating veins will only tend to damage the upper femoral or iliac valves, which in almost all cases are already demonstrably incompetent This, of course, does not happen if the fluid is injected below the knee, as advised by Boyd and Robertson (1947), when many deep vein valves may trap the sclerosant and be damaged

Location of Communicating Veins

Numerous tests, all theoretically sound, have been described for the location of incompetent communicating veins All regard the venous system of the lower limb as if it were a large U tube with a varying number of inter communications between the two limbs—the saphenous vein and the femoral vein—running more or less horizontally But this is not so The course of communicating veins may be long and tortuous They are of two types (Warwick 1931) (1) direct, commonly relatively short, and often paired (fig 2), which connect the main saphenous trunks with the main deep veins, and (2) indirect, usually tortuous, and oblique, which unite tributaries of the saphenous veins with the deep veins via their intramuscular tributaries (fig 2) Though there are certain sites at which direct (Boyd and Robertson 1947, Wright 1950) and indirect (Gay 1868, Cockett and Jones 1953) communicating veins are commonly found, there is no constant number or location of either type

Œdema, the coarse subcutaneous fat above the knee, induration below the knee, the high tension in the incompetent saphenous vein on straining, and the presence of two bones in the deep compartment of the leg often make adequate compression of the superficial veins with a tourniquet difficult or impossible without seriously impeding the flow in the deep vessels The tourniquet tests of Ochsner and Mahorner (1936), Perthes (1895), and Slavin (1948) have all been tried but found lacking for the reasons detailed In more than one patient with gross superficial varices a pneumatic tourniquet was placed about mid-thigh and pumped up to a pressure of 140 mm Hg and then a small volume of 25% 'Pyelosil' was injected into the saphenous vein above the tourniquet, which was slowly deflated while the limb was watched on the X-ray screen In many cases, at a pressure of 100–120 mm Hg, the pyelosil was seen falling down inside the tourniquet—the patient was standing erect but not straining This provides a clear demonstration of the fallacy of believing the tourniquet to be "tight enough to occlude only the superficial veins without impeding the flow in the deep vessels."

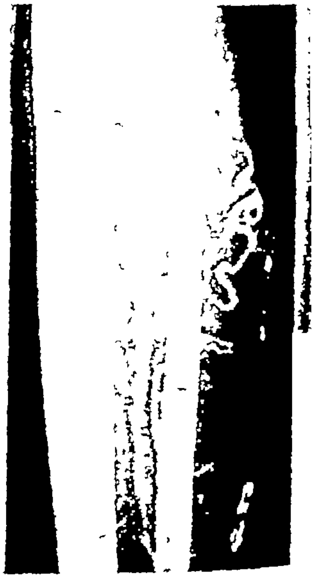


Fig. 2—Ascending venogram showing paired direct and tortuous indirect communicating veins.

The most accurate method of locating communicating veins is venography, but this is expensive and time-consuming and to be of value requires a special and not easily acquired technique (Dow 1951) Though it is possible to demarcate accurately by venography the anatomical distribution of communicating veins, it is by no means easy to demonstrate convincingly which are incompetent

In cooperation with Dr J D Dow comparisons between clinical, venographic, and operative findings were made in a large series of cases of varicose veins, and the following *practical clinical method* of locating communicating-vein incompetence was developed

The Trendelenburg test is first applied to demonstrate the presence or absence of abdominal reflux The test is then repeated, and the pressure at the fossa ovalis maintained for a full minute while the superficial veins are observed If there re no grossly incompetent communicating veins, the super icial veins fill slowly and uniformly from below If superficial rarices appear immediately or rapidly the leg segment is noted and also whether there is obvious reflux from above ese level

The patient is then instructed to exercise the calf muscles actively If the varices become more full and tense the communicating vein valves are incompetent. If the superficial varices fill from above the knee the level of digital compression is lowered to the level of the adductor tubercle and its adequacy is tested by applying the cough impulse test with a watching finger on the line of the main trunk distally and the test is repeated The actual site of emergence of the communicating vein through the deep fascia can often be felt with a finger tip especially in the case of indirect communicating veins.

If such a fascial defect is felt, the test is repeated with one finger occluding the main trunk at the fossa ovalis and another the defect in the deep fascia If this lower finger is at the site of emergence of the incompetent communicating vein the varices will not appear until the finger is removed. In cases where the Trendelenburg test is negative this latter test is still applicable.

Cockett and Jones (1953) have drawn attention to the importance of incompetent indirect communicating veins in the lower third of the leg and noted their relationship to the site incidence of certain gravitational ulcers, as was noted by Gay (1868) in his post-mortem dissections. But not all ulcers occur at these sites, and not all patients who have such communicating veins develop ulcers. Demonstrably incompetent communicating veins should be sectioned deep to the deep fascia, and the defect in that layer sutured (Wright 1950) Wounds in the indurated gaiter zone can be very troublesome, and healing a lengthy process. Dissection in the subcutaneous tissue should be avoided as far as possible, and the communicating veins secured beneath the deep fascia, where dissection is much more easy (Wright 1950) Excision and primary suture suggested by Cockett and Jones (1953) is likely to lead to many troublesome wounds and can rarely be advisable or applicable

Subcutaneous stripping (Mayo 1906) of the main internal saphenous trunk will sever direct communicating veins, but the more important and troublesome indirect communicating veins will rarely be affected. This appears to be a definite defect of this popular method of eliminating superficial varicosities. Further it leaves the defects in the deep fascia through which further blow outs can develop

Deep Veins

Whereas the superficial veins can be easily and directly studied the assessment of the state of the deep veins is difficult and their rôle in the ætiology of gravitational ulcer has occasioned considerable comment (Homans 1916 Bauer 1940 Anning 1950) Many regard permanent deep-vein blockage to be the usual late result of deep thrombosis, and associated varicosities of the superficial veins as an overdistended but necessary collateral circulation (Franklin 1937, Ochsner and Mahorner 1939 Rogers 1939 Coombs 1940 Foote 1944 Anning 1950, Rivlin 1951) But not all cases of previous deep vein thrombosis develop varices, and seldom is there evidence of multiple blow outs of communicating veins, which would be necessary to permit reflux into the superficial veins at all levels of supposed blockage Further the direction of blood flow in superficial varices is retrograde when the upright posture is assumed, and usually freely so on coughing or straining

The incidence of varices and the time-incidence of thrombosis or phlebitis in 284 consecutive cases of gravitational ulcer seen at the varicose vein clinic in the Western Infirmary Glasgow is shown in table I. In only 37 cases was there definite or presumptive evidence of preceding deep thrombosis, and in 27 of these the patients had noted superficial varices before the incident of deep thrombosis. In 48 there was a history of antecedent superficial phlebitis but in only 3 of these cases did the patient claim that the varices followed the phlebitis In a separate series of 35 cases of puerperal white leg in 1925–45 only 16 of the patients had any sign of superficial varicose veins and, of these, 6 stated categorically that their varices had been present for several years before the incident of puerperal thrombosis. The remaining 10 stated that their varices followed the thrombosis.

TABLE I—RELATIONSHIP OF PHLEBITIS TO VARICOSE ULCERS

Sex	No of cases	With varices	With history of deep thrombosis	History of deep thrombosis plus previous varices	With varices which followed thrombosis	With previous superficial phlebitis	With varices which followed superficial phlebitis
M	98	95	10	5	2	17	2
F	186	181	27	22	5	31	1
Total	284	270	37	27	7	48	3

I have observed 2 cases in which the femoral vein had been divided and injected in retrograde manner with a sclerosant. In neither case did new varices appear, and the resulting œdema in 1 has been improved by extirpation of previously present superficial varices. The other patient a young adult male has gradually developed an adequate collateral circulation and the œdema has disappeared

After superficial phlebitis occurring naturally or chemically induced, as in the injection treatment of varicose veins, recanalisation of the thrombus is the rule and, in cases of varicose veins can be observed to progress from above downwards. Such thrombus is much more adherent to the vein wall and associated with more severe toxic or chemical damage to the intima than is the 'quiet' thrombus of deep thrombosis, and would be expected to produce more permanent obliteration of the lumen Experience shows that to obliterate permanently the lumen of a vein subject to stress without destroying the entire vein wall is virtually impossible

For these various reasons recanalisation of deep veins is to be expected after deep thrombosis. Though a complete persistent block is not to be expected a reduction in deep vein efficiency is certain and it seems helpful in attempting to formulate rational treatment, to try to assess the degree of this deep-vein insufficiency

Perthes's Test

The popular test used for this purpose—and it is usually regarded as a test for deep vein blockage (Rivlin 1951)—is Perthes's test

> A venous tourniquet is applied below the level of the lowest incompetent perforating vein so as to occlude the superficial but not the deep veins. The patient then walks briskly about for three or four minutes. If the deep veins are thrombosed then the occlusion of the superficial veins by the venous tourniquet has shut off the only route by which the limb blood can return to the heart and as the patient walks, the veins below the tourniquet do not decrease in size and may even swell and cause pain

This test is quite impractical for many reasons the lowest incompetent perforating vein may be at or below ankle level, the induration of the lower leg may make compression of the superficial veins with a tourniquet impossible without so impeding both arterial inflow and deep venous return as to cause pain and distension of varices without exercise and venous reflux in incompetent varicose veins on exercise can cause distension below an inefficient tourniquet. A modification of this test was used in the location of incompetent communicating veins, themselves an indication of deep incompetence, but it could not be used to assess the degree of deep vein insufficiency of other nature.

In a postphlebitic limb with varices, if the main varicose trunk is occluded at the saphenofemoral junction and the limb is elevated, the veins empty rapidly Similarly, if a varicose segment is isolated between two superficial tourniquets (Warwick 1931) and the limb is elevated, the loop rapidly empties Both these tests demonstrate that a deep venous circulation is patent, this may be either a recanalisation of the previously thrombosed veins or a collateral circulation At operations for varicose veins in postphlebitic cases, if opportunity is taken to explore the femoral vein, in many cases it appears normal, in others it is thickened and matted to the femoral sheath, but even in such cases blood-flow in the vein can always be demonstrated by digital stripping, showing that at least partial recanalisation of the main vein is usual

Venography

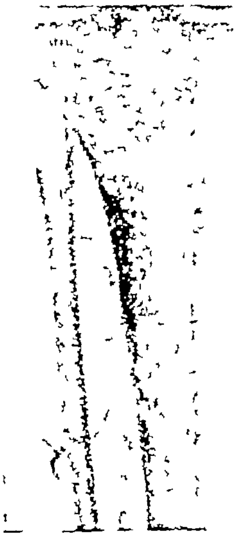

Fig 3—Ascending venogram in patient who had deep-vein thrombosis 17 years previously and gravitational ulcer for 10 years showing patent deep trunk indistinguishable from normal

Two further methods of investigating the deep veins have been advocated venography and pressure tests By ascending venography, provided a proper technique is used to compress the superficial-veins, a patent main deep trunk is invariably demonstrable (fig 3), it is impossible to decide definitely on the efficiency of this deep trunk The technique, difficulties, and interpretation of ascending and descending venography of the deep veins have been very thoroughly discussed by Dow (1951) There appears to be no constant relationship between venographic appearances and the clinical severity of post-thrombotic sequelæ The technique is difficult and time consuming, and is valuable only as a means of confirming impressions of pathology It adds nothing to the problem of treatment, nor is it profitable as a routine investigation

Pressure Tests

The pressure in the veins of a normal lower limb at rest corresponds to a column of blood from the level concerned to heart level (Smirk 1936, Pollack and Wood 1949, Walker and Longland 1950) Thus, the pressure in a vein of the foot in a man of average height standing at rest is about 90 mm Hg During exercise the muscle-cuff pump lifts the blood from the foot towards the heart, and in normal people the pressure in a foot vein falls to about 20–30 mm Hg In varicose veins, on exercise, varying abdominal pressure forces blood down the saphenous vein by reflux, and the pressure fall on exercise may be small or nil, or there may be a fluctuating rise If a tourniquet is applied below the knee (Walker and Longland 1950) to prevent such reflux, the exercise fall is near normal, but very variable results are obtained because of the usual venous tourniquet difficulties

Theoretically, in deep vein insufficiency, if the superficial reflux could be eliminated without affecting the deep return, the height of the pressure reading on exercise above normal would be a guide to the degree of stasis in the deep circulation—i e of deep insufficiency Unfortunately in the cases where this test might be of most value the presence of high tension varices and, especially, the gross induration of the lower limb and reflux through incompetent communicating veins below the knee render the test invalid The procedure, involving intubati of a superficial vein on the dorsum of the foot with 'Polythene' tube filled with citrate solution and co nected to a manometer, is clearly not a simple bedsi or outpatient procedure Being subject to so ma fallacies it was abandoned after a brief trial because did not provide any information not already known

It becomes clear that there is no test of deep-ve insufficiency of real practical value But cases of gra tational ulcer can be classified in three groups of ascendi difficulty in management

(1) Cases with superficial varicose veins and no history deep thrombosis

(2) Cases with superficial varicose veins and a history deep thrombosis

(3) Cases with no varices and a history of deep thrombos

Alternatively another classification might be follows

(1) Deep vein incompetence with no impediment to de return other than venous reflux

(2) Deep vein incompetence with impediment to de return in addition to reflux.

Scheme of Treatment

On the basis of the foregoing conclusions the followi standard method of management of gravitational ulc was adopted in 284 consecutive cases

(1) The ulcer was encouraged to heal by applying a pr tective non adhesive dressing of tulle gras Over this w applied a pad of orthopædic felt to exert local pressure, t disperse œdema, and so to help restore the local vascularit and the limb was firmly encased in a semi rigid boot 'Viscopaste' from the base of the toes to just below the kne Such dressings were applied weekly until œdema was disperse and then less frequently until the ulcer healed or became stati No antiseptics were used, nor did they seem necessar Viscopaste was preferred to 'Elastoplast' because it is eas to apply and less likely to cause distressing skin reactions. a skin reaction did develop, the limb was swathed in gau soaked in 5% 'Ichthyol' in calamine lotion, and the visc paste was applied on top The patient was kept ambulant encourage deep venous return.

(2) Superficial varicose veins were treated by appropria ligation and retrograde injection of sclerosant solution. almost all the cases this was an outpatient procedure do under local anæsthesia

(3) Demonstrably incompetent communicating veins wer divided beneath the deep fascia, which was then sutured.

(4) Deep venous return was encouraged by the provisio of semi rigid viscopaste support and by keeping the patien ambulant, by encouraging reduction of obesity, and b providing elastic stockings to be worn after healing had bee achieved

As will be recounted later, further measures were onl applied if the standard treatment failed or was foun inapplicable

Table II shows the treatment applied in this series, an table III a comparison of results with other publishe series It must be emphasised that the present series from a varicose-vein clinic and contains a very hig proportion of cases with superficial varices, in othe series the incidence of varices may be much lower, and o previous thrombosis much higher This will influence th success-rate very considerably

TABLE II—METHODS OF TREATMENT

Treatment	No of patients		
	Men	Women	Total
High ligation and retrograde injection	35	62	97
High ligation retrograde injection and communicating vein ligation	49	102	151
Communicating vein ligation alone	4	4	8
Support alone	9	14	23
Skin grafting	—	4	4
Deep vein ligation	1	4	5

Though dispersal of œdema and support of the muscle cuff formed the initial basis of treatment two additional observations emphasise the value of elimination of coexisting superficial varices

It is well known that gravitational ulcers naturally tend to heal with rest in bed or support of the limb, and to recur if these measures are withdrawn To try to assess the contribution of superficial vein ligation, a series of cases was treated by "immediate ligation and no local support Of 12 cases so treated all were successful, the average healing time being six weeks In none of these cases was there any history of phlebitis

Further corroboration of the value of eliminating the effects of reflux was provided by 6 cases with gravitational ulcer superficial varices, and a negative Trendelenburg test (table IV) In none of these was there a history of antecedent thrombosis or phlebitis, and in all of them sound healing of the ulcer followed ligation and division of incompetent communicating veins The site of the blow-out varied in 4 cases it was on the calf and in the remaining 2 it corresponded to the posteromedial indirect communicating vein described by Cockett and Jones (1953) Warwick (1931) and Gay (1868) These cases confirm the value of the elimination of local reflux into the superficial veins.

Examination of the 14 cases in which ulceration recurred after healing revealed blow outs in 11 of them. In all of these appropriate ligation led to healing Of the remaining 3 patients 2 have been subjected to femoral vein ligation combined with skin grafting with ultimate success in 1 the other patient underwent popliteal vein ligation and skin grafting, with great success.

TABLE III—COMPARATIVE RESULTS

Reference	No. of patients	Remaining healed (%)	Length of follow up (mos.)
Buxton and Coller (1945)	26	87·0	3–6
Linton and Hardy (1948)	84	81·0	1–16
Glasser (1949)	40	72 5	6–48
Bauer (1950)	196	84 0	0–36
Present series	284	93 5	12–60

In 16% there was a recurrence, and almost two thirds of these "seemed to be due to persistent incompetent veins in the superficial system" (Bauer's comment on his series treated by popliteal-vein ligation).

Discussion

The effects of thrombophlebitis in any part of the venous system are damage to the intima, valves, and vein walls, with in the acute phase, complete blockage of the lumen by thrombus. Later as resolution takes place, fibrosis of the valves walls and thrombus produces valve incompetence, loss of elasticity and recanalisation The end result is vein incompetence with narrowing of the lumen—a state of venous insufficiency, compensation for which must be obtained by adequate collateral circulation if a normal venous return is to be achieved. Whether this last can be achieved or not depends largely on the extent of the thrombophlebitis and the previous competence of the affected veins

Deep vein thrombosis may develop in patients with previously normal veins or with superficial varices From clinical observation it seems that the presence of superficial varicose veins, itself an indication of deep vein incompetence (Wright 1952) may well indicate a predisposition to the development of deep vein thrombosis In this series of 284 cases of gravitational ulcer there was a history of definite or probable deep vein thrombosis in 31 and 27 of these had a clear history of previous varicose veins. In only 7 did the history indicate that the varices had followed the thrombotic incident.

The damage to the deep veins inflicted by thrombosis is essentially threefold (1) loss of valves, allowing venous reflux ; (2) loss of calibre, causing impediment to blood flow, which will affect both onward flow and reflux ; and (3) loss of elasticity, diminishing the efficiency of the massaging effect of the muscle cuff pump

TABLE IV—CASES TREATED BY LIGATION OF COMMUNICATING VEINS

Case no	Duration of ulcer	Site of blow-out	Period healed (yr)
1	10 yr	Calf	4
2	6 wk.	Calf	5
3	4 mos.	Calf	2–5
4	3 yr.	Ankle	3
5	2½ yr	Calf	5
6	2 wk	Ankle	4

Bauer (1940) believes that the superficial venous system represents the usual collateral return in blockage of deep veins by thrombosis His claim (Bauer 1946) that recanalisation hardly ever takes place after deep thrombosis and that 'for the rest of life drainage is from deep to internal saphenous vein and upwards is based on his venographic studies and is contrary to necropsy (Gay 1868) and clinical findings (Warwick 1931) Dow (1951) never failed to show a patent deep circulation in post thrombotic legs, provided he compressed the superficial veins enough to force the radio opaque fluid into the deep veins. Bauer (1950) also claimed to be able to demonstrate deep vein incompetence by retrograde venography, and other workers have made similar claims. Dow has clearly shown that the appearances described by Bauer as indicating deep vein valve incompetence may be obtained in normal limbs when Bauer's technique is used It seems unreasonable to assume that a sudden tilting of the patient to 45° should cause the blood flow in the femoral vein to cease. Indeed if the femoral vein is opened at operation and the proximal end occluded profuse hæmorrhage leaves the witness in no doubt of the continuing upward flow of blood from the limb Further, the retrograde venogram is not a picture of a flowing stream but of a dense radio-opaque fluid percolating downwards through an upward flowing stream of blood.

Deep vein ligation and split skin grafting were only used in this series if elimination of superficial vein reflux and stasis plus elastic support failed to achieve sound healing and to compensate for the continuing deep vein defects. Interruption of the deep veins has had many advocates (de Takats et al 1929 Leriche 1926 Buxton and Coller 1945 Linton and Hardy 1948 Bauer 1948 Glasser 1949) Though there is no doubt that recanalisation is the rule after deep thrombosis the resulting lumen is narrowed tortuous, and valveless and the vein wall is thickened rigid, and matted to the artery and often to the accompanying nerves, all of which share in the inflammation. Thus, nerve irritation artery irritation lymphatic involvement, and sympathetic-*nerve involvement may all play a part in the production* of signs and symptoms It is consequently difficult to assess the results of the various procedures advocated for the relief of deep vein insufficiency Single interruption at any level will only prevent reflux at that level, and reflux via collaterals may still take place.

In my limited experience the most constant effect of deep vein ligation has been relief of bursting pain this suggests a nerve section effect presumably sympathetic Postoperative flushing of the foot and ankle in these cases also suggests a sympathetic nerve-section effect Œdema has never completely subsided

If reflux were the only deep vein defect deep vein ligation would seem to be a sound procedure although it would usually require to be done at several levels to defeat the effect of by passing Deep venous reflux as a primary defect may lead to the development of superficial varicose veins but many cases with extensive superficial varices never develop ulceration, and those that do always show evidence of some preceding thrombosis of at least a perforating vein Deep thrombosis may be followed by gravitational ulceration in limbs where there are no superficial varices Thus it seems that the determining factor in the production of ulceration is something more than incompetence of deep or superficial veins—i e , deep-vein insufficiency the result of thrombosis When there is superficial vein as well as deep-vein insufficiency, the removal of the effects of the former proves beneficial to the limb and may so relieve stasis as to permit sound healing of gravitational ulceration and reduction in œdema and induration Varicose veins are not a cause of ulceration All gravitational ulcers are postphlebitic, although there may be no history of characteristic deep-vein thrombosis and the extent of the deep phlebitis may be quite localised

The nature and degree of deep-vein insufficiency cannot be accurately assessed or located clinically or by ancillary methods Reflux in superficial and communicating veins can be prevented by vein section, but to apply this procedure to deep veins produces a block not only to deep vein reflux but also to the deep venous return The collateral circulation established to circumvent such a block may in turn be submitted to the strain of femoral or iliac valve incompetence and itself become incompetent Fibrosis and loss of calibre, the result of thrombosis, will stimulate the opening up of a collateral circulation, and it seems that this can best be aided by supporting the muscle cuff and eliminating the effects of gravity Rest in bed is economically impossible for many of these patients and in any case tends to encourage stagnation Ambulatory treatment seems the most reasonable prophylactic against deep-vein stagnation, just as continued elastic support seems to be the fundamental requirement of treatment

Summary

The factors responsible for venous stasis in the lower limb are discussed, and the particular importance of valve competence and the massaging effect of the muscle cuff of the leg are emphasised

Superficial varicose veins are a consequence of deep vein insufficiency, which in certain cases also causes œdema, induration, and ulceration

Methods of demonstrating and locating the sites of reflux into the superficial veins are described Such reflux can be prevented by appropriate vein section

The value of sclerosant injection in the elimination of stasis in the superficial veins is considered Damage to the deep veins is unlikely if the sclerosant is viscid and is injected high and in small volume

The effects of thrombosis on the deep veins are diminution of lumen, increased rigidity, and loss of valves Recanalisation is the rule The value of venography and pressure tests in attempting to assess the state of the deep veins is critically discussed Neither procedure helps in the problem of treatment

284 cases of gravitational ulcer were treated by elimination of superficial varices and with semi rigid supporting bandages 93 5% remained healed for 12–66 months

I wish to thank Dr J D Dow for his coöperation and for the radiographs, and Prof C F W Illingworth for his advice and helpful criticism in the preparation of this article

VAGINAL BLEEDING DUE TO POTASSIUM PERMANGANATE

Elliot E Philipp
M.A., M B Camb , F R C S , M.R C O G
CONSULTANT OBSTETRICIAN AND GYNÆCOLOGIST TO OLDCHURCH HOSPITAL, ROMFORD, ESSEX , CONSULTANT GYNÆCOLOGIST TO THE FRENCH HOSPITAL, LONDON

THE relative scarcity of published reports of traumatic vaginal hæmorrhage due to ulceration by potassium permanganate gives a wrong impression of the true incidence of a not uncommon condition Doctors who see cases do not often report them , but, since the bleeding can be so copious as to threaten life, it has been thought advisable to publish this new series of cases.

Potassium permanganate is a common disinfectant, and common disinfectants tend to be introduced into the vagina This does not matter much, so long as they are adequately diluted, but in strong concentrations any antiseptic can cause disaster to the woman using it.

It is believed that potassium permanganate in contact with the moist vaginal wall is broken down to potassium hydroxide (caustic potash) and to manganese oxide or oxides The potassium hydroxide causes deep ulceration, and the manganese oxides can have severe toxic effects The ulcers bleed, giving rise to deceptive and sometimes dangerous hæmorrhage

In 1951–53 eleven patients who had had vaginal bleeding following the misapplication of potassium permanganate were admitted to Oldchurch Hospital. One would have lost her life if a blood transfusion had not been given on admission and if the correct diagnosis of the condition had not been made This minor epidemic resulted from a local belief that potassium permanganate tablets or crystals could bring about abortion

The tablets and the crystals were bought by the patients at two local chemists, but one patient received the tablets from her mother as a gift on her wedding eve The permanganate produced severe burning where it settled in the solid state , in the vagina clean but very indolent ulcers resulted and small arteries were eroded, with resultant bleeding that was sometimes difficult to arrest Secondary hæmorrhage was a feature of the severer burns, and healing was accompanied by thick scarring

As an abortifacient potassium permanganate is virtually useless, for abortion rarely results unless a permanganate

solution is introduced into the uterus There are only two reported cases of intra-uterine douching with saturated potassium permanganate solution These were reported by Jetter and Hunter (1949), and in both of them the douching proved fatal to the mother The permanganate was shown to be not only an ulcerating agent and a burning agent but also a hæmolytic agent

In reports from other sources it has been suggested that heavy bleeding from the vagina in association with an enlarged pregnant uterus misleads the unwary gynæcologist into diagnosing inevitable abortion and perhaps even performing uterine curettage.

At Oldchurch Hospital conservative treatment of abortion is practised, and those women who bleed and whose bleeding is not soon controlled are carefully examined in the ward to exclude trauma of any sort before surgery is contemplated Even in inevitable abortion conservative measures are usually taken Thus, all the cases of potassium permanganate burns in the present series were diagnosed by discovery of the ulcers in spite of the almost invariable absence of a history of trauma. When confronted with the diagnosis all the patients confirmed it.

The treatment consists in removing the tablets or crystals washing away the manganese oxides that have formed and taking any steps necessary to control the hæmorrhage. Surgery may be necessary to undersew the ulcers with deep mattress stitches—which can be difficult, because the ulcers are often situated in the highest part of one of the lateral fornices.

Illustrative Case records

Case 1.—A married woman, aged 28 was admitted on Dec. 25, 1951 When her period was a week overdue the patient used a ' potash ' tablet and next day had a fairly severe primary hæmorrhage. A week later further bleeding started. When she was admitted to hospital a deep ulcer on the posterior wall of the vagina and another on the anterior lip of the cervix were found The patient's pulse-rate was 116 It was estimated that she had lost more than 2 pints of blood, and, as the bleeding was continuing briskly the ulcers were sutured in the operating theatre under general anæsthesia. A pint of 'Plasmosan' and a pint of blood were transfused. Two days later the hæmoglobin was 54%. The patient was discharged on Jan. 6, 1952.

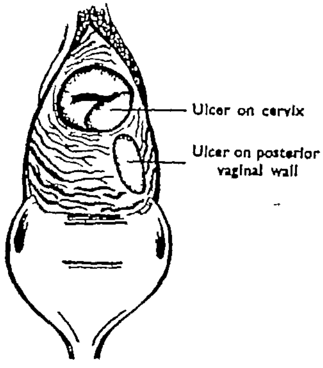
Case 2.—A married woman, aged 29 was admitted on April 3 1952. When her period was four weeks overdue she took twelve Dr Armstrong's pills ' A few hours later she inserted some potassium permanganate crystals on cotton wool into her vulva. Within a few minutes she felt a very acute burning sensation in her vulva and vagina, and later in her abdomen and back. When she was admitted to hospital, her labia were œdematous. There was so much pain that it was impossible to pass a speculum Under general anæsthesia the crystals which had been converted into black manganese oxides, were removed and the vagina was washed out with a ½% solution of cetrimide. Flavine emulsion dressings were applied to the labia and lower vagina. These dressings were changed daily For the first few days every change of dressing caused slight bleeding. The patient was three weeks pregnant on admission and eight weeks pregnant on discharge on May 12.

Case 3.—A married woman, aged 32, was admitted on May 27 1952. When eight weeks pregnant she inserted a potassium permanganate tablet high into her vagina. This caused such profuse bleeding that two days later her doctor thought he saw the fœtus passed. When the diagnosis had been made after admission to hospital, the vagina was packed. When the pack was removed, the reactionary hæmorrhage was so severe from the right side of the cervix and the right vaginal wall that the ulcers had to be undersewn under general anæsthesia. The patient remained pregnant. She was discharged on June 8.

Case 4.—A married woman, aged 37, was admitted on July 18, 1952 She had inserted permanganate crystals into her vagina during the eighth week of her pregnancy A burning sensation and severe pain resulted. Her temperature was 103.4 F hæmoglobin 66% Treatment consisted in douching with warm water until all the crystals were dissolved away Chloramphenicol therapy was given. The patient was discharged on July 30 She remained pregnant and was delivered on March 1 1953 of a normal full size male infant The delivery was normal in spite of some scarring of the lower part of the vagina.

Case 5—A married woman aged 28, was admitted on July 31 1952 When her period was two days overdue she inserted a tablet of potassium permanganate into her vagina, and she was admitted a few hours later There was only slight vaginal loss, and this soon ceased The registrar who examined her had never seen the condition before He noted that she had a slight ulcer on her cervix but doubted whether she was pregnant. He discharged her from hospital six days after admission.

Two days later on Aug 7 the patient was readmitted virtually moribund Her blood pressure was 60/40 mm Hg Her pulse-rate was uncountable, and she was suffering from air hunger An immediate transfusion with two pints of plasmosan and a pint of blood was given before the patient was fit enough to be taken to the operating theatre There two ulcers were found, one on the cervix and one in the vagina; these were undersewn (see figure) and the vagina was packed. Next day the patient's temperature was 104°F On Aug 13 a loss recurred and persisted till Aug 15 when a further blood transfusion was necessary and the patient was returned to the operating theatre where under general anæsthesia the ulcers were re-sutured, this time with Nylon sutures. A urinary infection developed and was treated.



Ulcers in case 5 seen on examination with vaginal speculum.

The patient was discharged from hospital on Aug 30 after removal of the nylon stitches. She had not been pregnant at all. The absence of pregnancy was confirmed at the second operation, when blood was seen to be issuing from the cervix and normal menstrual curettings were obtained.

Case 6.—A married woman, aged 32, was admitted on July 29 1953 When her period was two weeks overdue she inserted a potassium permanganate tablet into her vagina. Her doctor diagnosed cervicitis he prescribed ethisterone to stop the bleeding and this treatment appeared to have been fairly successful in that the hæmorrhage which had been heavy on July 15 virtually ceased fourteen days later

When the patient was seen at the gynæcological clinic, a typical potassium permanganate ulcer was found in the right fornix. From fear of secondary hæmorrhage the patient was admitted to the ward Hæmoglobin was then 94%. No treatment was given.

On Aug 6 she was examined with a speculum to ascertain whether it was safe to discharge her This manœuvre caused a sudden blood loss of three pints. The bleeding ceased on the administration of morphine just before arrangements were completed to take the patient to the operating theatre. Four days later the hæmoglobin was 53%. Intravenous iron therapy was given. Further examination with a speculum on Aug 19 showed scarring in the right fornix There was no further bleeding

On Sept. 3 the patient was seen in the follow up clinic. She was still pregnant, her uterus being enlarged to the size of an eight-week pregnancy

Discussion

This condition is by no means new Its introduction into this country is blamed on the Americans, probably unfairly, but the first cases reported in England seem to have been in the vicinity of American aerodromes Not many reports have been published on this subject, but I have found fourteen in French and Italian written in the last ten years, and six in English On the Continent the condition seems to be fairly well recognised. The largest series reported, however, comes from America, where McDonough (1945) saw sixty-five cases, of which six ended in abortion Of ten cases seen by Lubin and Waltman (1951) between 1946 and 1949 only one ended in abortion Miller (1951) reported some ten cases from the Croydon area, and Henderson and Watt (1951) said they had seen several cases, three of which had required cæsarean section because of late scarring of the vagina The ulcers always heal with scarring

In an attempt to stop the misuse of potassium permanganate which started in the Romford district five or six years ago, my predecessor informed the police in 1951, and only one case occurred in that year I informed the police towards the end of 1952, and they tried to discourage the sale of potassium permanganate (by methods best known to themselves) There are no legal grounds for prohibiting the sale, so a new case was seen, after an interval of ten months, in 1953

The main danger of the condition lies in the fact that the diagnosis can be so difficult, because even fairly careful examination with a speculum by a doctor unfamiliar with the condition may fail to reveal an ulcer in the fornix of a lax vagina A further danger is the indolence of the ulcers and the fact that if they are even slightly disturbed, as by passing a speculum (as in case 6) or by intercourse, they may bleed profusely and the patient may be in danger of losing her life

In the present series no patient died, but one was quite lucky to escape with her life and had to have two operations All the patients were married Two aborted, neither as a result of using potassium permanganate I have seen stenosis of the vault in a patient who was treated at Oldchurch Hospital for potassium permanganate burns in 1949, and it is quite possible that stenosis will develop in some of the cases reported here

The accompanying illustration was drawn by one of our London Hospital medical students, Mr H M. Thomas, and it is taken from the operation findings at the first operation on case 5 I wish to thank Mr John D Watt, my senior colleague, who told me about the condition and made the diagnosis for me in the first case I saw, Sister J Holmes, of B2 Ward, Oldchurch Hospital, for her care in nursing all these patients, and Mr G H Bancroft-Livingston, who helped me in the preparation of this paper

Addendum

Since preparing this paper I have seen three further cases admitted to hospital, and a fourth case not requiring admission This brings the number of cases in this series to fifteen

One of the patients admitted was the first in this series to attain her aim she persuaded the registrar to curette her as a case of inevitable abortion It was only on removing the Auvard speculum and completing the curettage that he found the vaginal ulcer situated 1 in from the vulva and bleeding heavily This ulcer had caused a large blood clot to form, filling the vagina and the external cervical os In this case a therapeutic abortion would possibly have been justified, for the patient was an ill woman with two young children, who at the onset of her pregnancy already had such complex rhesus agglutinins that her blood had to be cross matched with that of seven donors to find the pint of fresh blood that eventually saved her life

In a valuable recent paper Alment and Nicol (1953) reported five cases, and rightly pointed out that the permanganate lesions could be confused with primary chancres

TREATMENT OF MEGALOBLASTIC ANÆMIAS

RELATION OF PENICILLIN TO VITAMIN B_{12}

Henry Foy
M.A, Ph.D, D Sc Oxfd
Athena Kondi
M D Athens
Of the Wellcome Trust Research Laboratories

We have previously reported the responses of the megaloblastic anæmias in Africans to oral or intramuscular penicillin (Foy et al 1951, 1952a, b, and c), and shown that these responses in every way resemble those obtained in similar types of anæmia by the use of potent hæmatinics

It is well known that whereas all megaloblastic anæmias respond to folic acid, not all respond to vitamin B_{12} In this paper we show that those anæmias which do not respond to penicillin do not respond to vitamin B_{12} by mouth, and we suggest that penicillin acts in the megaloblastic anæmias by stimulating the biosynthesis of vitamin B_{12} by the intestinal microflora

All the cases selected for treatment were severe megaloblastic anæmias with red cell counts of 500,000–2,500,000 per c mm, megaloblastic bone marrow, giant stab-cells, and the mean corpuscular volume (M C.V) 80–140 c µ In most of them an increased amount of bilirubin was shown by the indirect test, and Schumm's test for plasma hæmatin was positive Previous experience showed us that these anæmias always responded to crude liver or to folic acid, and often to oral or intramuscular vitamin B_{12} Some of them had histamine fast achlorhydria, and of these a few, on gastroscopy, had signs of gastric atrophy (Woods 1951) and must therefore be regarded as pernicious anæmia, although they had no nervous involvement or sore tongues

All our patients were kept under observation for three to ten days before receiving any treatment, if their reticulocytes did not increase during this time, they were selected for treatment A positive response to treatment was indicated by an increase in the number of reticulocytes to the maximum for the blood-count in six to twelve days, by a doubling of the blood-count and hæmoglobin in fourteen to twenty one days from the start of treatment, and a change in the marrow from the typical pre treatment megaloblastic type to the characteristic normoblastic erythroblastic picture of normal marrow

Classified according to their response to treatment, there appear to be at least three types of megaloblastic anæmia among Africans

Type 1 responds to penicillin, to oral and intramuscular vitamin B_{12}, to folic acid, and to liver

Type 2 does not respond to penicillin or to oral vitamin B_{12}, but still responds to intramuscular vitamin B_{12} and to liver

Type 3 responds only to folic acid or to crude liver

Clinically and hæmatologically we could not see any difference between those cases which responded to penicillin and those which did not.

Up to now we have treated 24 cases of megaloblastic anæmia with penicillin Of these, 16 gave typical and specific responses 4 did not respond to either penicillin or oral vitamin B_{12} but did respond to intramuscular vitamin B_{12}, and 4 did not respond to penicillin or to either oral or intramuscular vitamin B_{12} but did respond to oral folic acid

Representative Case records

TYPE 1

Double Response to Oral Penicillin

Case 1 (fig 1).—A female Kikuyu aged 24 well nourished and of good physique entered hospital on March 24, 1952, complaining of weakness dyspnœa and pains all over the body She had given birth on March 6 to a child whom she was breast-feeding, and in the usual African way she continued to do so throughout her stay in hospital She said that she had become ill during the last month of her pregnancy

On examination her spleen was enlarged to the umbilicus, her liver was not palpable and she had slight œdema of her ankles her tongue nails, teeth, and nervous system were normal Her lungs and heart showed nothing that was not compatible with her extreme anæmia. Her temperature was 100 F and she had a slight cough

Blood examination on March 25 1952 showed: red cells 845,000 per c.mm; Hb 2·8 g per 100 ml; M.C.V 118 c.μ; mean corpuscular Hb (M.C.H.) 33 μμg mean corpuscular Hb concentration (M.C.H.C.) 28% bilirubin (indirect) 3 mg per 100 ml white cells 2140 per c.mm. no sickling no malaria parasites Kahn test negative

Sternal puncture (March 25 1952) showed an active marrow, with intermediate megaloblasts and giant stab-cells.

Gastric test normal after histamine 1 mg

Treatment and progress.—The patient was kept under observation from March 24 to March 27 1952 during which time her reticulocytes never increased beyond 0·7% From March 28 to March 31 she was given oral penicillin 200,000 units daily By March 31 her reticulocytes had increased to 32%. On April 2 blood examination showed red cells 1 000 000 per c.mm., Hb 3·8 g per 100 ml and M.C.V 135 c.μ During the following eleven days the reticulocytes decreased to 1% On April 3 diarrhœa developed, which was cleared with kaolin As the red-cell count on April 14 was still only 1 430 000 per c.mm the Hb was 4·8 g per 100 ml and the marrow still contained some intermediate megaloblasts, another course of oral penicillin 200 000 units, was given from April 14 to April 22 By April 20 the reticulocytes increased to 20% On May 6 1952 the patient left hospital with a red cell count of 2 000 000 per c.mm. Hb 9 g per 100 ml and a normal bone marrow

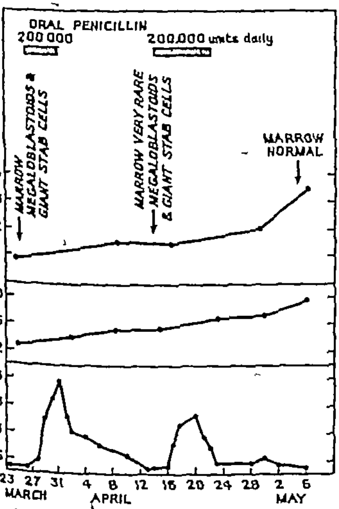

Fig 1—Type-I anæmia showing double response to oral penicillin (case 1)

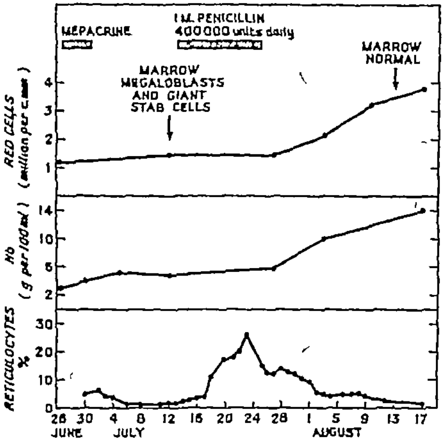

Fig 2—Type-I anæmia showing response to intramuscular penicillin (case 2)

Response to Intramuscular Penicillin

Case 2 (fig 2).—A male Mkamba student aged 19 well nourished and of good physique, entered hospital on June 25 1952, complaining of headache abdominal pain, diarrhœa, and weakness.

On examination his temperature was 103°F spleen 2 (Hackett) and liver palpable and tender His tongue teeth, nails, and central nervous system were normal His red cells were 1 160 000 per c.mm and Hb 2·8 g per 100 ml Falciparum rings were present so a five-day course of mepacrine was given. On recovery from malaria he was found to be severely anæmic and was referred to us on June 30; he was kept under observation, without treatment until July 12.

Blood examination on July 12 showed red cells 1 340 000 per c.mm. Hb 3·8 g per 100 ml; M.C.V 88 c.μ. M.C.H. 33 μμg M.C.H.C 31·4% white cells 3100 per c.mm. bilirubin (indirect) 1·1 mg per 100 ml.; Schumm's test +++ no sickling; no malaria and Kahn's test negative

Marrow puncture on July 12 showed great activity with many typical megaloblasts, intermediate megaloblasts, and giant stab-cells.

Stools contained no ova or cysts

Gastric test normal after histamine 1 mg

Progress and treatment.—While the patient was under observation the reticulocytes decreased from 6·0 to 0·2% From July 13 to July 25 he was given intramuscular penicillin 400 000 units daily His reticulocytes reached 24% on July 23, and on Aug 3 his red cells were 2,100 000 per c.mm. and Hb 9·6 g per 100 ml The patient left hospital at his own request on Aug 17 1952 with a red-cell count of 3,800 000 per c.mm and Hb 12·5 g per 100 ml. marrow still very active erythroblastic normoblastic in character but no megaloblasts.

TYPE 2

Response to Intramuscular Vitamin B_{12} Only

Case 3 (fig 3).—A female Kikuyu aged 32, under our observation since November 1950 had during this period four relapses of anæmia. She always had histamine-fast achlorhydria with no pepsin, and well-marked atrophic gastritis, and apart from the absence of nervous symptoms and glossitis was

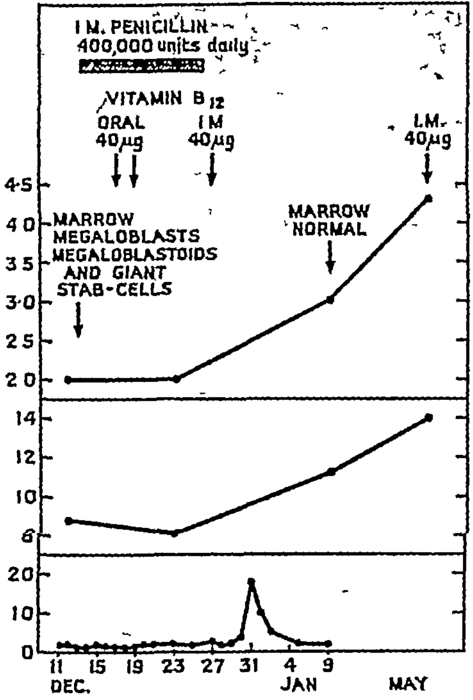

Fig 3—Type-2 anæmia showing response to intramuscular vitamin B_{12} only (case 3)

a typical case of pernicious anæmia. During the first two relapses she was successfully treated with 'Anahæmin' Her third relapse was treated with 80 µg of intramuscular vitamin B_{12}, to which she responded normally Her fourth relapse, which has been fully reported previously (Foy et al. 1952c, case 4), was treated with large doses of penicillin, and at that time we attributed the lack of response to this high dosage. We therefore treated her at the next and fifth relapse with intramuscular penicillin 400 000 units daily

Fifth relapse—She was admitted to hospital on Dec. 11, 1952, complaining of headache, weakness, and palpitations. Her teeth, tongue, nails, and nervous system were normal; she had no œdema, her spleen and liver were not palpable, and her heart and lungs were normal As on previous occasions she was her usual well nourished self

Blood examination on Dec 12, showed red cells 1,960,000 per c.mm., Hb 8 7 g per 100 ml, M.C.V. 122 c µ, M.C.H. 44 µµg, M.C.H.C. 36%, white cells 3020 per c mm., bilirubin (indirect) 3 mg per 100 ml, Schumm's test + + +, no malaria, no sickling and Kahn's test negative

Marrow biopsy showed an active marrow with intermediate megaloblasts, typical megaloblasts, and giant stab cells.

Stools contained no ova or cysts.

Gastroscopy (Dr G C Dockeray) on Jan 3, 1953, showed a pale mucosa with well marked gastric atrophy

Treatment and progress—As the patient had been in our care before, we kept under observation from Dec. 11 to Dec. 13, during which time her reticulocytes showed no variation. From Dec 13 to Dec. 26 penicillin 400,000 i.u. was given daily. On the sixth and seventh days after the start of the course of penicillin she was given 40 µg of vi B_{12} by mouth daily. There was no response to either drug. On Dec. 27 she was given 20 µg only of intramuscular vitamin B_{12}, five days later her reticulocytes increased 19%. She left hospital on Jan 19, 1953, with red cell 2,930,000 per c mm., Hb 11 g per 100 ml, and a normal marrow She visited us on May 8, 1953, with red cells 4,260,0 per c.mm and Hb 14 g. per 100 ml.

Hæmatologically and gastrically the patient appear to be a typical case of pernicious anæmia, and is o interest in that she never responded at any time either to oral vitamin B_{12} or to penicillin, and we believe that the failure to respond was due to complete absence of intrinsic factor, related to her constant and extensive atrophic gastritis and histamine-fast achlorhydria, in contrast to case 4.

Response to Intramuscular Vitamin B_{12}

Case 4 (fig 4)—A female Kikuyu, under our observation since 1949, had six relapses of anæmia.

The *first and second relapses* were successfully treated with 'Neohepatex' in a local dispensary

The *third relapse* was treated with 'Marmite', but, as the patient during this relapse developed pneumonia and was given penicillin, it was difficult to say whether the marmite or the penicillin, or the combination, had produced the remission. At this stage the patient was hypochlorhydric after 1 mg of histamine

The *fourth relapse*, in November, 1950, was successfully treated with intramuscular penicillin alone, and the patient was discharged well, with red cells 4,800,000 per c.mm., Hb 11 g. per 100 ml., and a normal marrow This fourth relapse has been fully described (Foy et al. 1951)

The *fifth relapse* was in September, 1952, when she entered hospital complaining of her usual symptoms, headache, dyspnœa, weakness, low grade pyrexia, and icterus. Her tongue was red at the edges but otherwise normal. Her spleen and liver were not palpable; her teeth, nails, nervous system, heart, and lungs were normal, and she was her usual very well nourished self

Sternal puncture showed active marrow, with intermediate megaloblasts, typical pernicious anæmia megaloblasts, and giant stab cells.

Stools contained no ova or parasites

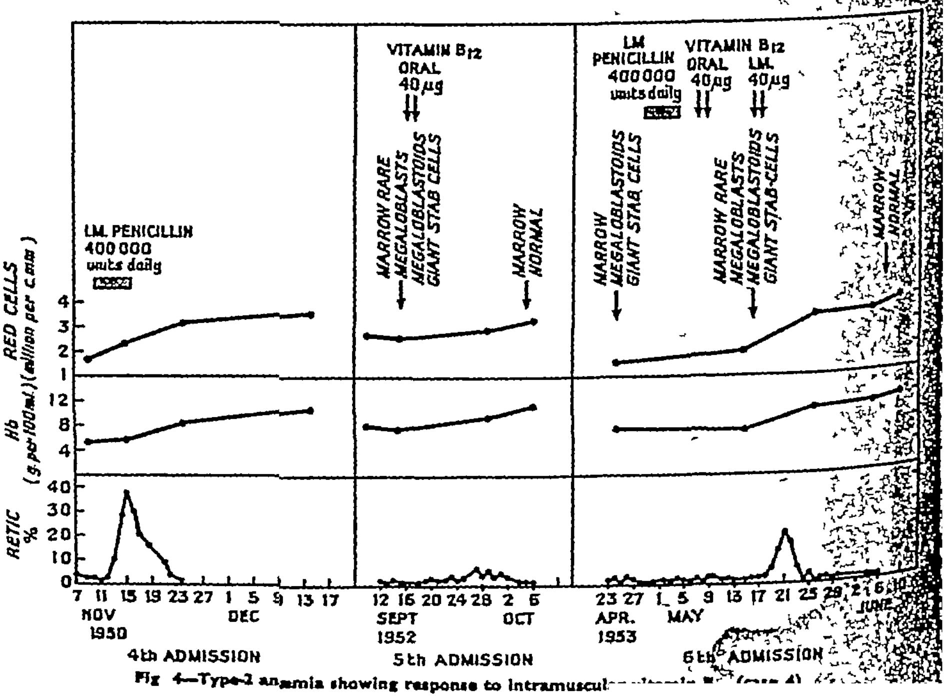

Fig 4—Type-2 anæmia showing response to intramuscul[illegible] (case 4)

Gastroscopy (Dr G C Dockeray) on Oct. 1, 1952 showed a rather anæmic mucosa, which was atrophic and near the fundus slightly greenish grey with prominent blood vessels showing through the mucosa. There was no evidence of erosion or other abnormality. Complete histamine-fast achlorhydria was present.

Blood examination on Sept 15, 1952, showed red cells 2,510 000 per c mm. Hb 8·5 g per 100 ml.; M.C.V. 100 c.µ; M.C.H. 31 µµg, M.C.H.C. 34%; white cells 3000 per c.mm; bilirubin (indirect) 5 mg per 100 ml. Schumm's test ++; no sickling, no malaria, and Kahn's test negative.

Treatment and progress.—The patient was kept under observation from Sept. 11 to Sept. 16, 1952, during which time her reticulocytes varied from 0·7 to 1%. On Sept. 16 and 17 she was given oral vitamin B_{12} 40 µg daily; her reticulocytes showed a submaximal rise to 6%. On Sept 29, 1952, 14 days after the start of this treatment, her red cells were 2 010 000 per c.mm. and Hb 9·5 g per 100 ml. She left hospital at her own request on Oct 7 with red cells 3 140,000 per c mm. Hb 11·6 g per 100 ml., and normal marrow. On Jan. 15 1953 her red cells were 3 910,000 per c.mm. and Hb 13 g per 100 ml.

Sixth relapse.—From October, 1952 to April 1953 she had no treatment and she re-entered the hospital on April 22 complaining of her old symptoms.

Blood examination on April 24, 1953, showed red cells 2,075 000 per c.mm. Hb 8·8 g per 100 ml; M.C.V. 120 c µ; reticulocytes 1·4%; M.C.H. 42·5 µµg; M.C.H.C. 35%; white cells 2000 per c.mm; bilirubin (indirect) 3·5 mg per 100 ml.; and Schumm's test +++.

Sternal puncture on April 24 showed moderate activity of the marrow with many intermediate megaloblasts and giant stab-cells.

Gastroscopy showed very much more conspicuous anæmia of the mucosa and more extensive atrophic gastritis than on the previous occasion, and histamine-fast achlorhydria.

Treatment and progress.—The patient was kept under observation from April 23 to April 28; her reticulocytes showed no change. She was given intramuscular penicillin 400 000 units daily from April 28 to May 4. There was no reticulocyte response or increase of red cells or of Hb. On May 7 and 8 she was given vitamin B_{12} 40 µg by mouth daily; there was no response whatever in the reticulocytes, red cells, or Hb. On May 15 her marrow had typical megaloblasts, as well as the intermediate forms and giant stab-cells found previously. On May 16 and 17 she was given intramuscular vitamin B_{12} 40 µg daily; six days later her reticulocytes had increased to 20%. Ten days after the start of treatment with intramuscular vitamin B_{12} the red cells were 2,912 000 per c.mm and Hb 10·4 g per 100 ml. Nineteen days later, on June 4, the red cells were 3 340 000 per c.mm. and Hb 10·6 g per 100 ml. The patient left hospital on June 12 with red cells 3 010,000 per c.mm. Hb 11·6 g per 100 ml. and normal marrow.

As in case 3 this patient appears, both from the hæmatological and gastric examinations, to have pernicious anæmia. She differs however from case 3 in that she did respond during her early relapses to intramuscular penicillin as well as to vitamin B_{12} 80 µg by mouth. At this stage the atrophic gastritis was not so extensive as in case 3, and she had some free acid in her gastric juice. During subsequent relapses she did not respond to either intramuscular *penicillin or oral vitamin B_{12}, but did* respond to intramuscular vitamin B_{12} 80 µg. We think that this change in response was connected with an increase in both the achylia gastrica and the atrophic gastritis, which in turn was no doubt related to a decrease in the amount of intrinsic factor.

TYPE 3

Response to Folic Acid Only

Case 5 (fig 5).—A female Jaluo aged 30 with a suckling baby aged 1 month whom she continued to feed throughout her stay in hospital, entered hospital on May 19 1953 complaining of weakness, dyspnœa, and headache.

On examination she was a well nourished woman of good physique, without any enlargement of liver or spleen. Her heart, lungs, tongue, nails, teeth, and central nervous system were normal. She said that her illness started during the last two months of her pregnancy.

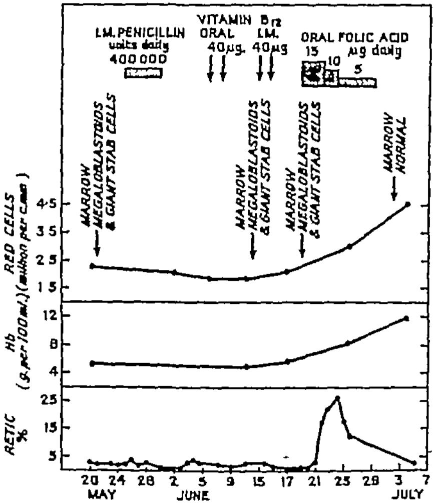

Fig 5—Type-3 anæmia showing response to folic acid only (case 5).

Blood examination on May 20 showed red cells 2,284 000 per c.mm. Hb 5·1 g per 100 ml; reticulocytes 2%; M.C.V. 70 c.µ; M.C.H. 23 µµg; M.C.H.C. 32%; white cells 3140 per c.mm.; Schumm's test negative; bilirubin (indirect) 1·5 mg per 100 ml. Kahn's test negative; no malaria; and sickling trait present.

Sternal puncture on May 20 showed active marrow with intermediate megaloblasts and giant stab-cells.

Stools contained hookworm and ascaris ova.

Gastric test showed hypochlorhydria after 1 mg of histamine.

Treatment and progress.—The patient was kept under observation from May 19 to May 25 with no treatment, during which time her reticulocytes fluctuated between 1 and 2%. She was given intramuscular penicillin 400 000 units daily from May 25 to May 30. Her reticulocytes during this time fluctuated between 0·1 and 3·5%, but there was no real response; on May 30 the red cells had decreased to 2,030 000 per c.mm. and Hb to 4·9 g. per 100 ml. From May 31 to June 6 no treatment was given, and the reticulocytes fluctuated between 0·1 and 3%. On June 6 and 7 vitamin B_{12} 40 µg was given daily by mouth. The reticulocytes showed some slight improvement but no specific response; the red cells on June 10 had decreased to 1 880 000 per c.mm. and the Hb to 4·8 g per 100 ml. The sternal marrow on June 12 gave the same picture as on May 20, with intermediate megaloblasts and giant stab-cells, and the clinical condition had deteriorated. On June 13 and 14 intramuscular vitamin B_{12} 40 µg was given, but there was no response. On June 17 the red cells were 1 906 000 per c.mm. and Hb 4·8 g per 100 ml. The marrow showed no change, and intermediate megaloblasts and giant stab-cells were still present. She was given 15 mg of oral folic acid on June 19, 20 and 21, 10 mg on June 22 and 23, and 5 mg on June 24 and 25. The reticulocytes increased to 25% six days after the start of treatment. On June 26 the red cells were 2 800 000 per c.mm. and Hb 7·5 g per 100 ml. She made an uneventful recovery and was discharged on July 4 with red cells 4 400 000 per c.mm. Hb 10 g per 100 ml., and normal marrow.

This patient appears to have a folic acid deficiency which did not respond either to penicillin or to oral or intramuscular vitamin B_{12}, again emphasising the existence of a relationship between penicillin and vitamin B_{12}. She had sickle-cell trait, grafted on to megaloblastic anæmia, which responded to the appropriate anæmia treatment.

Case 6 (fig 6)—A male Maragoli, aged 20, entered hospital on Feb 13, 1952, complaining of weakness and œdema of the legs He had been under our care in 1951 for megaloblastic anæmia On that occasion he entered with a red cell count of 850,000 per c mm, was treated with folic acid, and made a complete recovery From 1951 until the present admission he had been quite well until the onset of his present illness ten days before coming to hospital

On examination he was a well nourished man of good physique and no enlargement of liver or spleen, his nails, teeth, tongue, and nervous system were normal His heart had a hæmic murmur and was slightly enlarged, he had a slight cough, but his lungs were clear and his sputum did not contain any tubercle bacilli

Gastroscopy on Feb 21, 1952, showed very anæmic mucosa but *no* sign of atrophic gastritis There was hypochlorhydria after 1 mg of histamine

Blood examination on Feb 16 showed red cells 1,310,000 per c mm, Hb 4 g per 100 ml, M C V 89 c μ, M C H 30 4 μμg, M C H C 35%, white cells 3590 per c.mm, bilirubin (indirect) 1 3 mg per 100 ml, Schumm's test + +, Kahn's test negative, no malaria, and no sickling

Sternal puncture showed very active marrow, with many typical megaloblasts, intermediate megaloblasts, and giant stab cells

Stools contained tænia ova

Treatment and progress—The patient was kept under observation from Feb 13 to Feb 18, 1952, during which time the reticulocytes never increased beyond 0 2% From Feb 16 to Feb 22, he was given *intramuscular penicillin 400,000 units daily* His reticulocytes made no response whatever On Feb 22, his red cells had decreased to 750,000 per c.mm and Hb to 2 4 g per 100 ml On Feb 21 and 22 he was given vitamin B_{12} 40 μg by mouth daily On Feb 23, he had slight epistaxis and, as his clinical condition had considerably deteriorated, was given 500 ml of whole blood on Feb 24 Next day his red cells were 940,000 per c mm. and Hb 3 2 g per 100 ml His reticulocytes made no response and remained at 0 2% Marrow puncture on Feb 23, still showed typical megaloblasts and giant stab cells On Feb 25 and 26 he was given intramuscular vitamin B_{12} 40 μg daily, but there was no *reticulocyte response* On Feb 27, 1952, the red cells had decreased to 730,000 per c mm, Hb to 2 4 g per 100 ml, and white cells to 1300 per c.mm On March 2 the red cells were 880,000 per c mm, the marrow was still megaloblastic, and treatment with folic acid was started On the eighth day from the start of treatment the reticulocytes had increased to 34% On March 9, the red cells were 2,030,000 per c mm and there was great clinical improvement The marrow on March 8, 1952, showed complete absence of megaloblasts and giant stab cells The patient was discharged from hospital on March 26, 1952, at his own request with a red cell count of 3,220,000 per c mm and Hb 10 4 g per 100 ml

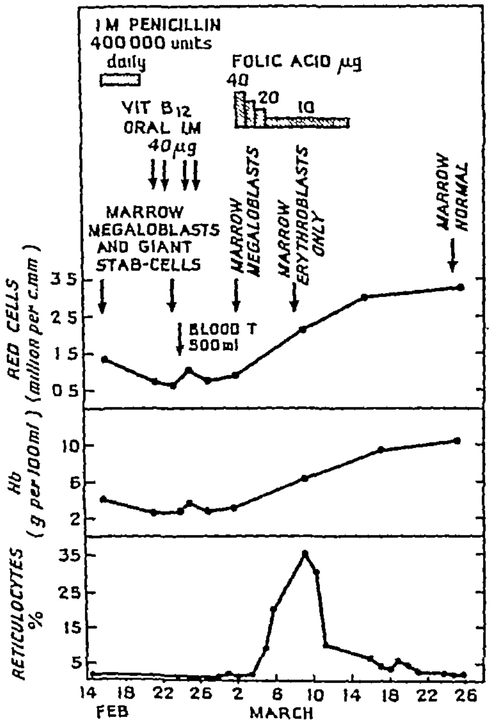

Fig 6—T anæmia showing response to folic acid only (case 6)

This is another example of folic acid deficiency, as in case 5, with no response either to penicillin or to oral or intramuscular vitamin B_{12} A 500 ml transfusion in this case was unavoidable because of the rapid and serious deterioration that took place, but it is well known that small transfusions do not influence reticulocytes or the cytological structure of the marrow

Discussion

It is evident from the above cases that the megaloblastic anæmias of Africans differ in their responses to treatment, as has been found in India and elsewhere The great majority of them respond to penicillin, and a small number do not respond to either penicillin or oral vitamin B_{12} but do respond to intramuscular vitamin B_{12}. Another group respond only to folic acid Those which respond to penicillin or to vitamin B_{12} appear to be deficient in vitamin B_{12} Those that do not respond to penicillin or to vitamin B_{12} but respond only to folic acid are deficient in this substance or its metabolites

The response of type 1 anæmias to penicillin, and the lack of response in type-3 anæmias either to penicillin or to vitamin B_{12} in any form and their subsequent response to oral folic acid, may indicate that penicillin affects the synthesis, metabolism, or absorption of vitamin B_{12} and not folic acid, at least in man

Further, it appears from the lack of response to penicillin and oral vitamin B_{12} in the type 2 anæmias, and their subsequent response to intramuscular vitamin B_{12}, that penicillin influences the biosynthesis and utilisation of intestinal vitamin B_{12}, and, like oral vitamin B_{12}, it is inactive unless intrinsic factor is present

In case 4 (type 2 anæmia) the early relapses responded to penicillin and oral vitamin B_{12}, later, with an increase in the extent of atrophic gastritis, development of complete achlorhydria, and increasing absence of intrinsic factor, no response could be obtained to either penicillin or oral B_{12}, but intramuscular B_{12} was still active

The megaloblastic anæmia accompanying infection with diphyllobothrium behaves in the same way, sometimes responding to oral vitamin B_{12} and sometimes not, and Bonsdorff (1952) suggests that the variation in response is due to changes in the amount of intrinsic factor present.

Penicillin itself contains no vitamin B_{12}, if it did, one would expect it to produce remissions in pernicious anæmia when given by injection, but from the cases described here it is apparent that it does not

We believe that penicillin produces responses in the megaloblastic anæmias of Africans by causing ecological and/or physiological changes in the flora of the gut

The intestinal flora of man and other animals synthesises a wide range of essential metabolites, such as vitamin B_{12}, riboflavine, nicotinic acid, folic acid, inositol, tocopherol, &c, and most of the available evidence *indicates that part at least of these* synthesised products can be absorbed and utilised by the host Indeed, it would be strange if the water soluble vitamins of the B group that are produced by the activities of intestinal micro organisms were not absorbed There is no doubt that vitamin K, for example, produced by the gut flora, is absorbed and made use of by the host in many kinds of animals

An enormous volume of work has been done showing that oral antibiotics increase growth-rates in many different kinds of animals over and above that produced by vitamin B_{12} alone It has also been shown that injected antibiotics cause similar acceleration of growth. Abrahams et al. (1941) found that injected penicillin was excreted in the bile into the gut. Larsen and Carpenter (1952) state that injected aureomycin is present in the fæces of pigs in amounts that vary from 42 μg to 6500 μg per g of dry fæces, and aureomycin given by mouth in amounts from 31 μg to 11 500 μg Elam et al. (1953) have shown that injected penicillin is as effective as oral penicillin in promoting growth It therefore seems that the fæcal concentration and the effectiveness of oral and injected antibiotics are similar and both are sufficient to produce changes in the floral equilibrium accompanied by alterations in synthesis and utilisation of essential metabolites Cuthbertson (1952) has shown that oral penicillin decreases the need for vitamin B_{12} in chicks, and it is not unlikely that when injected it would do the same.

Coates (1953) has suggested that the increased growth may be due to the suppression of some unidentifiable infection which the antibiotic clears. The megaloblastic anæmias with which we have dealt have never had any known pathological infection and the response of these anæmias to penicillin is exactly the same as we get with liver vitamin B_{12}, and folic acid and so far as we are aware these hæmatinics are not thought to produce their effects by suppressing infections but by supplying some hæmopoietic deficiency

The fact that antibiotics often produce resistant and dependent strains of organisms is evidence that profound physiological changes have taken place which may not be reflected by any quantitative changes in the flora. Microbiological evidence indicates that even small changes in the flora in one group of organisms, may be followed by profound alterations in the ecological balance of the whole gut

The view that antibiotics produce their effects by altering the floral milieu of the gut is also supported by the fact that a number of substances which differ from each other and have in common only their bacteriostatic or bactericidal properties—e.g sulphonamides sodium arsanilate cation-exchange resins, and some detergents—can hasten the rate of growth in animals. The common denominator of all these substances is their effect on bacteria, on the medium in which they exist, or on the metabolism of the host (Card 1951)

The biosynthesis and availability of vitamins differ in the different animal species, and the presence of any particular vitamin in the intestinal tract of one species is not evidence of its presence or availability in another Further the responses of the different animal species to antibiotic supplements is not the same, and it is therefore impossible to assume that because an antibiotic has a given effect in one species it will have the same effect in a different species.

The work on germ free chicks (Reyniers et al 1950) was initially interpreted as evidence that changes in intestinal flora were not a factor in the promotion of growth that followed the giving of antibiotics to animals. The work of Luckey (1952) seems to indicate that in the chick at least intestinal flora may retard growth since sterile chicks grow better than non-sterile, and non-sterile ones given antibiotics better than non-sterile ones without antibiotics. Liver damage in rats on a necrogenic diet affects the left lobe and can be prevented by antibiotics; the portal supply to this lobe is from the lower gut, a locus of bacterial activity, and antibiotics may produce their effects in such cases by suppressing flora producing toxins.

Variations in diet are also known to produce great changes in the gut flora dextrin, for example encourages a denser flora than sucrose and rancid fats have a profound effect on the ecology and metabolism of intestinal micro-organisms and have been suggested as a factor in the production of the sprue syndrome The prevalence of megaloblastic anæmia in primitive communities may be connected with a diet predominantly high in bulky carbohydrates and low in first-class protein, which may encourage a flora inimical to the production of essential metabolites.

Antibiotics may bring about their effects by any or all of the following mechanisms:

(1) Ecological changes in the gut flora which lead to the destruction of antagonists or of competitors interfering with synthesis, absorption or utilisation of hæmopoietic factors, or to an increase in those types concerned with the synthesis of vitamin B_{12} or of other hæmopoietic substances.

(2) Interference with bacterial metabolism leading to release or to increase in availability of factors essential either to the host or to other bacteria.

(3) Sparing action of the antibiotic on vitamin B_{12} or on proteins, or effects on amino-acid metabolism or methyl group synthesis.

(4) Destruction of toxins inhibiting hæmopoiesis, or growth of synthesising flora.

(5) Presence in the antibiotic of hitherto unknown hæmopoietic factors.

(6) Changes in metabolism of the host, leading to increased utilisation or absorption of essential factors.

Summary

The megaloblastic anæmias of Africans are of three well defined types, which can be classified according to their response to treatment

Type 1 responds to penicillin and all known hæmatinics

Type 2 does not respond to penicillin or to oral vitamin B_{12} but does respond to intramuscular vitamin B_{12}

Type 3 responds only to folic acid

On the basis of the results described it is suggested that penicillin is in some way connected with the intestinal production of vitamin B_{12}

PREVENTION OF FERTILISATION BY A HYALURONIDASE INHIBITOR

A. S Parkes
Sc D Camb. F R.S
From the National Institute for Medical Research, Mill Hill London

The mass of cumulus cells which surrounds the newly ovulated egg in certain mammals, notably the rabbit, was observed to disintegrate rapidly in the presence of spermatozoal suspensions (Yamane 1930 Pincus and Enzmann 1935) The responsible agent was later identified as hyaluronidase the already known 'spreading factor of testis extracts (McClean and Rowlands 1942) These workers all held the view that the adherent cumulus cells must be removed before a spermatozoon could approach and penetrate the zona pellucida, the implication being that a bulk supply of hyaluronidase was required at the site of fertilisation This idea was of interest in that it provided a reason for the production of such vast numbers of spermatozoa by the male mammal and it suggested that human cases of infertility associated with low sperm counts might be assisted by the provision of additional hyaluronidase Some experimental evidence in support of the idea was obtained (Rowlands 1944), but in the course of time several serious objections appeared. In particular, further work (Austin 1948) confirmed earlier observations that usually very few spermatozoa are present at the site of fertilisation, and that fertilisation normally takes place in the rat while the egg is surrounded by cumulus cells (Austin and Smiles 1948) and in the rabbit while the corona radiata is still present (Swyer 1947a) Moreover, renewed attempts to potentiate small numbers of spermatozoa by the simultaneous insemination of additional hyaluronidase gave negative results (Chang 1950)

It has thus become difficult to accept the idea that a bulk supply of hyaluronidase, coming from a mass of spermatozoa, is an essential prerequisite of fertilisation Nevertheless, as Austin has pointed out, a possibility, perhaps a probability, remains that the approach of a spermatozoon to the zona pellucida is assisted by its own individual supply of the enzyme, which may thus have some role in fertilisation in some species It was rational, therefore, to investigate the effect of decreasing the effective availability of the enzyme, by adding either hyaluronic acid complexes or hyaluronidase inhibitors to the semen before insemination, and the addition of hyaluronic acid derivatives (Pincus, Pirie, and Chang 1948) or phosphorylated hesperidin (Chang and Pincus 1953) has been reported to lower the fertilisation-rate in rabbits It should be noted, however, that Chang and Pincus did not get complete inhibition even when the inhibitor was present at a concentration of 1% In view of this, the earlier reports of decreased fertility in rats (Martin and Beiler 1952) and mice (Sieve 1952) following systemic administration of phosphorylated hesperidin, can be regarded as only suggestive, while the startling claim of clinical effectiveness (Sieve 1952) cannot be accepted without confirmation

Quite apart from any question of application to contraception, the work on the effect of inhibitors is a means of investigating the rôle of hyaluronidase in fertilisation, and perhaps that of other enzymes since the hyaluronidase inhibitors commonly used are far from specific I report here the results of an extensive series of experiments on rabbits carried out with a new and powerful inhibitor 'Rehibin'—tri gentisic acid, Compound 21P (Hahn and Frank 1953)—prepared by the research laboratory of AB Ferrosan

Investigations

TECHNIQUE

Rabbit semen was obtained by the use of an artificial vagina (Macirone and Walton 1938) All the inseminations involved in any one experiment, usually 3-6, were made with aliquot parts of a large composite batch The dose for one insemination consisted of 0 25 ml semen plus 0 75 ml Baker diluent (or in special cases 0 75 ml of a source of additional hyaluronidase), plus 1 0 ml Baker diluent containing the required amount of inhibitor The total volume of 2 0 ml was found to be a convenient amount for insemination The female rabbits were given 50 I U chorionic gonadotrophin immediately before insemination to cause ovulation, and they were killed approximately forty eight hours later, by which time fertilised eggs had reached the morula stage

The rehibin was somewhat insoluble in the diluent and the addition of a small amount of alkali (NaOH) followed by neutralisation, was necessary Subsequent experience showed that the water-soluble sulphonic acid polymers, described by Rogers and Spensley (1953), are about equally effective in inhibiting fertilisation and are much more [illegible]venient to work with

ANTI-FERTILISATION EFFECT OF REHIBIN

In preliminary experiments, a wide range of doses of rehibin (25 0–0 1 mg) was tried and the mixture was allowed to stand for one hour before insemination Results indicated that about 1 0 mg was the critical amount, and, in all, only 7 eggs were fertilised out of 45 eggs recovered from 8 rabbits following insemination with semen containing 1 mg of rehibin (table I) This result, obtained with rehibin at a concentration of 0 05%, appears to be similar to that obtained by Pincus and Chang with phosphorylated hesperidin at a concentration twenty times greater It is not evident, however, from my work or from theirs, whether concentration or absolute amount of the inhibitor is the operative factor It may be noted that 25 mg of rehibin in 2 ml of diluted semen had no obvious spermicidal action even after the mixture had been allowed to stand for one hour

RELATION BETWEEN DOSE AND EFFECT

An attempt was then made to determine more accurately the relation between dose and effect over the critical range For this purpose the technique was altered slightly in that the mixture was inseminated immediately without being allowed to stand at room temperature In this experiment three replications were made of a series in which doses of 0 5 mg , 1 0 mg , and 2 0 mg were each used on one rabbit Allowing for the fact that the mixed batches of semen used in each replication may well have varied in hyaluronidase content, the results are remarkably uniform, and indicate a relation between dose and response unexpectedly sharp for this kind of multiple reaction The other interesting feature of these results is that comparison of tables I and II suggests that allowing the mixture to stand before insemination has little effect on the result, so that the action of rehibin, whatever it may be, appears to be rapid.

TABLE I—EFFECT OF ADDING DIFFERENT AMOUNTS OF REHIBIN TO A CONSTANT AMOUNT OF SEMEN (0 25 ML.) (SEE TEXT FOR DETAILS OF TECHNIQUE)

Amount of rehibin added (mg)	No of rabbits	Total no of eggs	Number fertilised
25	1	5	0
10	3	26	0
5	1	5	0
4	2	13	0
1	8	45	7
0 5	1	3	3
0 25	1	7	7
0 1	1	4	4

MECHANISM OF THE REHIBIN EFFECT

An experiment was then carried out in which three different amounts of semen were associated with two different amounts of rehibin, the total volume of the mixture for insemination being kept to 2 0 ml (table III) It will be seen that increasing the amount of semen above 0 25 ml overcomes the effect of 1 0 mg of rehibin, but that the addition of large excess of rehibin in turn "neutralises" even 1 0 ml of semen It seems possible, therefore, in a rough way, to titrate semen against the

TABLE II—DOSE EFFECT RELATION BETWEEN AMOUNT OF REHIBIN ADDED TO 0 25 ML SEMEN AND THE NUMBER OF EGGS FERTILISED

0·5	8/8	0/6
1·0	6 6	0/7

Figures indicate proportion of eggs fertilised One rabbit for each combination.

inhibitor, within a constant total volume of mixture. This result provided further evidence that the effect of rehibin was *more than a non-specific spermicidal action* Further experiments were therefore undertaken in which additional hyaluronidase was added to a mixture containing the usual amount of semen (0 25 ml) and a fully effective dose of rehibin (2·0 mg)

The first source of additional hyaluronidase tried was a freeze-dried extract of bull testis which unfortunately proved to be toxic to the spermatozoa. It was then decided to use rabbit semen without living spermatozoa, as the source of additional hyaluronidase No positive results were obtained with a seven year old freeze dried mixture. Fresh semen in which the spermatozoa had been killed by freezing and thawing was then used, it being expected that the spermatozoa killed by this method would liberate rapidly the store of hyaluronidase, which seeps out of the living spermatozoa rather slowly (Swyer 1947b) Later seminal plasma obtained from frozen and thawed semen by centrifugation was used as the source of hyaluronidase.

In these experiments, therefore, the mixture inseminated consisted of 0 25 ml semen, 0 75 ml. killed semen or seminal plasma, and 1·00 ml. Baker solution containing 2 0 mg rehibin. Table II suggests that this amount of additional seminal hyaluronidase should overcome the effects of 2 mg rehibin but without much margin In practice, 38 eggs were fertilised out of 40 obtained from 7 rabbits inseminated with the mixture This result gave further support to the idea that the effect of rehibin depends on the inactivation of spermatozoal hyaluronidase or other enzyme playing a part in fertilisation.

PRIOR INSEMINATION OF REHIBIN

9 experiments in which rehibin in amounts up to 10 mg., was inseminated one hour before the insemination f semen or normal mating gave no significant positive esults.

SYSTEMIC ADMINISTRATION OF REHIBIN

In view of earlier claims to have inhibited fertilisation by the oral administration of hyaluronidase inhibitors, a arge number of experiments were made giving rehibin by mouth. Rabbits quite readily drank water to which he substance had been added and up to 250 mg per day could be administered by this method. In these xperiments a number of unfertilised eggs were recovered following *insemination or mating of animals so treated,* but no reproducible positive results were obtained. This was perhaps not surprising in view of the doubt as to whether such a substance would be absorbed from the gut—a doubt increased by the apparent failure to secure absorption following subcutaneous or intraperitoneal injection.

Mechanism of Effect of Rehibin

These experiments show that rehibin inhibits fertilisation when added, in vitro to rabbit semen before insemination at the rate of about 5 mg per ml. They also suggest that the effect is not that of a non-specific spermicide and that it depends on the inhibition of hyaluronidase At first sight this result, like the less quantitative one obtained with phosphorylated hesperidin by Pincus and Chang, strongly supports the idea that hyaluronidase plays an essential rôle in fertilisation. For reasons given in the introduction, this rôle is almost certainly not the mass dissolution of the cumulus adhering to the egg after ovulation but it could be that of assisting the individual spermatozoon to penetrate between the residual cells. The results of phase-contrast microscopy of eggs whose non fertilisation was associated with the use of rehibin were mainly concordant with this view, in most instances no spermatozoa were observed nearer to the egg than the inner layers of the residual cumulus and signs of activation (discharge of second polar body formation of female pronucleus) were not observed in eggs found to be undivided at a time when segmentation should have been well advanced Sometimes, however especially where the dosage of rehibin had been marginal, *spermatozoa were seen to be embedded in the zona or* even to have got through into the perivitelline space in eggs showing neither segmentation nor even activation The exact significance of this observation cannot be assessed without detailed comparison with control material, but it may be that the spermatozoon is incapacitated by rehibin in some way other than or additional to, the ' neutralisation " of hyaluronidase

Summary

'Rehibin,' a highly active inhibitor of hyaluronidase prevents fertilisation when added in vitro to rabbit semen before insemination, at the rate of about 5 mg per ml of neat semen

Rehibin has no ordinary spermicidal action in the amounts used and the effect on fertilisation probably depends, at least in part, on its capacity to inhibit hyaluronidase. But this may not be the whole explanation

Attempts to inhibit fertilisation by the administration of large amounts of rehibin orally or by injection gave no reproducible positive results, but absorption of this large molecule material may well have been negligible.

My thanks are due to Miss H. M. Bruce for assistance with the work on systemic administration, to Dr Audrey U Smith who carried out the microscopical examinations of the eggs to Dr H. J Rogers and Dr P Spensley for much helpful information, and to Dr G I M Swyer who first called my attention to rehibin. The technical procedures involved were mainly carried out by my assistant Mr F Crisp. The rehibin was kindly supplied by Mr E M. Bavin of Messrs. Smith & Nephew Research.

We owe the Flying Saucers to airmen, technicians and the like all members of communities that pride themselves on their realism and common sense. It is hard luck on these fellows, of course. Just as they are beginning to feel that through science technics and know how they are masters of life, it seems that little blue monsters arrive from outer space to spy on them, behaving in a fashion that apparently makes them feel inferior and *somehow guilty* if we leave all the old nonsense behind, run as fast as we can away from gods and devils, saints and witches, we only arrive at the place where three headed Martians are watching us. In short the old wild dreams of the Unconscious break through. Moved by feelings we refuse to recognise we project uncanny and sinister images against the very sky itself What secret bitterness is in the Cup to which these are the Saucers? —J B. PRIESTLEY *New Statesman* Dec. 5, 1953, p 712.

HIRSCHSPRUNG'S DISEASE WITH ASSOCIATED INTESTINAL HÆMORRHAGE

R E Horton

CONSULTANT SURGEON, UNITED BRISTOL HOSPITALS , LECTURER IN SURGERY IN THE UNIVERSITY OF BRISTOL

Bernard Laurance
M.B Lond , M R C.P , D C.H
SENIOR REGISTRAR, ROYAL HOSPITAL FOR SICK CHILDREN, BRISTOL , TUTOR IN CHILD HEALTH IN THE UNIVERSITY OF BRISTOL

Before 1948 the terms " megacolon " and " Hirschsprung's disease " were used synonomously and applied to all cases of segmental or total dilatation of the large intestine in which there was no demonstrable organic lesion These conditions are now separated into two distinct clinical entities, largely as the result of the work of Ehrenpreis (1946), Swenson and Bill (1948), and Swenson, Rheinlander, and Diamond (1949) in America, and, in this country, of Bodian, Stephens, and Ward (1949, 1950), who added an important pathological study to their clinical and radiological findings

Pathology

By " idiopathic megacolon " is meant total dilatation of the large intestine down to the anal sphincter This is in contrast to " Hirschsprung's disease," in which the dilatation is confined to the proximal portion of the large intestine Distally, there is a narrow segment of variable length which acts as a functional obstruction In more than 90% of cases this narrow segment is confined to the rectum and part or all of the sigmoid colon Occasionally the dilated portion, besides involving the whole colon, extends for a variable distance along the small intestine Rarely the narrowed segment is in the middle of the large intestine, in which case the segment proximal to it is dilated, and that distal to it is normal

In Hirschsprung's disease Bodian et al (1949) have amplified the work of Zuelzer and Wilson (1948) and have shown that in the narrowed segment there is a total absence of Auerbach's and Meissner's plexuses, though nerve fibrils (thought to be sympathetic in origin) and interstitial cells are present They concluded that this absence of parasympathetic ganglia was congenital The aganglionic segment cannot dilate and therefore acts as an organic obstruction In idiopathic megacolon the parasympathetic and sympathetic ganglia are normal

Clinical Picture

Hirschsprung's disease is genetically determined. In a patient known to have this condition the chances that a brother is similarly affected are about 1 in 5, whereas the chances that a sister is affected are much smaller (Bodian et al 1951)

The passage of meconium may be delayed for several days, and constipation is a feature from the beginning Occasionally vomiting and abdominal distension shortly after birth lead to the diagnosis of obstruction More often the gaseous abdominal distension is of less acute onset Attacks of subacute obstruction, accompanied by stools that are hard and pellety or soft and ribbon like, are relieved by the passage of flatus in bouts of explosive foul diarrhœa As the disease progresses, the abdomen becomes greatly distended, and visible peristalsis may be seen The effect on general health is variabl Growth is usually inhibited, and in some cases wasting is very severe Because of the obstruction occasioned by the aganglionic segment the rectum distal to the obstruction contains little fæces when examined digitally and may be empty Sigmoidoscopy can be performed and the narrow segment negotiated, but at its proximal end an impenetrable fæcal barrier is reached,

Idiopathic megacolon is a condition in which, although constipation is trouble some from an early age, the passage of meconium is not delayed The constipation yields more readily to aperients, and on examination fæcal masses may be felt in the distended abdomen The rectum shares in the general colonic loading and on digital examination is always full

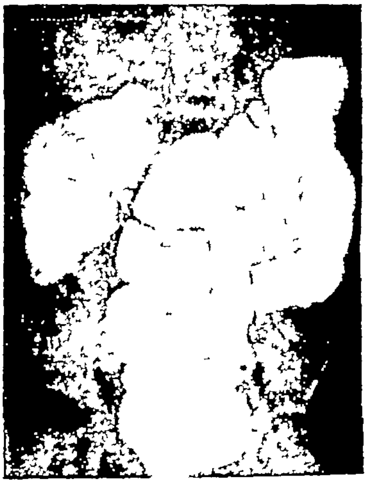

Fig 1—Barium enema in megacolon.

The narrowed segment rendered visible after a barium enema is pathognomonic of Hirschsprung's disease, whereas in idiopathic megacolon the colon and rectum are distended to the anal sphincter (fig 1)

Treatment

Swenson and Bill (1948) were the first surgeons to publish results of rectosigmoidectomy, now extensively practised for the relief of Hirschsprung's disease At first the operation was done in three stages a preliminary transverse colostomy was made and the colon cleared with enemata and washouts , at a second operation the aganglionic segment was removed , and finally, at a third operation, the colostomy was closed Subsequent experience has shown that with careful colonic preparation the operation may be safely completed in a single stage as in the case reported here

Case-Report

A B , aged 2½, is the only child of healthy parents He was born on Dec 15, 1949, by normal delivery after an

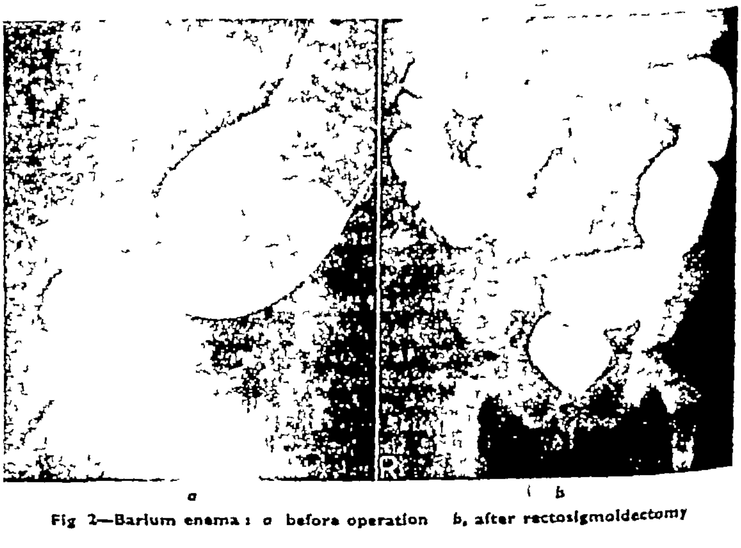

Fig 2—Barium enema : a before operation b, after rectosigmoidectomy

uneventful 30 weeks gestation. At birth he weighed 6½ lb During the neonatal period he had some 'vomiting and constipation,' but no further details are available

History and Investigations

During the first 2 months of life he was seen by Dr L W Hale (to whom we are most grateful for the detailed early history) because of this constipation A barium enema showed a large colon, which was not, however, pathognomonic of Hirschsprung's disease With symptomatic treatment the bowel action became regular The bouts of constipation recurred on several subsequent occasions and necessitated admission to hospital for correction.

In May, 1951 when 17 months old he was admitted because of vomiting pallor abdominal distension, and the passage of blood per rectum. The hæmoglobin was 24% (3·5 g per 100 ml) and the red-cell count 2 100 000 per c.mm The platelets and clotting time were normal. A blood transfusion was given and the constipation again rectified with enemata. Subsequently the fæces persistently gave a strongly positive test for occult blood even when the boy was having voluntary bowel function aided by a combination of liquid paraffin and a high residue diet A barium enema repeated at this time showed megacolon.

The boy was taken home by his parents against advice, but was readmitted 8 or 10 weeks later again with a loaded colon and a hæmoglobin of 38% (5·6 g per 100 ml) His bowel action was corrected and his hæmoglobin raised to 86% (12·7 g per 100 ml) with blood transfusion. Subsequent treatment with large doses of ferrous sulphate did not maintain this level and in a month it had dropped to 75% tests for occult blood in the stools being positive

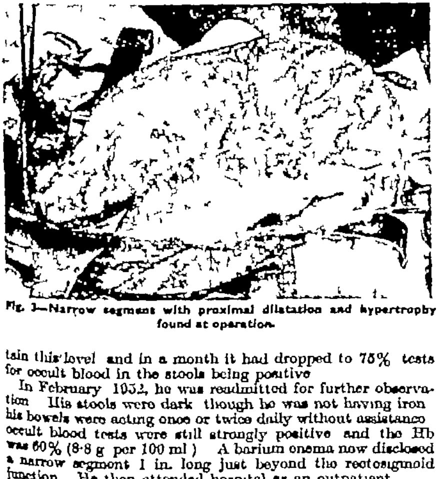

Fig. 3—Narrow segment with proximal dilatation and hypertrophy found at operation.

In February 1952, he was readmitted for further observation His stools were dark though he was not having iron his bowels were acting once or twice daily without assistance occult blood tests were still strongly positive and the Hb was 60% (8·8 g per 100 ml) A barium enema now disclosed a narrow segment 1 in. long just beyond the rectosigmoid junction. He then attended hospital as an outpatient.

In March, 1952, he was readmitted as an abdominal emergency with vomiting constipation, and pyrexia. The acute symptoms rapidly subsided, and investigation showed that the hæmoglobin was 62%, and tests for occult blood in the stools were still positive

On June 20 1952 he was admitted to the Bristol Royal Hospital for Sick Children. He was a well nourished though pale boy weighing 25 lb. 3 oz. (average for age 20 lb) and 33½ in. tall (average for age 33½ in.) Abnormal physical signs were confined to the alimentary system. The abdomen was distended and the colon palpable throughout most of its length A blood-count showed Hb 52% (7·7 g per 100 ml.) white cells 8400 per c.mm. (neutrophils 4200 per c.mm.) and platelets 313 000 per c.mm Tests for occult blood in the stools were negative

On July 12, a barium enema showed the colon to be considerably dilated proximal to a narrow segment at the rectosigmoid junction (fig 2a)

Immediately after admission bowel action was irregular with constipated and occasionally bloodstained stools. Subsequently however all bleeding ceased and further tests for occult blood in the stools were negative Peristalsis was occasionally visible The anæmia was corrected with a blood transfusion, and thereafter the boy was given an oral iron preparation.

On July 18 at sigmoidoscopy the instrument could not be passed beyond the recto-sigmoid junction because of fæcal masses. No cause for rectal bleeding was seen The diagnosis of Hirschsprung's disease being firmly established the patient was prepared for operation

Preparation for Operation

Daily olive oil enemata and later rectal washouts for about 8 weeks reduced the distension of the colon. On Oct. 13 1952 the sigmoidoscopy was repeated under general anæsthesia, and a rectal tube was passed into the colon and fixed in place with strapping Colon washouts were done thrice daily until the rectosigmoidectomy was performed 3 days later

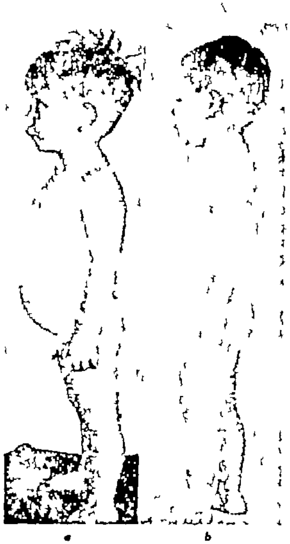

Fig 4—Appearance of abdomen: a before operation; b after rectosigmoidectomy

Rectosigmoidectomy

At operation the great hypertrophy of the colon proximal to the obstruction and the narrow segment were seen at once (fig 3) The operation was done by the 'pull through' technique using two layers of interrupted sutures for the anastomosis. The colon was empty and the success of the preoperative bowel preparation without resort to colostomy was apparent. The resection extended distally to just above the anal sphincters and proximally for 5 in. above the narrow segment

Result

Postoperative course was uneventful. There was no interference with bladder function, and the urethral catheter was removed on the morning after the operation. The bowels were opened daily when he was discharged from hospital and there was no interference with continence He was readmitted 5 months later when he weighed 30½ lb His bowels were now acting normally he had no abdominal distension (fig. 4), and a barium enema showed a normal colon (fig 2b)

Pathology

The muscle wall of the colon and rectum varied in thickness but in one area it narrowed and it was here that no ganglion cells could be seen in either the submucous or the myenteric plexus. In the thickened part of the muscle however ganglion cells were present normally and nerve-fibres were also seen There was no mucosal ulceration

Discussion

Because intestinal hæmorrhage is so unusual in Hirschsprung's disease, this case is worthy of comment.

Until the age of 17 months the symptoms and signs were compatible with Hirschsprung's disease. After this the rectal hæmorrhage was severe enough to reduce the hæmoglobin to 24% (3·5 g per 100 ml) and 38% (5·6 g per 100 ml) on two occasions, suggesting the alternative diagnosis of neoplasm and of angioma of the bowel A barium enema did not disclose any cause for the severe rectal bleeding

Although intestinal bleeding is rare, anæmia is often found in Hirschsprung's disease as a result of chronic ill health and malnutrition Of the 39 children reported by Bodian et al (1949) 4 were moderately anæmic and in 2 others the hæmoglobin dropped to 35% and occult blood was present in the fæces Stammers and Rains (1952) reported a lad, aged 18, in whom the hæmoglobin fell to a similar level (36%), but this was attributed to malnutrition, he was not known to have any frank or occult bleeding from the bowel at any time (Stammers, personal communication). We assume that the severe bleeding in our patient was due to stercoral ulceration secondary to fæcal impaction

Compared to simple idiopathic megacolon with rectal stasis, the incidence of Hirschsprung's disease is small The records have been reviewed at the Bristol Royal Hospital for Sick Children of all patients in 1947–52 diagnosed as having either Hirschsprung's disease or idiopathic megacolon, and where doubt has existed about the correctness of the diagnosis the patient has been re examined, if necessary by barium enema Of the total of 42 patients 35 (83 4%) had simple idiopathic megacolon and 7 (16 6%) had true Hirschsprung's disease

Summary

A case of Hirschsprung's disease is described in which intestinal bleeding (an unusual phenomenon) was a prominent clinical feature The results of rectosigmoidectomy were satisfactory

We are indebted to Prof A V Neale, who referred the case to one of us, for his interest in this paper Dr J M Sheach carried out the radiological investigations, and the department of clinical photography of the University of Bristol provided the photographs

ACUTE HEPATIC NECROSIS

COMA TREATED WITH SODIUM GLUTAMATE

C E WOODROW
M B Camb, M R C.P
CONSULTANT PHYSICIAN

KENNETH FROOME
M B Lond.
CONSULTANT PATHOLOGIST

I H LAWRENCE
M B Edin
MEDICAL REGISTRAR

SCARBOROUGH GROUP OF HOSPITALS, YORKSHIRE

GLUTAMIC acid has been used by Walshe (1953) to treat coma due to subacute or chronic liver injury We have recently had a case of acute hepatitis, probably of virus origin, associated with cerebral symptoms, which has responded to such therapy Latner (1950) has reported 5 cases of "acute yellow atrophy" in which the normal modern supportive therapy led to recovery from coma, but no other such cases have been published

Case-record

Miss A, a university student aged 22, had had appendicitis at the [illegible] of 4 There was no history of transfusions or of taking drugs. A possible source of infection was from penicillin injections for boils some three months ago A month before the present illness she had been travelling abroad in Norway, Holland, and elsewhere The Friedman test was negative For two or three weeks before admission she had not been feeling well, had anorexia, and was mildly depressed There was nothing relevant in the family history

Sept 24—Onset of vomiting Took fluids well and was mentally normal

Sept 27—Vomiting persisting and anorexia getting worse Temperature 99°F

Sept 28—Not taking fluids well, and developing a mild icteric tinge

Sept 29—Refused to take anything by mouth and appeared on occasions to lapse into coma Seen by one of us (C E W) and admitted to Scarborough Hospital Then stuporose but attempted when left alone to get out of bed and walk about. Temperature 100–101°F, pulse rate 100 per min Blood pressure 130/85 mm Hg Slight clinical jaundice Respiratory and cardiovascular systems normal No apparent abdominal tenderness No definite liver enlargement and spleen not felt Extensor plantar responses were found during the period of coma, but there were no other abnormal neurological signs

Sept 30—Little change, still mild jaundice, but maniacal symptoms developed, with attacks of screaming when feeding or venepuncture was attempted, followed by coma and stupor Had to be controlled periodically with intramuscular paraldehyde 10 ml

Oct 1—Jaundice deepening and cerebral condition the same Treatment with 10% intravenous glucose and vitamin supplements intravenously and intramuscularly was started Crystalline vitamin B_{12} (cyanocobalamin) 200 µg was given

Oct 2—Both jaundice and coma were deep and there were periods of considerable restlessness Bile present in the urine but no urobilinogen detected. Sodium glutamate therapy was started, and in the following twenty four hours 60 g was given in three doses of 20 g intravenously in 1 5 litres of 10% glucose solution There was no dramatic improvement, but during the absorption of the sodium glutamate the patient was definitely more restless and less comatose She was gravely ill, and the immediate prognosis seemed very poor The lung bases were clear, and there was no œdema Aureomycin 250 mg six hourly was started, and continued via a Ryle's tube until it could be taken orally

Oct 3—Jaundice still deeper, and coma persisting Two doses of sodium glutamate 20 g were given intravenously in 500 ml of 10% glucose at 10 45 A M and 5 30 P M. Two hours after the first dose the patient was slightly less jaundiced but noisy and very restless No urobilinogen Bilirubin present in urine

Oct 4—Less deeply comatose, and jaundice appeared lighter All treatment continued and sodium glutamate 20 g given intravenously Still no clinical fluid retention in the tissues Again there was an increase in restlessness during the absorption of the sodium glutamate

Oct 5—Patient regained consciousness and was soon able to take oral feeds Intravenous drip was discontinued, and glutamic acid 5 g in amorphous powder suspended in 4 oz. of milk was given six hourly, at first by Ryle's tube, but soon by mouth. The mental condition rapidly improved, and in a few hours she was mentally normal. During the coma the fluid balance was well maintained.

Further Progress—From this date the patient has remained mentally clear On Oct 19 jaundice was still present but was clearing Oral glutamic acid 20 g daily in divided doses was continued until Oct 15 Since it was stopped there has been no deterioration in the mental state, which has remained normal. All vitamin supplements and aureomycin therapy are continuing Appetite is good, and apart from its taste the glutamic acid has been well tolerated. There has been no evidence of renal tubular necrosis during the illness.

Pathological Investigations—On admission on Sept 29 the urine showed traces of bilirubin, but urobilinogen was absent A blood-count showed Hb 120%, red cells 5,900,000 per c.mm., colour index 1, leucocytes 7000 per c mm (neutrophils 56%, monocytes 2%, lymphocytes 42%) A stained film showed no significant abnormality Serum agglutination reactions for salmonella organisms were negative. The serum alkaline phosphatase level was 9·6 units per 100 ml., and the thymol turbidity 14 units per 100 ml. The total serum protein level was 7·6 g. (albumin 3·9% globulin 3·7%) per 100 ml. The serum bilirubin level was 12·5 mg per 100 ml The pattern of the electrophoretic filter paper strip (Flynn and de Mayo 1951) showed a qualitative increase in the gamma-globulin fraction. No leptospira were seen in the urine and serum agglutination tests for the leptospiral group were negative.

On Oct. 5 the liver function tests showed no change but the serum bilirubin was reduced to 10 mg per 100 ml and the blood urea was 20 mg per 100 ml. Urobilinogen was found on this day for the first time and has been present since.

Follow up.—On Oct. 21 the *patient was transferred to a* nursing home in Leeds under Dr I Macpherson, who on Nov 24 sent the following report for which we are indebted to him: At present the patient is only slightly jaundiced, and there has been no bile in the urine for at least a week She has received a high protein low fat diet with methionine 1 g t.d.s. vitamins B and C, and Castlan 2 drachms t.d.s. Liver function tests on Nov 18 showed serum alkaline phosphatase, 7 units per 100 ml. serum gold sol no 5 and serum thymol turbidity 10 units per 100 ml It is therefore clear that liver function is still considerably impaired.

Comment

Although it cannot be categorically stated that the sodium glutamate therapy was responsible for recovery in this case we feel that without such treatment the prognosis would have been extremely poor and the result obtained warrants its further trial in hepatic coma Walshe (1953) has proved its value in subacute and chronic liver disease with cerebral manifestations, but we have not been able to trace any reference to its trial in acute hepatic necrosis. Its mode of action is unknown but it does seem to be of value as a supportive measure until the virus invasion can be dealt with by the natural defence mechanisms. The fault in hepatic coma may be a deficiency of glutamic acid (*Lancet* 1953) a substance necessary for removing the toxic ammonium radicle produced as a normal cerebral metabolite which combines with glutamic acid to form the amide glutamine Our dosage of sodium glutamate was far higher than that recommended by Walshe who warns of the danger of water retention due to sodium intoxication We found no evidence of this despite the dosage used, and serum sodium estimations at the end of the intravenous therapy gave a figure just below normal The only effect apparent clinically was to increase restlessness Salivation flushing, and vomiting were not noted at all Our normal procedure was to administer sodium glutamate 20 g in 500 c.cm of 10% glucose allowing three or four hours for the infusion No adverse effects were noted, even when on one occasion by mistake the intravenous dose was administered far too quickly

Although evidence of the value of aureomycin in virus hepatitis is conflicting in view of the severity of the present case we felt that its use was justified especially as recent work has shown that the mortality of experimentally induced acute hepatic necrosis in rats is significantly reduced by this antibiotic The effect may be a direct nutritional one on the liver

We are indebted to Dr J C Broom for undertaking the leptospiral agglutination tests; to Dr I. Macpherson, the Leeds Hospitals, and British Drug Houses Ltd for supplies of sodium glutamate and glutamic acid; to Dr J P Whitehead for help with the pathological investigations and to Mr F B Trenholme for technical assistance.

SENIOR REGISTRAR, DEPARTMENT OF PHYSICAL MEDICINE

ST THOMAS'S HOSPITAL, LONDON

THE association of bronchial neoplasms with lesions of the central and peripheral nervous system is well known The presence of severe muscle weakness in a case of bronchial neoplasm seen in this hospital in 1951 and its almost immediate disappearance after removal of the tumour, suggested that such neoplasms might give rise to an unusual form of peripheral neuropathy possibly similar to myasthenia gravis When unequivocal features of myasthenia and an abnormal response to succinylcholine were seen in another case of bronchial neoplasm the abnormality of neuromuscular transmission was investigated fully

Case record

A carpenter aged 47 was admitted to St. *Thomas's Hospital* in July 1953, complaining of progressive muscle weakness. He stated that he was well until February 1953, apart from a fall off a ladder in November 1952 as a result of which he suffered a brief period of unconsciousness and a trivial injury to his elbow In February 1953 he noticed that after lunch his legs, from the thigh down became progressively weaker on walking Thus, while he was normal on rising in the mornings, by the evenings he found it difficult to stand. Three weeks after the onset of this weakness he was obliged to give up work Later his arms also became involved, and he found that his head felt heavy while watching television, and he had to support it. At this time he also had transient diplopia on looking to the right and transient difficulty in swallowing towards the end of a meal. There was no nasal *regurgitation. No ptosis or speech defect was complained of* and he had not noticed any abnormality of consciousness memory sensation, or micturition. He smoked 20 cigarettes a day and enjoyed his daily pint of beer

CLINICAL EXAMINATION

He was an alert healthy looking man weighing 60·7 kg His speech was somewhat thick and slurred but he stated that there had been no recent change in it The fundi and cranial nerves were normal. His muscle power was generally weaker than his muscle bulk would suggest, especially the muscles of the shoulder girdle, hip girdle, trunk, and anterior compartments of the legs. Their tone was normal The arm reflexes were diminished The abdominal reflexes were absent and the left ankle jerk was diminished. The plantar reflexes were both flexor All forms of sensation were normal. No excessive fatigability of muscles could be demonstrated The only abnormality observed in the chest was a diminished percussion note on the anterior aspect of the right apex. All other systems were normal on clinical examination.

INVESTIGATIONS

Radiography of the chest showed collapse of the right upper lobe with enlarged right upper hilar and paratracheal glands.

Bronchoscopy (Mr G Kent Harrison) showed a new growth presenting through the posterior wall of the lowest inch of the trachea and involving the right main bronchus.

For this operation the patient was anæsthetised with thiopentone sodium 0·5 g and succinylcholine 50 mg followed by inflation of the lungs with oxygen. Spontaneous respiration did not return until an hour later (normal period of apnœa 2–5 minutes), and the tidal exchange was inadequate until a further 30 minutes had elapsed During this period of apnœa electrodiagnostic examination revealed considerable neuromuscular block, direct muscle stimulation was normal, and there was a double type of intensity duration curve This indicated that the persistence of muscle paralysis was of peripheral origin A sample of blood was taken for determination of cholinesterase and pseudocholinesterase levels

Bronchial Biopsy (Dr J L Pinniger)—Microscopy showed an oat cell carcinoma Culture gave a profuse growth of pneumococci and a few colonies of *Neisseria catarrhalis*

Electrodiagnosis—Several of the weak muscles were examined but showed no significant abnormalities of the intensity duration curves No fibrillation potentials were detected on electromyography Motor-unit action potentials and interference pattern were within normal limits in the affected muscles These findings were regarded as being against a diagnosis of a lesion producing lower motor neurone degeneration.

Cholinesterase Levels (Dr H Lehmann)—Pseudocholinesterase 56 units (normal limits 51–121 units), true cholinesterase 135 units (normal limits 75–150 units)

Liver function Tests—Total protein 6 1% (albumin 3 8%, globulin + fibrinogen 2 3%), thymol turbidity 2 units, alkaline phosphatase 8 5 units

Blood count showed Hb 78%, red cells 3,830,000 per c mm., packed cell volume 33%, mean corpuscular volume 82 c mm., mean corpuscular Hb concentration 33%, white cells 9900 per c.mm (differential count normal), erythrocyte sedimentation rate 122 mm in 1 hour (Westergren)

NEUROMUSCULAR TRANSMISSION

The prolonged apnœa following the administration of succinylcholine and occurring in association with the symptoms of myasthenia and in the presence of normal cholinesterase activity suggested a change in response of the motor end plate to depolarising drugs

Response to Decamethonium—The administration of intravenous decamethonium 2 mg (0 033 mg per kg) to the conscious patient in two separate doses of 1 mg was followed by paralysis of skeletal muscle Respiration became severely embarrassed and had to be assisted Despite the striking loss of volitional activity the action potentials of the hypothenar muscles of the right hand, obtained by supramaximal stimulation of the ulnar nerve at the wrist ten times a second, were maintained Further, a minute after the intravenous injection of 20 mg of ‘Tensilon’ (a short acting neostigmine analogue) respiration returned to normal and the patient opened his eyes and talked freely The recovery of grip strength was less dramatic

This response to decamethonium and its reversal by tensilon are similar to those described for myasthenia gravis (Churchill Davidson and Richardson 1953)

Response to d Tubocurarine—The well known sensitivity of myasthenia muscle was exhibited by this case After the induction of anæsthesia with thiopentone 0 5 mg followed by nitrous oxide and oxygen the intravenous injection of *d*-tubocurarine 3 75 mg (0 0625 mg per kg) led to apnœa lasting 10 minutes, with a further period of 12 minutes during which respirations were of inadequate volume Such a dose of curare would not stop respiratory activity in a normal man of similar physique

Response to Succinylcholine—With the patient similarly anæsthetised, intravenous succinylcholine 7 5 mg (0 125 mg per kg) caused 6 minutes apnœa with a further 4 minutes' inadequate tidal exchange On repetition of this procedure the injection of tensilon 20 mg led to an immediate improvement in respiratory volume

Response to Neostigmine—The patient was given neostigmine sulphate 15 mg by mouth three times a day for two weeks and this improved his hoarseness and skeletal muscle power

Discussion

The association of carcinoma of the bronchus with the symptoms of myasthenia has not previously been reported. In the present case there is strong clinical evidence for believing that the severe muscle weakness is of the myasthenic type, and this belief is supported by the following facts

(1) There is no evidence of any lower motor neurone degenerati

(2) There is increased sensitivity of the skeletal musculature for *d*-tubocurarine

(3) Electromyographic measurements following the intravenous injection of decamethonium were similar to those seen in cases of myasthenia gravis (Churchill Davidson and Richardson 1952)

(4) The neuromuscular block produced by decamethonium and succinylcholine was reversed by tensilon, a neostigmine analogue

(5) Considerable symptomatic improvement followed oral neostigmine therapy

For a clearer understanding of the abnormality of neuromuscular transmission in the present case it is necessary to recapitulate certain features In normal people both decamethonium and succinylcholine act at the neuromuscular junction essentially like acetylcholine they produce an area of depolarisation on the muscle membrane in the region of the motor end plate—i e, depolarisation block This type of block is potentiated by anti cholinesterase substances In contrast, *d*-tubocurarine raises the excitation threshold of the motor end-plate for acetylcholine, leading to a neuromuscular block by competitive inhibition Such a block is rapidly reversed by anti cholinesterase substances

There is, however, a third type of neuromuscular block—described in animals as a “dual mode of response to depolarising agents”—in which the motor end plate first responds by depolarisation followed by a transition to a block of the competitive inhibition type (Zaimis 1952) In myasthenia gravis it has been suggested that the abnormality of neuromuscular transmission is one of altered response of the motor end-plates from depolarisation to the dual mode of action, with the result that the end-plate responds to acetylcholine, decamethonium, and succinylcholine first by depolarisation and then by competitive inhibition (Churchill Davidson and Richardson 1953) Only on such a basis can the response to decamethonium, succinylcholine, and *d*-tubocurarine in the present case be satisfactorily explained, for in each instance a neuromuscular block of the competitive inhibition type resulted, and this was readily reversed by anti cholinesterase drugs

The period of prolonged apnœa that followed the injection of succinylcholine is of great interest Clearly this cannot be explained by a low plasma cholinesterase level, which is the common cause of this condition (Bourne 1953) If it had been possible to distinguish between a low plasma-cholinesterase level and myasthenia during the period of apnœa, a dose of neostigmine would almost certainly have reversed the paralysis Further, it is interesting to note that three cases of prolonged apnœa after the administration of succinylcholine which dramatically improved on the injection of neostigmine have already been reported (Hamer Hodges 1953, Grant 1952, Ruddell 1952)

There remains, therefore, to be considered the possible relation between carcinoma of the lung and myasthenia. Any views must be entirely speculative, but in the previous case seen at this hospital the removal of the tumour led to a dramatic symptomatic improvement Similarly, cases of myasthenia gravis have been reported in which removal of the thymus and the thyroid glands have been followed by an amelioration of the symptoms. The rôle of the thymus gland in myasthenia remains unknown, but it would be of great interest to know whether this specific change in the reaction of the motor end-plate—myasthenia—occurs in association with other forms of carcinoma

Summary

A case of carcinoma of the lung showing myasthenic weakness is described

Investigations showed that the response of the motor end plate to *d* tubocurarine, decamethonium, and succinylcholine was similar to that seen in myasthenia gravis

The significance of the prolonged apnœa following ccinylcholine is discussed

We wish to thank Dr. H. Lehmann of St Bartholomew's ospital, for the plasma-cholinesterase determinations We knowledge with gratitude that the expenses of this investi tion were borne by a grant from the endowment fund of ; Thomas's Hospital Miss J F Davenport rendered valuable ecretarial assistance

POLYMYXIN B

AN INTRATHECAL REACTION

R J McGILL
M.B N.Z., M.R.C.P.E.
HYSICIAN ROYAL SOUTH HANTS HOSPITAL, SOUTHAMPTON
ND LYMINGTON HOSPITAL, HANTS *CHIEF CLINICAL ASSISTANT*
BROMPTON HOSPITAL, LONDON

DENNIS MENDEL
M.B Lond. M.R C P
ESIDENT MEDICAL OFFICER, LYMINGTON HOSPITAL, HANTS

POLYMYXIN B is becoming increasingly recognised as potent bactericidal weapon against certain gram egative organisms. To be effective in meningeal nfections it must be given intrathecally it does not ass the blood brain barrier (Brownlee and Bushby 1948)

Polymyxin B is irritant to tissue especially when njected intramuscularly a pleomorphic reaction in the erebrospinal fluid (C.S.F) has been reported together ith an increase in the meningeal symptoms (Swift and Bushby 1951), but no emphasis has been placed on the ossibility of more severe sequelæ. On the contrary s injection intrathecally has been very recently said to e harmless (Jawetz 1952, *British Medical Journal* 1953)

CASE RECORD

A married woman aged 28 was admitted on Nov 10 1952 ith three days history of malaise, severe occipital headache ausea and vomiting and occasional rigors with aching pains n the limbs. Mild photophobia was noticed. No specific eakness was present and there were no other symptoms. She had had a recent frontal sinus infection for which a ubmucous resection had been advised.

On admission her temperature was 99·4 F pulse-rate 80 espirations 20 a minute, and blood pressure 120/60 mm. Hg She was perfectly conscious, but in considerable distress, with evere neck rigidity and tender occipital and upper dorsal thoracic muscles. Kernig's test was positive at 45 with pain. The right grip was rather weak. No other motor weakness was found. The right knee-jerk was accentuated. Otherwise routine clinical examination revealed no abnormality

Lumbar puncture produced clear C.S.F under a pressure of 125 mm. H_2O which was transmitted normally The C.S.F contained 155 small mononuclear cells per c.mm and protein 40 mg per 100 ml The Wassermann reaction and Lange test were negative.

Progress—On Nov 17 there was increasing weakness in the right arm. The right knee jerk remained accentuated. There were no sensory changes. Catheterisation became necessary because of retention of urine A few colonies of *Bacterium fæcalis-alkaligenes* were at this stage grown in the first specimen of C.S.F On Nov 18 the neck rigidity was slightly increased the right knee jerk was much diminished, and a white cell-count showed 7200 (polymorphs 48-0 lymphocytes 1948 monocytes 144 eosinophils 216) per c.mm. The C.S.F was clear and under normal pressure and contained 165 small mononuclear cells per c.mm., protein 40 mg per 100 ml., and chloride 760 mg per 100 ml. Culture produced a pure growth of an organism identical with that previously isolated On Nov 21 severe headache and vomiting recurred Neck rigidity was still present and there was no change in neurological signs. It was now reasonably certain that the responsible organism was *Bact fæcalis-alkaligenes* Radiography of the spine and skull a high nasal swab and culture of the stools did not help to elucidate the source of the infection. The organism was found to be sensitive only to polymyxin B The patient was deteriorating rapidly with severe headache meningism, and vomiting the ankle-jerks were still present. The fact that the organism had been isolated twice decided us to use polymyxin B

Treatment and Course.—On Nov 22 treatment was begun with polymyxin B (the later or purified type) 100 000 units intrathecally b.d and 250 000 units intramuscularly six hourly Twelve hours after the first intrathecal injection the C.S.F became turbid and the patient more febrile, meningism was much increased. The sites of the intramuscular injections were painful Three intrathecal injections were given twelve hourly but owing to the intense meningeal reaction further administration was stopped. On Nov 24 the C.S.F was cloudy and contained 4000 cells mainly polymorphs per c.mm., and chloride 680 mg per 100 ml. culture was sterile after forty-eight hours. On Nov 25 neck rigidity was severe and there was severe urinary retention The C.S.F was clearer and contained 990 cells (polymorphs 60% small mononuclears 30% large mononuclears 10%) per c.mm Culture was sterile after forty-eight hours. On Dec. 1 the neck rigidity had disappeared but the right ankle jerk was absent and the right knee jerk diminished. Sensation was normal, but there were generalised weakness of the legs and fæcal incontinence in addition to the urinary retention By Dec. 13 a complete cauda-equina lesion had developed with motor weakness, loss of ankle-jerks, a saddle shaped area of anæsthesia, urinary retention and fæcal incontinence The right knee jerk remained diminished and there was much muscular weakness in both legs. The C.S.F on Dec. 8 was clear but contained 191 small mononuclear cells per c.mm, protein 170 mg per 100 ml and chloride 700 mg per 100 ml On Dec. 15 the C.S.F was clear and under a pressure of 70 mm. H_2O transmitted normally It contained 71 small mononuclear cells per c.mm., protein 270 mg per 100 ml chloride 710 mg per 100 ml., and sugar 70 mg per 100 ml In view of the increased amount of protein in the C.S.F and the neurological signs it was considered that a partial arachnoid block was developing Accordingly streptokinase 100 units was given intrathecally in 1 ml of physiological saline solution. The patient was transferred to the West End Hospital for Nervous Diseases under the care of Dr C. Worster Drought. After that her clinical condition gradually improved, and the amount of protein in the C.S.F slowly decreased to such an extent that further intrathecal therapy was not indicated The C.S.F towards the end of January was almost normal containing 2 lymphocytes per c.mm. and protein 45 mg per 100 ml and a white-cell count was normal Two cultures of the C.S.F., one in this hospital and one in the West End Hospital for Nervous Diseases, revealed no acid fast bacilli (culture on Löwenstein medium and animal inoculation)

Follow-up—The patient's present state shows much improvement in power of both the right arm and the legs; she is walking well the right knee-jerk is still diminished, the left has improved both ankle-jerks are still absent, and sensory impairment is still present but of considerably less severity Sphincteric control is satisfactory

DISCUSSION

There is no doubt of the antibacterial effectiveness of polymyxin B A generalised meningeal reaction was produced, and, as it subsided an arachnoiditis affecting the cauda equina became apparent The rapid loss of ankle-jerks soon after intrathecal medication supports the view that this was due to the polymyxin and not to the meningitis.

A transient neurotoxæmia has been reported (Jawetz 1952), but no objective neurological signs were produced The evidence in the present case suggests that the damage is due to more than this.

Since polymyxin B is recognised as an irritant [illegible] injected intramuscularly, caution should [illegible] in using it intrathecally We emphasise that [illegible] is of undoubted value and should be used [illegible] Polymyxin B has been given [illegible] units intrathecally without ill effect There is no history in this patient of drug sensitivity or allergy

We suggest that, when used intrathecally, polymyxin B be given in much greater dilution initially, the concentration being increased rapidly in subsequent injections

SUMMARY

A case of meningitis due to *Bact fæcalis alkaligenes* successfully treated with polymyxin B is recorded

A cauda equina lesion complicated the therapy

A low dosage is advised initially

ROYAL SOCIETY OF MEDICINE

Hypothermia and Hibernation

THE section of anæsthetics met on Dec 4, under the chairmanship of Prof R R MACINTOSH, its president, to hear three short papers

ANTI HISTAMINES IN ANÆSTHESIA

Dr A J W BEARD noted that anti-histamine drugs are members of a group which are said to inhibit acetylcholine, adrenaline, and histamine in varying degrees He described three effects of interest to anæsthetists sedative, anti-emetic, and that producing hypothermia The sedative effects differ from those of barbiturates and the experimental evidence for this was described, as were the effects on man He illustrated the sleep prolonging effect of chlorpromazine ('Largactil'), the latest of these drugs, by a film If, Dr Beard said, mammals are curarised or deeply anæsthetised to prevent shivering, the body may be cooled in various ways with consequent reduction in oxygen need so also after anti histamines or more especially chlorpromazine So called "artificial hibernation," an unfortunate term, is produced in France by the "lytic cocktail"—a mixture of chlorpromazine, pethidine, and promethazine ('Phenergan') The blood-pressure falls a little, especially with posture or other agents, thus diminishing bleeding, in his experience the pulse-rate has often risen, especially in the early stages, to levels above 100 per minute Postoperatively, patients often lie quiet and contented and free from pain He has found that administration of the mixture, or of chlorpromazine alone, greatly decreases the quantity of anæsthetic agents—particularly thiopentone—needed later He emphasised how peaceable are the laryngeal and bronchial reflexes, and briefly described applications in thoracic surgery, as well as mentioning uses in vomiting, in severe pain, and in pædiatrics, obstetrics, and cerebral surgery

It is possible that the benefit to anæsthesia from these drugs, and from some newer combinations in use on the Continent, may be due to their sedative and their anti shock properties, which are probably related to their sympathetic-blocking effects This suggestion derives from experimental work, particularly that of Freeman and of Wiggers Dr Beard said that he had tried to provide a background to the subject which would be filled in by the teams who will eventually be publishing their results He thought that while uncritical enthusiasm was unreasonable, so was condemnation without reading the literature or trying the drugs His own feeling was that in some cases, he would now be sorry to be without their help

EXPERIMENTS WITH DEEP HYPOTHERMIA

Dr A A JUVENELLE (Paris) sought to define hypotherm[illegible] cooling of the whole body, as distinct from refri[illegible] which implies part of the body By definition, hypothermia should be reserved for a temperature fall to 25°C, while deep hypothermia should describe temperatures below this In dogs he has maintained life by an artificial circulation, in the presence of ventricular fibrillation, at a very low temperature for up to seven hours After re-warming normal rhythm returns, and recovery is complete in 40% of animals Biochemical changes during hypothermia are similar to those found in hibernating animals and are reversible by rewarming Cold does not prevent tissues from getting oxygen from the blood Dr Juvenelle thought that clinically the risks of hypothermia should be balanced against the surgical risks He commented on the poor elimination of barbiturates from the body in the cold state

APPLICATION OF THE HEART-LUNG MACHINE TO MAN

Dr D G MELROSE recalled that, while hypothermia is a means of reducing the oxygen needs of the body, the artificial circulation is expressly designed to add oxygen He briefly described the principles of the machine he has designed and showed how a similar machine has been used to aid a patient with very severe pulmonary fibrosis The apparatus is not yet sufficiently developed to take over the whole circulation but can be used safely for a part Deep hypothermia to levels below 26°C is unsafe, yet to obtain a reasonable time—say an hour—in which to operate within the heart by this method, a temperature of about 10°–7°C would be needed In Dr Melrose's opinion, it is best to reduce the temperature of the body to a safe level, and one at which the heart lung machine can adequately take over the circulation when the heart is stopped This, he thought, is how hypothermia and the heart lung machine are likely to be combined in the future He has been impressed with the difficulty of reversing ventricular fibrillation in the cold state, and prefers to avoid this complication

DISCUSSION

Dr C F SCURR described three cases in which hypothermia had been used successfully for cardiac operations in children He noted that the temperature fall might overshoot the desired level despite the start of re warming In these cases, though bradycardia was pronounced, no signs of increase in cardiac irritability were noticed despite direct handling of the heart

Dr CECIL GRAY has had experience of hypothermia in 30 cases He remarked on the value of the lytic cocktail for preventing shivering, and regarded chlorpromazine as the active ingredient from this point of view In adults this is in every respect a preferable method of preventing shivering to either anæsthesia or curarisation. He drew attention to the overshoot in temperature fall which is likely to occur following the opening of the thoracic cavity It appears that at temperatures below 26°C manipulation of the heart may precipitate fibrillation, a further danger at the low temperature is that there is interference with blood clotting—a particularly dangerous effect where there is liver damage with lowered prothrombin Dr Gray suggested that at our present state of knowledge the advantages do not outweigh the dangers of temperatures below 28°C

Dr J W DUNDEE said that the decrease in oxygen consumption produced in animals by chlorpromazine seemed to be greater than that produced by morphine He had used the drug in combination with mild hypothermia for some cases of thyrotoxicosis, and in these cases he had brought the pulse-rate to normal levels before operation, when more usual medical methods had failed.

Most other speakers were impressed with the value of both the anti histamines and artificial hibernation in anæsthesia and in other branches of medicine, but some asked whether a large number of the cases suggested as suitable could not be anæsthetised with equal success by more orthodox techniques

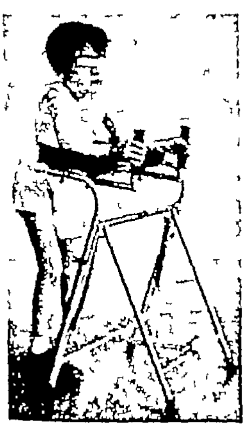
New Inventions

SPRING-ASSISTED WALKING AID

NUMEROUS devices have been constructed for the use of patients who have difficulty in keeping their balance or are apprehensive about the use of crutches during rehabilitation following lower-limb fractures. The apparatus described here gives patients a feeling of confidence because it is exceedingly stable and, being spring assisted, calls for very little effort during movement.

It is made from tubular steel in the form of two pairs of legs, front and rear, held rigidly apart by welded steel tubes parallel to the ground and articulating at the apex by a similar length of tube. Two lengths of steel tube are welded to the outer sides of the rear legs. Into these fits a framework carrying upholstered arm rests and rubber-covered hand-grips. Simple clamping devices are provided to allow for variations in both height and width of the combined hand-grips and arm rests.

A sliding frame mounted on the lower cross members of the front and rear legs incorporates an adjustment for the length of stride and a swivel device to permit folding of the apparatus for storage or transport. A pair of springs between the front and rear legs give sufficient tension to open the apparatus to the fullest extent of its "stride."



With the patient standing upright close to the rear legs of the apparatus, the framework for the arm rests is adjusted so that the patient's forearms, when flexed to a right angle, rest comfortably on the arm rests.

The length of stride may be altered by the adjustable stop on the sliding framework between the front and rear legs.

With the legs of the apparatus in their fully extended position the patient is instructed to lean slightly forward pushing against the hand-grips. This causes the rear legs to leave the ground as the patient's weight falls on the front legs. The patient next leans on the forearm rests, causing the rear legs to swing forward into the closed position when, on continued forearm pressure they will come to rest on the ground. At this point the patient should take a step forward. When the patient removes the weight from the forearm rest and gives the hand grips a slight upward tilt, the front legs leave the ground, and their controlling springs cause them to extend fully. The cycle of movement is then repeated.

The apparatus has been made in two sizes to suit adults or children, and incorporates simple adjustment for height, width, and length of stride. Since the legs fold together, it is convenient for transport or storage.

It has been found useful in the rehabilitation of a wide variety of locomotor disabilities—e.g. cerebral palsy poliomyelitis, disseminated sclerosis, and other neurological conditions with a disturbed sense of balance. In the rehabilitation of the aged and in orthopædic cases it gives patients a much greater feeling of confidence than do the traditional types of walking-aids. Since the apparatus is spring assisted very little effort is required in its use. This feature is particularly striking in poliomyelitis patients with a greatly weakened hand grip who find the manipulation of crutches so difficult.

The Swindon Hospital Management Committee have made funds available for the development of this apparatus. It has been made by the firm of Spenser Harris, Engineers, Cirencester to whom I am indebted for much help in its development and construction.

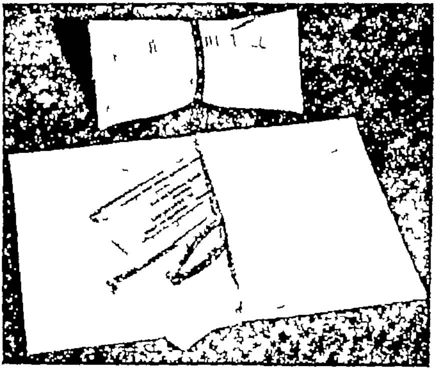
PLASTIC SPECIMEN-POUCH

THE transfer of large specimens from the operating theatre or the post-mortem room to the histology department poses a recurring problem to theatre sisters and pathologists, particularly in areas where the laboratory serves outlying hospitals. Many specimens—e.g., mastectomy specimens—are too bulky for the largest size of screw-capped jar, and it is customary to send such specimens in dressing bowls, hand bowls, kidney dishes, all-glass jars, &c., which are heavy and cumbersome, often leak in transit and must be returned later to their owners. Sometimes large specimens are forced into glass containers of inadequate capacity and their removal after fixation may necessitate cutting the specimen in the jar or even breaking the jar. Moreover the lack of suitable containers encourages the undesirable practice of sending to the laboratory small representative pieces instead of the whole specimen.

The pouch described here was designed to overcome this difficulty. It has proved a satisfactory alternative to metal and glass containers and is preferred by those who send and those who receive specimens. The design and method given below may be modified to suit individual tastes and requirements.

The pouches are made of white opaque Denlon plastic, and are issued to theatres in batches of two sizes.



The smaller pouch with the flap extended measures 16 × 10 in. and the larger 18 × 12 in. Each pouch contains a piece of folded lint 15 or 18 in. square a broad rubber band and a request form. The histology department of the hospital is printed free-hand with a ball point pen on the outer side of the flap; the printing withstands washing and rubbing, and is intended not only to indicate the destination of the specimen but also to prevent misappropriation of the pouches.

Theatre sisters are given the following instructions:

(1) Soak the lint square in 5% formol-saline and squeeze out excess of fluid. Wrap the specimen in the moistened lint (fluff side next to specimen) and place it in the pouch.

(2) Complete the request form and place it between the pouch and the flap. Close (with a fold if necessary) and secure with the rubber band.

(3) Do not delay sending the specimen to the laboratory the formol-saline acts as a preservative rather than a fixative.

When the specimen reaches the laboratory it is removed from the plastic pouch and transferred to a vessel containing fixative until ready for examination. If a tank is used *for fixation and storage the lint can be noosed with* string to form a bag for the specimen.

After use the pouch is washed, dried, and prepared for reissue. The plastic is inexpensive, tough and durable and can be used repeatedly.

These pouches can be obtained from Charles Thackray Ltd. Leeds.

Reviews of Books

Our National Ill Health Service

Surgeon Vice-Admiral Sir SHELDON F DUDLEY, K C B, M D, LL.D, F.R C P, F R S, medical director general, Royal Navy, June, 1941-January, 1946 London Watts 1953 Pp 225 15s

THIS is a stimulating and provocative book in which every reader, no matter what his views, will find something to applaud and something to deprecate, probably with equal enthusiasm Sir Sheldon Dudley's main thesis is that the National Health Service is misnamed, since 90 % of its effort and finance is put into curing or caring for the sick and only 10 % into preventing disease, that this disproportion needs correcting, and that the Services have a great deal to teach the civilians on this matter In the process, like a lively dog that cannot pass a side-path, he rushes down some fascinating byways, ranging from placebos to chimneysweep children, and from " the atebrin story " to speculations on the effect of successful psychiatric treatment on Dr Johnson, Darwin, and Florence Nightingale His main sections are entitled the preservation of national health, debunking, the preservation of global health, the Army's struggle for hygiene discipline (an example for all health administrators), and the preservation of health in the Royal Navy (a guide to all defenders of national health) His arrows hit so many targets—some, indeed, shooting down his own arguments—that we stand delighted and forget to take cover until a shaft whistles in our own direction There are occasional slips *our* Sir John Simon was never made a peer, however much he may have deserved it, and Prof James Mackintosh was one time C.M.O of the Department of Health for Scotland, not of the Ministry of Health In his unfavourable comparisons of the civilian health services with those of the Army and Navy, Sir Sheldon acknowledges the advantages of discipline and the ability to give orders but perhaps fails to give due weight to the selected character of the Service " herds " The particular preventive programmes on which he would concentrate if his opinions prevailed, and finance were no object, are not entirely satisfying—being limited to health centres (including the Peckham experiment), research into the social sciences, and the abolition of pneumoconiosis. But his book deserves to be widely read, as the product of real professional eminence a warm heart, an informed mind, and a point of view which has been too much neglected in our National Health Service

Parkinson's Disease and its Surgical Treatment

LESLIE C OLIVER, F R C S, neurosurgeon, West End Hospital for Nervous Diseases London H K. Lewis 1953 Pp 88 12s 6d

IN this monograph Mr Oliver presents his results of spinal cord surgery for the relief of parkinsonism At first he used the original Putnam procedure of lateral pyramidotomy, and he concludes that this operation is rarely indicated for bilateral tremor, but that it brings improvement in about half of unilateral cases More recently he has extended this operation to complete the section of the lateral column

In 14 such cases the tremor was substantially relieved for at least a year to the time of follow up, but at the cost of a permanent contralateral analgesia and of homolateral hemiparesis sometimes quite mild The postoperative Horner's syndrome usually cleared up Nevertheless, these results show that the unilateral tremor must be long standing and the disability severe to justify the procedure, and Mr Oliver believes that its use in a steadily progressive case can only make matters worse

This work affords further evidence that the pyramidal tract in the cord is not the discrete bundle of the anatomical textbooks The variability in the hemiplegia following its section, and the fact that, broadly speaking, the more extensive the lateral section the better the chance of relieving tremor and the greater the risk of hemiplegia, suggest that, though the fibres of the lateral pyramid [illegible] t are concentrated in the posterior half of the lateral column, they are distributed throughout this column Thus the difficulty of forecasting the effect of operation in an individual case is understandable.

The possibilities of cerebral surgery in this condition are also considered briefly The place of surgery here is still undecided, and Mr Oliver concludes justifiably that "there is at present no cure for Parkinson's disease, but in a small proportion of cases substantial improvement may be accomplished by surgery if great care is taken in the selection of patients "

Rudolf Virchow

ERWIN H. ACKERKNECHT, chairman, department of history of medicine, University of Wisconsin. Madison University of Wisconsin Press. 1953 Pp 242 $5 00

WE are apt to think of Virchow as a pathologist only, albeit the greatest of modern times Dr Ackerknecht shows us, however, that he was a gifted and many sided man who would certainly be remembered for reasons other than his contributions to pathology

From his youth onwards he was a social reformer, and he was conspicuous on the barricades in the revolution of 1848, the goal of which was to him the liberation of the working man In the city council of Berlin, to which he was elected in 1859, and in the Prussian parliament, where he remained from 1861 until his death in 1902, at the age of 81, he championed the cause of social reform and on one occasion he was challenged by his opponent Bismarck to a duel As an anthropologist he shattered the myth of Teutonic superiority and made important investigations on Trojan, Egyptian, and Etruscan cultures. In medicine his influence was felt far outside the circles of academic pathology When he went to Berlin in 1856 he asked for, and for many years directed, a clinical division of the hospital, and with the aid of Frederick III he established the first children's hospital in the Prussian capital Public health, sanitation, school reform, and reform of the medical profession all interested him. In addition he was a medical historian.

Dr Ackerknecht, in his scholarly book, attempts to review the work of Virchow and assess his influence during the second half of the 19th century in the fields of medicine, anthropology, and German liberalism, and gives a masterly account of the development of the science of pathology of that time, and especially the history of the cellular theory As a biographer he is accurate and strictly fair in his appraisal of a figure who was in danger, until this volume appeared, of becoming legendary His admiration for him is clearly profound " His greatness," he writes, " transcends the fields he worked in or the nation he belonged to " Dr Ackerknecht is well qualified to write on Virchow because not only is he a doctor, anthropologist, and medical historian, but being a native of Virchow's home province he knew many of his acquaintances.

Handbook of Practical Bacteriology (9th ed E & S Livingstone 1953 Pp 677 25s) —' Mackie and McCartney " has no rivals, and there must be very few bacteriological laboratories that are without a well thumbed and battered copy—which can now go into honourable retirement The latest edition shows no major changes but many new methods have been introduced, and material that was formerly collected in appendices now finds a place in the text These changes have produced only a small increase in the size of the book The technical section is particularly valuable for its excellent articles on microscopy and media-making and there is a new section dealing with the filter paper disc method of testing sensitivity to antibiotics. Inevitably, some bacteriologists may miss one or other of their favourite methods or media for instance, in describing Jungmann's method for the liquefaction of tuberculous sputum, 1 vol hydrogen peroxide is recommended though 10 vol is almost certainly better The section on virus diseases might usefully include information on the types of specimen that are required by the laboratory for diagnostic purposes, and a table of instructions about the time and method of collection and dispatch would be helpful and could perhaps replace the present lists of human and animal diseases due to viruses There is no doubt that the book will maintain its reputation as a thoroughly reliable, practical, and amazingly comprehensive guide to bacteriological technique

THE LANCET

LONDON SATURDAY, DEC 19, 1953

Infection at Work

In any occupation which involves close contact with the public and the public's germs, there must be an increased risk of infection. Less obvious, however are risks which may follow changes in the organisation of man power in industry Since the beginning of the Industrial Revolution in this country around 1820, the movements and aggregation of people at work in factories have had serious epidemiological consequences Susceptible people from the country became crowded together both in their new homes and at their place of work in the towns, and, despite the raising of the standard of living by increased productivity the toll of infectious disease in general, and of tuberculosis in particular, increased ominously Even now, the evolution of our industrial society is not complete, and against the production engineer's cry for bigger and apparently better workshops, Dr ALICE STEWART and her colleagues at Oxford have sounded a persistent note of caution. They have been mainly concerned with the prevalence of tuberculosis in the boot and shoe factories centred around Northampton The alarming rise in the tuberculosis death rate in that industry dates from the move, towards the end of the last century, from cottage workshop to modern factory—a move which increased the size of the working group CAIRNS and STEWART[1] believe that in the rise and fall of tuberculosis mortality over the last century in, for example the printing trade we are seeing a slow motion epidemic starting with the exposure of large numbers of susceptible people to infective carriers in crowded factories, and dying away as all epidemics must when there are no more susceptibles in these industrial communities The unusually high mortality rate from tuberculosis in trades such as printing can be partly explained by the attraction which this work has for men of less robust physique who may choose such an occupation early in life or turn to it later because they cannot cope with heavier jobs. But a study of the results of medical board examinations of recruits coming from the boot and shoe trades does not suggest that this is an important part of the explanation In industrial communities such as those in Northampton there is much contact in the home as well as in the workshop and there is some evidence of the house-to-house spread of tuberculosis in this city,[2] as in others[3] More important, however seem to be wide differences in the incidence of tuberculosis among men working in different factory environments An analysis[4] of surveys by mass miniature radiography in the boot and shoe industry and of notifications of pulmonary tuberculosis showed that among factory workers the incidence of tuberculosis was more closely related to the size of the working group than to the ventilation or other physical characteristics of the factory HEWITT and STEWART[5] showed that although there is an apparent connection between the incidence of tuberculosis in a factory unit and the area of work space per worker in it the association is more apparent than real, since the less crowded workshops tend to house those with heavier jobs—with appropriate names like "rough stuff"—so that the less robust workers may seldom find employment there Indeed, within occupational groups, the tuberculosis notification rates are found to be highest, not in the smaller "overcrowded" work spaces, but in large production units—often well lit and well ventilated—where many workers are in continual daily contact Where these larger spaces are divided by partitions there is evidence that tuberculosis morbidity is less.

In attempting to express these relationships in quantitative terms, HEWITT and STEWART first show that there is no simple constant ratio between increases in the number of workers in the occupational unit and the incidence of tuberculosis among them—in other words, the graph relating the one to the other is not a straight line The curve could be better expressed mathematically by introducing higher powers of the number of people in the unit, but such a curve, unlike the graph of the actual observations, would not tend towards a fixed maximum. HEWITT and STEWART therefore prefer to restate an epidemic theory used by FROST[6] this expresses the incidence of a disease within a closed community, such as a workshop, as the product of the number or proportion of susceptibles and the risk of their making effective contact with an infected member of the group On this basis the risk of becoming infected by effective contact with a carrier can be worked out for groups of various sizes In this instance, neither the proportion of susceptibles nor the carrier rate was known, but they were estimated from the data, and these estimates were used to give theoretical expressions which describe very precisely the way in which the risk of infection varies between working groups of different sizes What is more estimates can be made of the proportion of cases of tuberculosis among adult workers which may be attributable to contacts not made at work. This proportion depends on the size of the working group and ranges from 40 to 60% and it may also be affected by the total population of the factory enclosing these individual work spaces or groups.

The same theory has been applied in a further study of the spread of infection among office staffs. During the 1951 influenza epidemic, ACHESON and HEWITT[7] traced the spread of influenza among the employees of the University Press at Oxford They found it impossible to relate the incidence of the disease either to the closeness of people to one another or to the crowding of the office, as measured by the average area per worker But there was some indication that the attack rate was lower in the rooms with fewer people in them With a disease like influenza where the carrier rate is perhaps as high as 5% and where each infected person becomes an added source of infection, the same theory is not entirely appropriate But it can be used to point out the likelihood that, since the probability of escaping infection depends upon the level of the carrier-rate, a high initial carrier rate, as in influenza, means a rapid saturation of a highly susceptible group with infection. In these circumstances, any increase in the size of the working group beyond a certain point, say 20 workers, makes little difference to the group's attack-rate during the epidemic It is thus hardly surprising that among the workers in the large rooms of the Post Office building surveyed in the epidemiological inquiry described in this issue by Dr **Reid** and his colleagues, there is no striking difference between the attack-rates for the common cold in different rooms

It would be easy for an armchair critic to suggest reasons why the dangers of cross-infection at work are more apparent than real Differences in office size, for example, may be associated with considerable differences in sex and age composition, in jobs, and in social position—all of which are certainly relevant to the incidence of infectious disease By reason of their size, large offices tend to have poorer industrial morale and lower standards of reporting the true causes of absence In chronic infectious illness, such as tuberculosis, large offices with a high rate of labour turnover make any estimate of the real numbers of effective human contacts over a period of work rather vague That 40% of tuberculous infections among adults are due to work contacts is at best, therefore, an informed guess , but that the risks are appreciable is seen in the doubling of the infection-rate among urban children after leaving school [8]

Some of the practical difficulties of these investigations can be overcome, as in the Post Office study, by systematic interviewing and by combining morbidity surveys with objective measurement of environmental conditions and bacterial contamination of the air The effect of climate may seem to have been all-important , but, of the colds where a history of known contact could be obtained, nearly half were presumably contracted at work A third of the sickness absences in industry are due to respiratory disease , so there is good cause to pursue these preliminary essays in epidemiological method

Radiotherapy and Bronchial Carcinoma

It is hard to find out how far radiotherapy prolongs the life of patients with bronchial carcinoma In general, those selected for treatment of the primary tumour are in a less advanced stage of the disease than those rejected , and to compare the subsequent history of the groups is not a valid measure of the effect of treatment Even if the groups are assumed to be comparable, the effect on survival-time is apparently not very great Thus, in the Survey of Cancer in London,[9] the mean duration of life of untreated patients was found to be nine months , among the treated patients, the expectation was sixteen months for those without evidence of metastases and thirteen months for the larger group with metastases Although there are many reports about the survival of patients after radiotherapy, few include details of the palliation achieved **Brown** [10] recorded the results in 189 patients treated at St Bartholomew's Hospital , in 53% the symptoms were improved, in 21% they were unchanged, and in 26% the condition after treatment was worse than before And the improvement was short-lived in many of those who benefited Only about a quarter of those treated were better for longer than three months, and only 20% survived longer than a year

Palliation is the mitigation of suffering , and suffering is very difficult, if not impossible, to measure Symptoms and suffering are not the same, for a patient may lose his pain but suffer much more from the frequent journeys to the hospital, the loss of work and money, and the knowledge that X-ray treatment usually means cancer On the other hand, his cough and dyspnœa may be worse, but he may suffer less because something dramatic is being done to help him The assessment of change under such circumstances is bound to be much influenced by the enthusiasm of the observer Certain types of suffering, however, can be more accurately described and recorded than others Compression of the superior vena cava, for instance, can cause such distress and such gross physical signs, that the effects of radiotherapy can be measured with little subjective error Yet it is difficult to find facts about it **Brown**,[10] for example, found that the condition was relieved in 18 out of 39 patients, but he does not state in how many the symptoms returned before the patient died and whether, when they did, they were as distressing as before treatment Changes in the distress caused by rapidly accumulating pleural effusions can be more precisely assessed , for the frequency of aspirations required to keep the patient comfortable before and after treatment can be compared There have been several reports of the use of intrapleural radioactive isotopes for this purpose [11-15] **Seaman** et al [15] have treated 40 patients, who had effusions due to primary or secondary intrathoracic neoplasms, with radioactive colloidal gold (Au^{198}) 11 patients died within a month and contact was lost with 3 others But in 20 of the remaining 26 the formation of fluid appeared to have been inhibited, and 9 survived longer than six months The procedure seems simple to carry out and causes the patient little discomfort, though some patients had nausea and vomiting and felt tired for a day or two after the injection Blood stained effusions may become clearer and malignant cells may disappear from the fluid [14] **Walton** [13] treated 18 patients in this way and he considered that 7 had benefited greatly and 4 slightly He noted that those in poor general condition appeared to deteriorate more rapidly after treatment, and it seems reasonable to treat such patients only if the symptoms due to the large effusion are very distressing indeed The diminished formation of fluid may not become apparent until a few weeks after treatment

Radioactive isotopes have also been used to attack the primary tumour in the lung **Muller** and

ROSSIER [16] injected radioactive gold into a branch of the pulmonary artery of animals by means of a cardiac catheter, and they have done the same thing in 4 patients The gold was carried on particles of charcoal of such a size that they were arrested in the fine blood vessels of the selected lobe BRYANT et al [17] used the intrabronchial route in dogs instilling the colloidal gold solution into a segmental bronchus or injecting it in the wall of the main bronchus There was considerable necrosis of the selected part of the lung but high radioactivity was demonstrated in the draining lymph nodes HAHN and CAROTHERS [18] found that silver-coated gold colloids spread more rapidly in the lymphatics of dogs and caused less lung damage Even so, much necrosis followed. There was considerable variation between different dogs in spread and concentration of the isotope in the lymphatic system The presence of a lung tumour and malignant tissue in the lymphatics might make the spread in man even more variable than in animals HAHN et al [19] used the silver coated gold in a patient with advanced bronchial carcinoma, a total of 78 millicuries being introduced into the bronchi of the affected lung on three occasions within ten days The patient tolerated the gold well and high radioactivity was demonstrated in the mediastinal region, but he died fifty days later There were no gross lesions in the lung that could be attributed to irradiation necrosis, although microscopically there was considerable inflammatory reaction. HAHN et al. suggest that the method may be useful preoperatively, the isotopes being introduced into the mediastinal lymphatics by way of the non affected lobe of the lung about two weeks before pneumonectomy, as the lung would later be removed some necrosis of healthy tissue would not matter But it is frequently impossible to be certain before operation that the lung can be removed Nevertheless the method offers some prospect of attacking metastases in the mediastinal nodes Radioactive cobalt has also been used to irradiate the hilar region after lung resection, the cobalt solution was introduced through a catheter into a bag which was kept in a position overlying the hilum and removed after a week.[20] The catheter was passed through a stab incision in the chest wall after pneumonectomy This procedure seems potentially unsafe, for it irradiates not only any tumour left behind but also the bronchial stump and the divided vessels, and high voltage irradiation of the hilar region, either before or after resection, is suspected to have caused bronchial fistulæ and empyemata

It is clearly necessary to explore every means of treating patients with bronchial carcinomas Since the great majority cannot be treated surgically, either because the disease is too widespread, or their general condition too poor, any new method of palliative treatment is worth investigating There may be in hospitals a tendency to divide patients into "treatable" and 'untreatable' groups and if the surgeon cannot remove the lung, to return the patient to the care of his general practitioner with the vague recommendation of symptomatic treatment MAYER and ROSWIT [21] have assembled an impressive list of what can be done to prolong useful life and ease the manner of dying, the methods they mention range from the 23-million volt betatron to high protein diets with emulsified fat supplements, from posterior rhizotomy to preprandial brandy and narcotics On the other hand, it is certainly possible to add to the patient's suffering in the attempt to ease it, and radiotherapy sometimes achieves less than drugs wisely used by a skilful general practitioner

Non-gonococcal Urethritis

ACCORDING to the report of the chief medical officer of the Ministry of Health, in 1952 new cases of non gonococcal urethritis in men attending public venereal disease clinics numbered 11 552, and new cases of gonorrhœa in men numbered 15,510 Non gonococcal urethritis has become an important problem for venereologists not only in this country but throughout the world, for gonorrhœa can now be quickly and easily treated by chemotherapy but non gonococcal urethritis is much less amenable to treatment.

Penicillin is ineffective against non gonococcal urethritis. Good results have been claimed for sulphadiazine [22] but not all venereologists agree on the efficacy of this drug given alone In any event the effect of treatment is not easily assessed, because the course and severity of the disease vary Furthermore, relapses are not uncommon, and observers may differ according to whether they ascribe recurrence of a discharge to relapse or to reinfection. HARKNESS [23] has now reported on 760 cases of the disease treated with the newer antibiotics, in an additional series of 156 patients the drug was chosen by random selection Success was greatest with oxytetracycline (terramycin) in doses of 0·5 g 6 hourly for 4 days, this gave 87% of cures Aureomycin was successful in 63% of cases, while streptomycin and chloramphenicol were less successful with 39% and 36% of successes. LYALL [24] has sought a method of treating both gonococcal and non gonococcal urethritis without masking the signs of syphilis acquired at the same time Such a method could be used in merchant ships which have no doctor LYALL found that one deep injection of 1 g of streptomycin, combined with 30 g of sulphathiazole in divided doses over 5 days, was effective in 93% of 182 cases of gonorrhœa and in 85% of 110 cases of non gonococcal urethritis These very encouraging results suggest that the newer antibiotics—particularly aureomycin and oxytetracycline—should be given routinely in the treatment of non gonococcal urethritis. Further experience will show whether they diminish the risk of complications and relapse.

HARKNESS drew attention to a close correlation between the bacteriostatic action of the antibiotics on pleuropneumonia like organisms isolated from urethral discharge and their clinical effect in non gonococcal urethritis The pleuropneumonia group of organisms are not well known to many medical bacteriologists although several species of the group—including the type species, the organism of contagious bovine pleuropneumonia—are of great importance as pathogens in veterinary practice **Edward** [25] examined the possibility that organisms of this group caused non-gonococcal urethritis, but was unable to decide from the existing evidence whether they were pathogenic in the genital tract of man and animals Since then he and **Nicol** [26] have isolated such organisms from the urethra of 26% of 140 men with non gonococcal urethritis This proportion of positive isolations is similar to that reported by other workers, so apparently three-quarters of cases of non-gonococcal urethritis may be unassociated with pleuropneumonia-like organisms There was no difference in the course of the disease, the response to treatment, or the liability to complications between patients with positive cultures and those with negative cultures In a control group of 90 men with no evidence of genital infection, positive urethral cultures were obtained from 11%, including 3 isolations from men who denied sexual intercourse **Nicol** and **Edward** also showed that there was no serological or other difference between strains isolated from cases of urethritis and strains isolated from healthy men. These workers regard the pleuropneumonia-like organisms as commensals of the human genital and lower alimentary tracts which play no significant part in non-gonococcal urethritis It is, however, possible that these genital strains, and other strains which inhabit the mouth, may occasionally produce localised suppurative lesions or blood-stream infection, and pleuropneumonia like organisms have been isolated from a few cases of brain abscess [27 28] and Henoch's purpura [28] Therefore, although there would seem to be little advantage to be gained from seeking these organisms routinely in cultures from genital infections, the possibility of their presence in suppurative and septicæmic conditions of unknown origin should be borne in mind

Non-gonococcal urethritis has been ascribed also to a virus, but for this there is still very little direct evidence Intracellular inclusions, some of them suggesting the presence of a virus, have been described, but other observers have failed to confirm the presence of these inclusions in a significant proportion of cases The cause of the disease is thus still a mystery, and there is a strong case "for an organized investigation into this condition, with adequate financial support, in which bacteriologists and clinicians should combine their resources" [29]

Metastatic complications, including arthritis, are not uncommon in non-gonococcal urethritis **Ford** [30] has reinforced **Harkness**'s view that the arthritis is identical with the arthritis sometimes associated with gonorrhœa (True gonococcal arthritis is very rare, it is suppurative, and gonococci can be found in the pus) This "venereal arthritis" is characterised by self limiting attacks lasting one to twelve months, with a tendency to relapse, the patient may be left with residual deformities of the feet and even ankylosing spondylitis, but rheumatoid arthritis is not a sequel. **Ford** found no evidence that antibiotics affected the course of the disease Corticotrophin or cortisone alleviated symptoms temporarily, but he was not convinced that fever therapy w effective This sombre view of therapy will not b shared by all clinicians **Harkness**,[23] for instanc claimed good results with oxytetracycline or aureomycin, combined with fever therapy Nevertheless many of the claims to have cured arthritis—often associated with eye and skin lesions (Reiter's syndrome)—must be viewed against the natural history of the disease There will be an understandable tendency to ascribe spontaneous remissions to any treatment Particular attention has been paid to pleuropneumonia-like organisms as a possible cause of the arthritis, because several species of this group are known to attack the joints of animals, but isolation of these organisms directly from joint fluids has only twice been reported, and there is at present no convincing evidence that th arthritis is due to such infection

Annotations

TECHNICAL ASSISTANCE

In 1949 the General Assembly of the United Nations made plans for an expanded programme of technical assistance to underdeveloped areas, and a fund was set up which could be drawn on by specialised agencies—the World Health Organisation, the Food and Agriculture Organisation, UNESCO, I L O, and others This fund has enabled these bodies to extend their work far beyond the resources of their regular budgets, and the expanded programme for the first three years has been working a budget of between 20 and 25 million dollars Duri the financial year of 1952, W H O had available, in cas or kind, a little more than 3¾ million dollars under th expanded programme [31], in the same year F A O disbursed 6¼ million dollars. The aid thus given ha been used to send expert consultants to poorly provided countries, to establish fellowships and scholarships, and to set up training and demonstration centres Equipment has not usually been provided, except when it was an indispensable part of other aid Assistance has been given only at the request of governments, and the recipients have had to match the U N aid with substantial sums from their own budgets towards the co of any selected scheme Often the local administrativ costs have been paid by national governments and i some schemes these have been as much as the U N contribution Both W H O and F A.O give figures to show that the aid which they give is no one sided charity, but that, in fact, U N is only helping those who are already genuinely setting about helping themselves Notable schemes financed in part by W H O, with technical assistance, have been the antimalarial work in the Terai region of Uttar Pradesh, in the foothills of the Himalayas, where 100,000 acres of jungle are bein cleared and a 30% increase in production of foods ha already taken place, the campaign to eradicate completely yaws from Thailand and Indonesia, and the setting up, in many parts of the world, of maternity and child-health centres, where local doctors, nurses, and midwives can be trained Since the inception of the programme, F A O have sent 624 expert advisers into the field, of whom nearly half have completed their mission, and 469 fellowships have been awarded to students, mostly from countries with limited facilities for postgraduate work

It is impossible to translate into dollars the value of th knowledge that has been distributed to needy countries in this way Nevertheless, the whole programme of technical assistance is threatening to fall to pieces for want of money Firstly the U N agencies only get their allotments on a yearly basis secondly, contributing countries have reduced their commitments and a 20% cut in all expenditure has had to be made No one who has examined the detailed reports of W.H O and F A.O would dispute that the funds have been well administered and almost all the money profitably invested in schemes likely to advance the health and economic prosperity of mankind. Underdeveloped countries are, after a lag, seeking to make the full possible use of available aid, so that requests for help now exceed resources Both in education and in development long term schemes are likely to do the most good yet, against an uncertain financial background the risk of starting something which may soon be cut off by budget restrictions is a real one. Worries of this kind may lead to the appointment of a specialist for a brief period to give immediate help in a particular plan when it would be wiser to recruit a man prepared for a longer stay and able to give detailed supervision to the whole project

There is no solution to these difficulties except a greater degree of financial stability Here the onus lies on public opinion in the contributing countries and it is disturbing to read [33] that the British contribution to this U.N work was cut from 2 1 million dollars in 1951 to 1 3 million dollars in 1952. This seems a trivial economy, and if other countries follow suit, the efforts to help the governments of the backward countries of the world to raise their people above primitive poverty will be seriously prejudiced.

A NEW ANTI-EMETIC

CHLORPROMAZINE hydrochloride (Largactil), a vigorous young near relation of the anti histamine substances, is so far best known in this country for its power to bring about artificial hibernation [34], and this action was discussed at a meeting of the Royal Society of Medicine reported on p 1294 of this issue On the Continent chlorpromazine hydrochloride has also given promising results in the treatment of psychiatric disorders. But its versatility does not end there; for it has a powerful anti-emetic action

Friend and Cummins [35] have treated seventy hospital patients with vomiting from such varied causes as uræmia, carcinomatosis and pregnancy and the effect of drugs such as aureomycin, morphine, and protoveratrine, and the disulfiram alcohol reaction The drug was given intramuscularly or orally in doses of 25–50 mg three or four times a day In almost all cases the vomiting ceased promptly and side-effects were rare, consisting only of mild drowsiness dryness of the mouth, and flushing Yet the other pharmacological effects of this drug suggest that its use as an anti-emetic will not long be untroubled by side-effects It is a ganglion blocking agent with anticholinergic and powerful sympatholytic and spasmolytic actions it acts on the respiratory centre, slowing the rate and augmenting the amplitude of breathing it blocks thermoregulation by a direct action on the hypothalamus, and possibly acts indirectly on the hypophysis, as is indicated by a modification of postoperative eosinopenia and it potentiates the action of many drugs notably the barbiturates, pethidine nitrous oxide, volatile anæsthetics, procaine amide, and curare.

The basis of anti-emetic activity in general has been much clarified by the work of Borison and Wang [36] These workers show that drugs such as apomorphine, to which have been attributed a 'central' stimulant action on the vomiting centre, do not in fact act directly on the centre The emetic response is now known to be carried to the centre in a reflex arc which is initiated at what has been called a 'chemoreceptor trigger zone.' This receptor is situated on the surface of the medulla outside the central nervous system and is activated not only by drugs but also by the vestibular stimuli concerned in the production of motion sickness.[37] The nature of the transmitter is not known, but it is apparently not acetyl choline.[38] If anti emetic drugs act—as conceivably they may—by blocking transmission at this site, it is unlikely that a specific anti-emetic will be found until the transmitter substance is identified Moreover Borison and Wang believe that the central vomiting mechanism cannot be depressed without concurrent depression of closely associated vital functions involved in the emetic syndrome. Borison and Wang give a conservative valediction 'The most intelligent therapeutic approach to clinical vomiting is elimination of the specific cause rather than the general effect'

SPREAD OF PROSTATIC CANCER

IT is well known that cancer of the prostate often metastasises to the bones of the vertebral column but how the tumour emboli get there is something of a mystery The normal channel of venous flow from the prostate is via the inferior vena cava, and it might be expected therefore that secondary growths would first appear in the lungs by arrest of emboli in passage through the pulmonary capillaries. It has been argued that minute emboli might sometimes be filtered through the lungs back into the systemic circulation and so reach the bones Certainly this might happen but a less tortuous route would seem more probable

Franks [38] has reinvestigated this question, taking as his starting point a suggestion by Batson [39] in 1940 that the prostatic veins and the vertebral venous system might be more directly linked. By an opaque injection method Franks has proved that there is a direct link between the prostatic venous plexus and that of the vertebræ and it seems from this work that the distribution of bony metastases in prostatic cancer can most reasonably be explained by the passage of tumour emboli along this channel, which by passes the caval, portal and pulmonary circulations.

Batson originally suggested that obstruction of the inferior vena cava by increased intra-abdominal pressure could predispose to diversion of blood flow from the pelvis into the vertebral venous system The possibility of similar factors in the distribution of venous emboli from prostatic cancer raises interesting practical questions. Coughing straining and increased intra-abdominal pressure from other causes may turn out to be dangerous to the patient with prostatic cancer

PRIMITIVE LEVELS IN SCHIZOPHRENIA

WHEN the nervous system degenerates, the highest levels of function being those acquired latest in the history of evolution perish first. Dr Ada Glynn [40] argues that a parallel process is evident in the decay of the mind in schizophrenia—that as disintegration proceeds primitive mental mechanisms appear and supersede rational thinking It is an engaging theory and she brings forward some well known ethnological findings to support it. Thus it is a common belief, in primitive cultures, that inanimate objects influence people and events. Such objects may be rocks trees weapons, leaves, animals—or words especially numbers and proper names The primitive tribesman, it is said does not distinguish himself sharply from the rest of the universe but believes himself to be constantly influenced by the objects around him and even by objects at a distance Again, primitive peoples often condense their ideas in picture images with more than one component thus a strong man may be represented as a combination of man and an animal (such as a horse) Ritual behaviour of a rhythmic kind is usually practised as a ceremonial. Magical properties are attributed to things, which resemble other things, and to things which have touched one another thus, a piece of coral resembling a bread-fruit is planted under the bread-fruit tree to make it bear better fruit, branches are waved to encourage the wind to blow, the arrow that has pierced an enemy is urned to make the wound inflame Their suggestibility s such that they have only to be convinced that an arrow is poisoned (though in fact it may have nothing deadly on it), or that an enemy has aimed at them with a ghost shot, in order to develop appropriate symptoms These primitive methods of dealing with experience, Dr Glynn thinks, can be recognised in schizophrenics Thus, patients complain of the harmful influence of neighbours and friends, without making any attempt to explain how these external influences act They attach great importance to words, often to neologisms, and seem to attribute magical properties to them, or to repeat them in order to avert disaster Often such neologisms are composite words condensing (like the centaur) more than one idea. Some patients feel compelled to repeat certain words, or think certain thoughts without, having any desire to do so Some refuse to answer to their names and insist on being called by others of their own devising Their stereotyped behaviour has the magical properties of a ritual and recovered patients can often recall the protective intent with which they practised such rituals Their suggesti-lity is indicated, Dr Glynn thinks, by the apparently ysterical symptoms—blackouts, tears, screaming attacks d the like—which are often the first symptoms of their sorder

She believes that if these regressions to archaic levels were recognised as such, and kept in mind, the diagnosis of early schizophrenia could be much improved. Three processes are at work mental disintegration, the uncovering of primitive mechanisms at the uncontrolled lower evolutionary levels of the mind, and the interaction between the disintegrated higher and lower levels The mental disintegration is responsible for the slow deterioration of the personality, the loss of interest in personal appearance with apparent apathy and loss of feeling, the loss of ability to concentrate and make decisions, the ambivalence in thought and behaviour, the fragmented conversation, the day dreaming and withdrawal The patient's difficulty in formulating thoughts leads him to pause long before answering a question, and accounts for the worried look so often worn by schizophrenics A common early symptom is unwarranted exaltation, manifesting itself as "a rising conceit with an ever declining performance"—evidence of the vagueness the patient feels about himself and his environment Impulsive behaviour often results from obedience to hallucinations, which are themselves partly the result of projection—one level of the mind accepting as bona fide sensory stimuli the imagery produced and projected by another level But hallucinations are also partly due to suggestibility, which is a characteristic not only of schizophrenic and primitive minds, but also of the mind of the child. Obsessional symptoms resemble schizophrenic symptoms, she holds, in being no longer controlled by those levels of the mind which have evolved later they bear the tamp she says, of magical thinking, and merely epresent another aspect of schizophrenia, even though he symptoms may never progress beyond the obsessional

While Dr Glynn's thesis is suggestive and it is not susceptible of proof at present—and indeed may never be Her confidence in its accuracy goe perhaps a little beyond the bounds appropriate to the detached scientist

NARCOSIS IN THE TREATMENT OF EPILEPSY

DESPITE new remedies for epilepsy, there remains hard core of patients who derive little or only temporar benefit from any anticonvulsant drug or regimen Their plight is sometimes made worse by the fact that their fit progressively narrow the field of work open to them For them, heroic measures seem justified, and they are usually only too willing to try these Putnam and Rothenberg[1] describe a method of "intensive treatment" for these patients it consists basically in narcosis induced with massive doses of hydantoins, supplemented, if necessary, by paraldehyde or phenobarbitone intramuscularly. The patients sleep for four days, and they are then roused by stopping all narcotics and giving amphetamine to shorten the period of awakening Depth of narcosis varies, but in general, continuous supervision and detailed nursing care, already familiar in the prolonged narcosis of psychi-atric treatment, are required Putnam and Rothenberg attach importance to the production of some degree of ketosis and to the intermittent inhalation of carbon dioxide They also give intravenous infusions of glutamic acid. Of 25 patients who had failed to respond to a very thorough trial of other remedies, 16 were rendered seizure-free for follow-up periods of a year or more, and a further 5 were substantially improved. All were maintained in this condition on the drugs, either in the same or smaller doses, which they had been taking without success before the "intensive treatment" These are impressive results considering the unhappy outlook for such patients at present

THE PARIS MEDICAL SCHOOL

ON Dec 3 the President of the Republic opened the new medical school of the University of Paris. It stands at the corner of the Rue Jacob and the Rue des Saints-Pères, on the site of the ancient Charité Hospital where Laennec used the first stethoscope

Building began in 1936 in the crowded area of St Germain des-Prés, and the austere, seven-storeyed school now dwarfs the picturesque and often shabby haunts of famous artists and writers But in Paris the humanities and science still know how to live amicably together, and the massive bronze portal by one of the leading masters may have meaning for some of the 2500 first and second year students who succeed in penetrating a growing doorway scrub of cars and autocycles Eight departments are already at work with the most modern equipment, the physics laboratories are insulated against sound and "les parasites électriques," and there are special facilities for radiology and work with radio isotopes. Lecture theatres have up-to date visual aids and physiology students can peer closely at the most delicate manipulations in the "amphi-théâtre lorgnette." Post-graduates have not been forgotten, and the Société de Biologie, with a long list of famous doctors among its past presidents, hopes soon to meet in the new school.

Dr THOMAS COCHRANE, who died on Dec. 7 at his home in Pinner, Middlesex, at the age of 87, worked a medical missionary in China at the beginning of the century and founded, at Peking, the first medical training college for Chinese students.

AT a meeting of the Royal College of Surgeons of England on Dec 10 it was decided to proceed at once with the building of the Nuffield College of Surgical Sciences.

With the assistance of MARGARET PETTS S R N

HE revival of interest in the possibility of preventing common cold and other disorders of the upper piratory tract by the control of airborne transfer of ction has uncovered the large defects in our knowledge he epidemiology of these diseases Before trying to ause trials of control methods we therefore made an demiological study of the incidence of colds and ilar affections among groups of office workers. Our was to relate the incidence of colds to certain ironmental conditions in an attempt to elucidate the de of spread. We here report the results of a pilot vey

With the help of Dr Cecil Roberts, then Deputy asury Medical Adviser we were able to invite the peration of members of the clerical staff of the General t Office working in a block of offices in the City of ndon. Each volunteer gave us detailed histories of or her cold' experience each week during the iod of the survey and at the same time we made ervations on the bacterial content of the office air d on the temperature and humidity in the offices.

Methods

COLLECTION OF DATA

After preliminary discussions with administrative icers and staff representatives a meeting was held to plain to the staff the plan of the survey and to invite ir help Questionaries were issued to each member the staff and were filled in by all those willing to take rt. These were checked for completeness by a nurse vestigator

The volunteers were enrolled in two stages From April, 49, 104 persons in three rooms A, B and C took part the survey In August, 1949 352 volunteers in ten her offices joined. Both groups were observed until pril, 1950 Altogether 92% of the staff volunteered. e intention was to question each person each week, t the second group proved to have a different system working from the first and consequently could only be terrogated once a fortnight. The difficulties of knowing hether a member of this migratory group was sent owing to sickness holiday or other reasons made e information obtained about them so unreliable that e results discussed below come almost entirely from the 4 staff in offices A B and C Of these 104 131 were esent for the whole year of the survey

METHODS OF QUESTIONING

Each week every volunteer in the static group offices A, B and C was questioned by the nurse about s or her experience of colds in the preceding seven days. Those who had had a cold were asked about their symptoms. Chronic coughs were ignored, but for l acute disorders a special questionary was completed giving details of symptoms on the day of onset recognised contacts with other sufferers from colds, possible predisposing experiences and so forth

The definition of a cold' is difficult, and in the present report we have grouped together under this term all minor acute respiratory tract disorders Virus influenza was not epidemic during the winter of our survey, and only about 22% of the incidents recorded were accompanied by symptoms of fever such as shivering The great majority (about 78%) were typical acute rhinitis, and most were accompanied by some soreness of the throat

Since it was clearly futile to try to interpret the frequency of 'contacts among those with colds without some knowledge of the relative frequency of such contacts among those free from symptoms a random sample of the remaining symptom free members of the same office were questioned similarly in the same week So far as possible, the numbers of 'controls' selected for interview were equal to the number with colds

BACTERIOLOGICAL AND ENVIRONMENTAL STUDIES

Visits were made to the offices once a week during the period May–October, 1949 after which it proved impracticable to make visits more frequently than once in two weeks. At each visit air samples were collected in eight to twelve of the rooms selected at random from the twenty four among which the volunteers were distributed, the order of visiting was also random

With a slit-sampler the bacteria-carrying particles from 200 c ft of air were collected on the selected medium of Williams and Hirch (1950) for the detection of *Streptococcus salivarius* and those from 5 c ft were collected on serum agar for a general bacterial count'

At each visit the temperature and relative humidity within the offices were measured. Outside temperature and humidity records were taken from the Registrar General s Weekly Return

Results

During the twelve months of the survey the mean number of colds reported by the 131 persons in rooms A B, and C who were exposed to risk throughout the whole year of the survey was 2 2 The numbers of persons reporting 0 1 2 6 colds in the year were respectively 13 26 40 36 11 3, and 2

We may consider first the factors associated with the individual that may have affected his experience of colds Secondly we may compare the experience of the groups of people in the various offices at different seasons.

PERSONAL FACTORS

The mean numbers of "colds per person among the relatively static population in the three rooms A B and C in each age-group and sex group are given in table I In the total' row and to a lesser extent among females there is a downward trend in incidence with increasing age There were only 12 males aged less than 50, hence it is impossible to judge if the same is true of males. The women had distinctly more colds than the men—

TABLE I—COMMON-COLD EXPERIENCE ACCORDING TO SEX AND AGE

—	Age-group (yr)							
	Under 30		30–49		50 and over		Total	
	No of persons	Colds per year	No of persons	Colds per year	No of persons	Colds per year	No of persons	Colds per year
Males	7	1 7	5	2 6	[illegible]	1 8	51	1 9
Females	36	3 0	22	2 1	[illegible]	2 2	80	2 4
Total	43	[illegible]	[illegible]	2 2	61	1 9	131	2 2

TABLE II—COMMON-COLD EXPERIENCE IN PEAK EPIDEMIC PERIOD 1949

—	Attacked 1–8 weeks previously	Attacked 9–26 weeks previously	Not attacked within preceding 26 weeks	Total
Exposed	48	36	63	147
Attacked in epidemic	17	23	30	70
Attack rate (%)	35	64	47	48

2 4 compared with 1 9—and this difference is not affected by age standardisation

There was also some evidence for short term immunity to the cold As will be shown below, there was a sharp epidemic of colds in the period Oct 29–Nov 19, 1949 Although only 131 people were under observation in the three offices A, B, and C for the whole year, 147 were observed from the beginning of the survey until the end of the epidemic in November, they could be divided according to their "cold" history in the months preceding the outbreak, and the attack-rates in three such categories of them are set out in table II The lowest attack-rate (35%) is among those who had had a "cold" in the eight week period immediately before the outbreak, the highest rate (64%) was among those who had had an attack earlier in the year but not within eight weeks of the outbreak Those with no history of previous attack since April had an attack-rate between these two (48%) The differences are technically significant, and a tentative explanation of them might be that those most susceptible to "colds" are distinguished by their previous history from the relatively immune, who have not been attacked for some time But in the epidemic itself there does appear to have been some short-term immunity conferred by an attack up to eight weeks before

TABLE III—HISTORY OF INFECTIVE CONTACTS GIVEN BY "COLD" SUFFERERS AND BY CONTROLS

History of contact with a "cold" sufferer	Persons with colds (363)		Controls (318)	
At home				
A*	9	56 (15 4%)	4	21 (6 6%)
B*	47		17	
In office				
A	2	45 (12 4%)	1	24 (7 5%)
B	43		23	
Elsewhere				
A	2	17 (4 7%)	2	5 (1 6%)
B	15		3	
None known		245 (67 5%)		268 (84 3%)

A*, contact recognised within last 3 days
B* contact recognised within last 6 days but not specified more precisely

PREDISPOSING CONDITIONS

Short-term immunity may conceivably be affected by predisposing conditions, such as chilling and fatigue An analysis based on the records of all the colds reported in the survey showed that the cold sufferers certainly gave a history of being chilled or fatigued significantly more often than the controls, but there were internal inconsistencies in the data which suggested that no great reliance could be placed on these findings

HISTORY OF CONTACT

Table III is based on all the 363 colds and their available con[illegible]ng both static and migratory groups It shows that a history of contact with other sufferers from a cold was obtained significantly more often from people suffering from colds than from their "controls" In the 32% of cold sufferers who gave a history of a recent contact with an affected individual, almost half named someone at home and half an office colleague These were the main sources of known contacts Even in these instances only 11% of the dates of contact could be placed within the likely incubation period of three days immediately preceding the onset of symptoms, and most cold sufferers could be certain only that contact had taken place sometime within the previous six days. This alone makes the linking of cases rather difficult, and it proved impossible to study the geographical spread within offices, because of the continual changes in siting of desks, jobs, rooms, and contacts

TABLE IV—FREQUENCY OF ATTACK IN DIFFERENT OFFICES

Office	No of persons	No of colds	Attack rate per person
A	44	100	2 3
B	18	40	2 2
C	60	145	2 1
Total	131	285	2 2

COMPARISON OF DIFFERENT TYPES OF CONTACT

Tables IV, V, and VI are based on the experience of the 131 people observed throughout the whole year Table IV shows that, within the range of average number of occupants here observed (18–60), there was no difference in the frequency of colds between people in the three rooms A, B, and C Nor is there in table V any evidence that, in these three offices, colds differed in their clinical patterns No differences could be distinguished in the timing of the epidemic in the three offices

We could not detect any material difference in the numbers of colds suffered by persons living with adults only, compared with those who lived in households containing children Those who lived alone had fewer colds, but their numbers were so small as to deprive these figures of any reliability There were no differences in the cold experience of persons travelling to work by different routes, but there were none who did not use public transport

SECULAR TRENDS IN INCIDENCE OF COLDS

The secular changes in the attack rate for colds in the three offices are shown in fig 1, where the smoothed curve of the number of colds per 100 persons per week shows that there was relatively little change in incidence during the early part of the autumn There was an increase to about 10% in early October, and then, in early November, a very sharp increase to a peak attack rate in one week of 24% The attack-rate fell sharply after this and, although it fluctuated somewhat, there

TABLE V—FREQUENCY OF VARIOUS SYMPTOMS IN 363 COLDS REPORTED FROM THE THREE OFFICES

Symptom	Room A	Room B	Room C
Sore throat	75 (63 0%)	38 (74 5%)	124 (64 3%)
Running nose	104 (87 4%)	44 (86 3%)	168 (87 1%)
Cough	57 (47 9%)	22 (43 1%)	81 (42 0%)
Headache	57 (47 9%)	29 (56 9%)	87 (45 1%)
Fever	26 (21 9%)	12 (23 5%)	39 (20 2%)
Other symptoms	17 (14 3%)	9 (17 7%)	30 (15 5%)
Total no of colds	119	51	193

s no further substantial rise in incidence during the nter

SECULAR TRENDS IN ENVIRONMENTAL FACTORS

The mean bacterial counts recorded in the air in the ces at each of our visits are also given in fig 1 The neral count fluctuated somewhat but showed no nsistent seasonal trend. The *Strep salivarius* count o fluctuated considerably, but there were three periods en it seemed to be consistently high in June and vember 1949 and in March–April, 1950 Owing to rather small numbers of samples examined these nations all need to be interpreted with caution

There was so little variation in the indoor temperature er the greater part of the investigation that the figures e not included in the diagram The outdoor temperature owed no striking autumn fall until mid October ring the last two weeks of October it fell from about °F to about 45°F The outdoor relative humidity o showed a sharp fall at the same time.

ASSOCIATION OF ENVIRONMENTAL FACTORS WITH PREVALENCE OF COLDS

It is immediately clear from fig 1 that the sharp drops outdoor temperature and relative humidity were closely sociated in time with the steep rise in the common-cold tack rate and in the *Strep salivarius* count in the air

he central heating in the offices was turned on gradually uring the period Oct. 25–28

The sharp increase in colds in early November was not ly simultaneous in the three rooms A B and C, and mong the migratory group in the office, but also general the London area. This was clear in the absence rate r a sample of Post Office workers distributed over the hole area (fig 2) Official notification of pneumonia in he London area followed the same time pattern after a g of about three weeks Fluctuations in the absence ate in the early months of 1950 were not, however, eflected in the common-cold attack rate in our office pulation.

Discussion

The study reported here was made principally to xplore a method of obtaining precise information on the number of colds suffered by a group of office workers so that their incidence could be related to environmental easures, including the bacterial content of the air For disease, such as the common cold, which is of variable verity and often does not lead to absence from work, tatistics of absence may be affected by morale in the

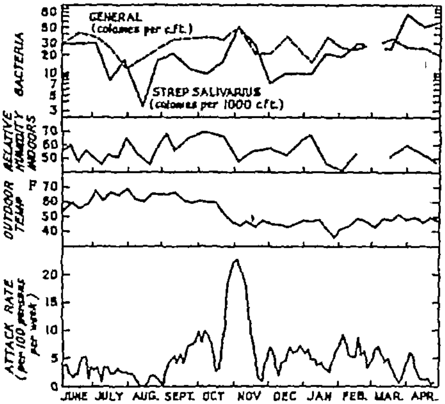

Fig. 1—Environmental factors and incidence of colds.

office, hence the number of absences does not necessarily reflect the number of colds suffered In our experience the number of attacks cannot be satisfactorily discovered by asking the subjects of the investigation to report only when they have a cold nor have we been successful in obtaining the information by circulating brief questionaries. The method now adopted of asking each individual personally each week whether he or she had had a cold in the previous seven days, has two major advantages: not only do we obtain a clear 'yes' or "no" for a period over which memory should be fairly accurate but we also have an opportunity of further questioning those who report a cold. From these supplementary questions one can assess more objectively whether or not the symptoms reported fall into the accepted definition of a "cold"

The success with which an investigation of this sort can be pursued depends very largely on obtaining the confidence of the participants In any large organisation there may be a fear that the results of an inquiry will be used in subsequent considerations of promotion or establishment. This is another reason for appointing a special investigator for the study and not relying on a member of the office staff for the collection of the necessary records.

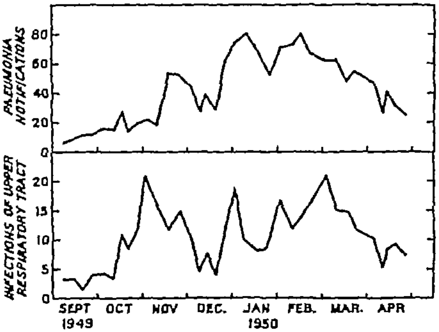

Fig 2—Pneumonia notifications in London and absence-rate per 1000 postmen.

Thanks to the coöperation of the staff in the department studied, we obtained complete detailed records of the experience of colds of 131 persons over one year. Unfortunately the duties of these members of the staff involved them in a considerable amount of movement, both within one room and from one room to another; so it was not possible to trace the spread of colds from one person to his or her neighbours at work.

Persons with colds remembered contact with someone else who had a cold more often than did "controls" who had had no recent cold. This may mean that, in some cases, the recognised contact was the source of the cold, but it may also be that persons with colds are more likely to recall contacts than are those without colds. Further, the fact that our controls were not strictly paired with the cold sufferers for age and sex might account for the difference. Even with these sources of error, only 32% could give a precise account of a contact.

We could detect no great difference in the attack-rate in groups of persons travelling to work by different methods, or coming from households of various sizes and composition. Nor in this urban group could we see the effect of the school child demonstrated in a rural group by Lidwell and Sommerville (1951). There was a suggestion, which in general confirms earlier observations, that the young women had the highest attack rate. There was no evidence that the size of the office populations was related to the risk of having "colds".

There was a suggestive time correlation between the onset of the sharp November outbreak of colds and a fall in both outside temperature and relative humidity; such a correlation was previously demonstrated by van Loghem (1928). During the same week there was a sharp rise in the number of *Strep. salivarius* in the air of the offices—an observation similar to that of Torrey and Lake (1941). A high streptococcal count was observed at two other times, but neither was accompanied by any rise in the incidence of colds in the offices. The association of a high streptococcal count with a high incidence of colds in November might be fortuitous, but if real it could be explained in one of two ways: (1) the onset of cold weather makes people shut the windows; this reduces the ventilation, increases the number of bacteria in the air, and may at the same time facilitate the spread of colds; and (2) alternatively the weather may precipitate the colds, and the sneezing and coughing they cause may lead to the rise in the streptococcal count in the air. Our present data do not allow a judgment between these alternatives, but other studies suggest that the *Strep. salivarius* count responds much less than the general bacterial count to changes in ventilation. The November outbreak was accompanied by little change in the general count; so diminished ventilation alone is unlikely to be the cause of the appreciable rise of the *Strep. salivarius* count.

The general picture of a sharp increase in attack rate over a short period suggests "epidemic" spread through the offices, but the fact that a similar rise in incidence was observed in many other offices in London throws some doubt on this interpretation and suggests that meteorological or similar factors may have been all-important. The elucidation of the part played by case-to-case transfer of infection within the office can only come from more detailed work than was possible in the present study. In particular it will be necessary to observe a group in which any individual's range of contacts is limited and well defined. Some studies of this sort are already in progress.

Summary

Members of the clerical staff of several offices in Central London were questioned weekly during the year April, 1949–March, 1950, about their experience of infections of the upper respiratory tract. 131 persons were observed for the whole year. On the average, each person had 2.2 colds in the year.

The incidence of "colds" appeared to be highest in young women. Although there was evidence of short-term immunity following a cold, no other differences in range of contact at work, in travelling, or at home appeared to affect the attack-rate.

The beginning of a sharp epidemic of colds in November, 1949, coincided with a sudden fall in outside temperature and humidity. At the same time there was a notable rise in the numbers of mouth streptococci in the office air.

Our thanks are due to all the volunteers who took part in this study. We are also indebted to Mr. D. E. Miller for technical assistance. The work was done on behalf of the Air Hygiene Committee of the Medical Research Council.

The Public's Health in 1952

In two years the death-rates in England and Wales among young women aged 15–25 have fallen by about a third. This striking change is mentioned by Sir John Charles, chief medical officer of the Ministry of Health, in his annual report for 1952.[1]

For this change the reduction in mortality from *tuberculosis* is thought to be largely responsible. In 1952 deaths from all forms of this disease reached a new low level of 10,585, giving a rate of 240 (respiratory 212, non-respiratory 28) per million population. Mortality from this cause has fallen 52% in the last four years. At the start of the year there were 290,389 notified cases of the disease; and by the end of the year the total had increased to 311,702. The number of new cases (all forms) diagnosed during the year was 44,525. About 1 in 7 of these was detected by contact examination.

"It is encouraging," says the report, "to note not only that the number of new cases diagnosed tends to become stable but also that greater and more fruitful use is being made of contact examination. In 1952 more than 8000 more contacts were examined than in 1951 and 4.64 per cent. of them were found to be tuberculous as compared with 3.5 per cent. in 1951."

Deaths from tuberculosis are now definitely exceeded by deaths from *cancer of the lung*, which numbered 11,218.

Two epidemiological features of the year were a further decline in the number of cases of diphtheria and an increase in notifications of scarlet fever. *Diphtheria* accounted for 376 cases with 32 deaths, compared with 664 cases and 33 deaths in 1951. The fatality-rate rose from 5% to 8.5%; in immunised children this rate was 1.1%, whereas in those who had not been immunised it was 9.9%. Cases of *scarlet fever* numbered 67,281 with a fatality-rate of 0.03%, compared with 48,744 and 0.08% in 1951.

Poliomyelitis.—In 1952, 3902 cases were notified, which was substantially below the average for the past five years. The fatality-rate of 7.6% was the lowest since the epidemic of 1947. Non-paralytic cases amounted to 20.8% of the total. Regarding control of spread Sir John Charles writes:

> "Certain simple general principles can enable us to lay down a course of action which is usually effective. Two of the most important of these are the isolation of the patient and the control of those individuals who have been in contact with him during the infective stages of the illness. The degree of isolation to which patients and contacts may have to submit varies a good deal with circumstances. In poliomyelitis the relevant circumstances which have to be taken into account are the ages of the patients and contacts and the amount of infection present in the locality. It has been noted time and again that outbreaks of poliomyelitis tend to occur in small communities such as

families, nursery schools, school classes or residential hostels. When an outbreak occurs in a day school it is usually the youngest children who are most affected by the virus. It is therefore logical as well as economical in effort to concentrate upon them the preventive measures available The measures most likely to effect control of the outbreak are the two general measures to which reference has already been made isolation of the patients and exclusion of their contacts from school for some three weeks.

Sir John observes that the number of incidents of *food poisoning* suggests that the gospel of kitchen hygiene has scarcely yet affected the practice of food handlers as a whole In 1952 5873 corrected notifications were received by the Registrar General but it is known that more than 11 000 people had symptoms. Altogether 3310 incidents were reported these comprised 372 outbreaks, 310 family outbreaks and 2807 sporadic cases. The presumed causal agents were *salmonella* (2008) staphylococci (82) *Clostridium welchii* (20) other organisms (17); and chemical (1) in 1301 instances the agent was not discovered Between 1949 and 1952 in 55–60% of all outbreaks where the vehicle of infection was established this was processed and made-up meat. In 1952 of all outbreaks (excluding family outbreaks) in which the place where the contaminated food was bought or eaten was recorded, 60 originated in canteens, 28 in restaurants, 19 in institutions, 16 in shops and 6 at private parties.

Venereal Diseases.—Once again at the clinics there was a substantial fall in the number of new patients with syphilitic infections of less than a year's duration: 881 men and 462 women attended for the first time in 1952 compared with 1408 men and 774 women in 1951 The number of cases of congenital syphilis in children under 1 year of age fell to 110 compared with 156 in 1951 Cases of gonorrhœa diagnosed in 1952 numbered 15,510 in men and 3585 in women compared with 14,075 and 3080 in 1951 The significance of this rise is not yet certain, but the possibility of a commencing strain-resistance to penicillin has to be borne in mind" Cases of non gonococcal urethritis in men numbered 11,562, compared with 10,704 in 1951

SOME MORTALITY TRENDS

Diseases of the circulatory system vascular lesions of the central nervous system, and cancer accounted for more than two-thirds of all deaths in 1952 compared with rather less than half twenty years ago. Deaths ascribed to *coronary-artery disease* again increased notably—to 61 420, compared with 40,330 four years earlier

The *stillbirth-rate* (23 7 per 1000 total births) has hardly changed since 1949 and the *neonatal mortality rate* (19 3 per 1000 live births) has likewise changed little since 1950 Sir John remarks

"It is an open question whether we have not progressed as far as our existing knowledge of causes and contributory circumstances can take us and that the way to further improvement lies through research, rather than through the continued exploitation or modification of established methods."

DENTAL TREATMENT

Between 1950 and 1952 the demand for dental treatment on behalf of young people up to 21 years of age rose from 18% to 20% of all applications. There was an almost equal reduction in the proportional demand by patients aged over 45 and the demand by those aged 22–45 remained about the same

UTILISATION OF HOSPITAL BEDS

Among the many other subjects discussed in the report is the utilisation of hospital beds.[2] This section includes a table (reproduced here) showing beds available for all physical conditions, excluding private pay beds, for each year since 1949

THE NEW PUBLIC HEALTH

Sir John Charles urges a fresh outlook on public health

"It has" he says, "been argued with some force that an increased expenditure on Preventive Medicine would *obtain a consequential reduction in the demands on the* treatment services. But to look at the matter realistically surely it would be courting disillusionment and disappointment simply to increase the financial support of the established forms of Public Health activity It is not enough to have more and more of the old remedies for the old ailments of the Public Health. Research in a number of new fields is required—into the causation of the so-called chronic diseases, into the manifold conditions which trouble the mental health of thousands of our fellow citizens, reduce their enjoyment of life and make participation in its tasks and responsibilities a struggle instead of an adventure; into the prevention of the trivial illnesses of everyday existence into the fostering of the physical forces of men and women so that old age comes upon them more gradually and with less sense of restrictive incapacity These are only a few of the comparatively uncharted fields, exploration of which will surely reduce the burden of the curative services.

Industrial Injuries Insurance

Papilloma of the bladder has been added to the list of diseases prescribed under the Industrial Injuries Act. The regulations[3] making this addition came into force on Dec. 7 They provide industrial injuries benefits for persons suffering from the disease as a result of certain specified occupations in which they have been employed at some time since July 5 1948 the date the Act came into operation Most of the occupations covered are in the chemical industry mainly in certain processes involving contact with α naphthylamine β-naphthylamine, or benzidine, or any of their salts. Cover is also given to workers engaged in the *production* of the dyes auramine or magenta there is nothing to indicate that the finished dyes are in any way harmful.

Scotland in the Third Quarter

In Scotland during the September quarter of this year[4] the birth rate of 17 3 per 1000 population was lower than the average for corresponding quarters in recent years, but it was the same as the rates recorded just before the late war The infant-mortality-rate was 28 per 1000 live births, which was 2 less than the corresponding quarter of 1952, 6 below the average for the past five years, and the lowest recorded in Scotland in any quarter The stillbirth-rate was 25 per 1000 total births—an increase of 1 over last year's figure The death-rate of 9 9 per 1000 population was 0 1 less than last year and 0 8 less than the five years' average. The death-rate from all forms of tuberculosis was 21 per 100,000 population (respiratory 18, other forms 3), the corresponding figures last year were 22 (19, 3)

CHOOSING AND CHANGING DOCTORS

P G Gray B Sc Lond.

Ann Cartwright B.Sc Lond.

From the Government Social Survey

The information given here was obtained in the course of an inquiry for the Committee on General Practice of the Central Health Services Council The inquiry was made in conjunction with the Survey of Sickness during February and March, 1952, and is based on 7027 interviews with a randomly selected sample of civilian adults covering England and Wales

Private and N.H S Patients

The people interviewed were asked whether they were on a doctor's list under the National Health Service, and, if so, whether they also received private medical care 97 7%* said they were on a doctor's list, 95 7% relying solely on the N H S, while 2 0% had a private doctor as well The remaining 2 3% were not on a doctor's list

Not all the 2 3% outside the N H S. relied on private practice, for some had not chosen a doctor because they had not been ill According to their replies to the question "what would you do if you were ill," they can be further subdivided The people interviewed then fall into the following five groups

	%
Registered under N H S and not using private practice	95 7
Registered under N H.S but also using private practice	2 0
Using private practice only	1 5
Probably will use N H S when ill	0 6
Probably will use private practice when ill	0 2

Thus in all about 3 7% obtained, or are likely to obtain, medical care outside the N H S

About the same proportion of men and women chose ~~to have a private doctor,~~ and the proportion rose only slightly with age Income was the most important factor influencing the use of private practice The proportion of people not on a doctor's list was small, and showed little change with increase in income, until the head of the household had a weekly income of over £20 a week, when the proportion was ten times the average for all adults

Each informant was asked whether he had consulted a general practitioner during the seven days before the interview, and, if so, whether the consultation was made under the N H S Of the 690 consultations made with general practitioners, 3 2%† were outside the N H S This figure gives some idea of the extent of private practice

Choosing a Doctor

5% of all the adults said that they had a woman doctor, but whereas 2% of men had a woman doctor, 8% of women had one The proportion of women choosing a woman doctor increased slightly with age —from 6% for women aged 21–34 to 10% for those aged 65 and over Thus women doctors tend to have higher proportions of women and old people among th patients than men doctors Both these groups tend make more use of their doctors. Thus, although medical profession is one in which women have pay, they probably do more than equal work for it

77% of men, as against 53% of the women, said th they preferred to have a man as a doctor. Most of remaining men, and 31% of the women, did not mi whether their doctor was a man or a woman. 16% the women, but less than 1% of the men, preferre woman doctor.

All informants were asked how they came to cho their present doctor. Only 1% gave the sex, religi or nationality of their doctor as the reason for th choice In 1% of cases he was a relative, friend business acquaintance A further 2% had first cal him in an emergency 23% had, as it were, inheri the family doctor 9% had taken over the husban or wife's doctor on marriage. 14% said they had re on recommendation These six groups, amounting half of the informants, may be said to have had so knowledge of their doctor before they chose him.

The remaining half gave reasons which sugge little knowledge of the doctor either directly or hearsay 15% chose the nearest or most convenien situated doctor, 4% took the only doctor availa 22% accepted the successor to a practice Most of rest could not remember how they chose their doctor

Changing Doctors

Informants were asked whether they had changed th doctor since the health service began, and if so reason for the change From their answers it is estima that the annual rate of changing doctors is abou per 100 adults in the service, but that four fifths of th changes are due to movement either of the doctor or patient The next largest group of changes, but o a tenth of all changes, is due to the patient's dissa faction with his doctor or with the treatment receiv Thus changes due to dissatisfaction amount to abou per 1000 adult patients in a year Smaller proporti of the changes were due to a wish for a doctor clo at hand, a wish to have all the family under one doct and a preference for a doctor of a particular sex, mai for a woman doctor

Patients' Opinions

When asked whether they thought the attention th received from their doctor was better or worse since health service started, only 16% of those on a docto list thought there had been any change Half of th thought it had changed for the better and half for worse Better attention meant in the main lon consultations and greater interest shown by the doct Worse attention meant the reverse About a third those who thought the attention was worse felt that doctor was not interested in them Rather more th another third felt that the doctor was too busy, had many patients, or, as one patient put it, was "too rea with the pen." Another appreciable group complain of having to wait in the surgery or that the doctor wo not call

Informants were divided into four groups according whether they were former panel or non-panel patie and whether they still had the same doctor as bef the health service or a different one In both group former panel patients a higher proportion thought attention was better The highest proportion, 1 was among former panel patients who no longer had same doctor In the groups of former non-panel patie more people thought the attention was worse rath than better, and the group of former non panel patie who no longer had the same doctor had the high proportion, 12%

---

* Standard error ± 0 3%
† Standard error ± 0 7%

SUMMARY

Of a sample of 7027 adults interviewed in February and March 1952, 97·7% said they were on a doctor's list under the health service, 95·7% relied solely on the service but 2·0% also used private practice. Of the remaining 2·3%, 1·7% were using or would use private practice while 0·6% would probably make use of the scheme if they became ill.

About half the reasons informants gave for choosing their doctor suggested that they had little previous knowledge of him either directly or by hearsay.

It is estimated that the annual rate of changing doctors is 7 per 100 adults in the service. Movement of patient or doctor accounts for four-fifths of these changes. About 7 changes per 1000 patients are due to dissatisfaction with their doctor or the treatment received.

84% of the informants thought that there had been no change in the attention given by their doctor (he was not necessarily the same one) since the N.H.S. started. Of the 16% who thought there had been a change, 8% thought they received better attention, 8% worse.

THE DISABLED TUBERCULOUS

Hostel and Workshop

The old chronic tuberculous patient with bacilli in his sputum, little social conscience, and no fixed home is an unfortunate person, besides being a risk to those who befriend him. He is apt to go short of both food and rest, the two chief essentials in his treatment. If he is in lodgings, and poor, he may economise by eating out as cheaply as possible, and he may also hesitate to spend too much time on his bed lest his landlady should suspect his trouble. If his only home is the common lodging house, he is usually not allowed in his cubicle between 8 A.M. and 8 P.M., and if, at night, he finds the house full he may have to tramp to another district to find a bed—a thing that often happens in large towns in winter. Dr W. Hartston (London) and Dr J. F. Macgregor (Middlesex) who draw attention to these hardships,[1] say that the homeless consumptive, especially if he is unable to work, or has diabetes, is doomed to a falling standard of care and nourishment, and they describe how his difficulties may be eased by the tuberculosis hostel.

Both London and Middlesex have taken advantage of the powers extended to local authorities to establish such hostels, which, as Hartston and Macgregor point out, not only increase the comfort of patients with advanced disease but also help to relieve congestion in chest hospitals (for few superintendents can steel themselves to discharge such patients on to the streets, and almoners can seldom find lodgings for them). Moreover, by providing alternative quarters for an infective uncle or grandparent, the hostels reduce the risk to other people, and especially to young children, who are living in the same household.

HOSTELS IN ACTION

The first hostel used by the London County Council for the tuberculous was opened at St. Albans in February, 1951, and was privately run. It had beds for 40, and during the time it was used for this purpose had an average of 36 men in residence each week. Later in 1951, however, it was found convenient to establish a hostel in Islington run directly by the L.C.C., and in September, 1952, some of the patients then in residence at St. Albans were transferred to this new hostel, while the rest went as temporary guests to Preston Hall.

The two roomy houses at Islington have so far survived demolition in an area scheduled for L.C.C. rehousing, and are not perfectly suited to their purpose, having many stairs; but they are airy, light, and welcoming. The walls of the rooms, painted a kind of golden toffee-colour, catch whatever sunlight is going and diffuse it. The bedspreads, too, are yellow, and the spacious bedrooms are not crowded, either with beds or furniture. Two or three beds to a room, set well apart, are the rule; but there are a few single rooms for those who prefer them; actually there are not many who do, for people liable to be ostracised are apt to favour a bit of company. Each man has a wardrobe of his own, simply but well made in natural wood, and a roomy bedside locker. He can use his bed at any time he likes, and many of the residents take an afternoon rest as a regular thing. A large billiards room equipped with a full-size table, and a plain but comfortable sitting room, both open by french windows on to a long balcony, overlooking the garden. Though the garden itself is disappointing (being at present rough and overgrown) it contains two well made chalets which are much prized by those residents to whom they are allotted; electric light and electric radiators make them comfortable even in winter.

A warden and his wife look after the residents and cook their good meals. The warden is a trained caterer and his wife has the maternal qualities the job demands. The dining room, plainly but pleasantly furnished with chairs of good design and several small tables, opens off the kitchen. There are separate sinks for washing up the crockery of patients and staff, and of course separate crockery. Soiled linen and blankets and bedding are disinfected by the borough health department before being sent to the laundry, and every newcomer has freshly laundered blankets given him from the linen cupboard. Bathrooms and wash basins are ample in number, and each hostel has a sluice for sputum disposal, fitted with a device for delivering a measured quantity of disinfectant into the man's pocket sputum flask.

The average number of men in residence each week in this hostel is 36. They may be any age, but there are just about as many between 40 and 60 as there are over 60; very few are under the age of 40. Since there are two houses (though they are joined, and have communicating doors at various levels) it has seemed a good plan to sleep the older men in one half and the younger ones in the other, and this suits both.

In July, 1953, a second hostel was opened by the L.C.C. at Fulham. This is run on much the same lines as the Islington hostel, and is also situated in a roomy private house—a very agreeable one, with a large and well kept garden, looking across a sports ground (and giving a fine view of the football matches played there). In many of the rooms the large windows stretch almost from floor to ceiling. Here too the equipment is plain and good, the food appetising, and the warden and his wife well suited by nature and acquirements for the job. This hostel can take 25 men.

MANAGEMENT

The residents in these hostels pay for their lodging according to their means, on generously assessed terms, but naturally the hostels are not self-supporting. Since, however, they have been established in existing houses and equipped simply (though well) they have not been excessively costly to set up. Hartston and Macgregor point out that though a hostel taking 40 or 50 may be more economic to set up than one taking 20 (which they consider to be the optimum) it is likely to be less successful because the staff will be too busy to make friends with the residents, who in turn—like the residents of other boarding houses—may then split up into hostile cliques.

---

[1] *Tubercle*, 1953, 34, 179.

The original idea was that one hostel should be for men going out to work, and the other for those not fit to do so, but as it turned out, very few of the residents were fit for work the demand comes mostly from those who will never be able to work fixed hours again Some pick up small sums selling evening papers, but this is hardly an advantage, for it may cause them to leave their hostel. His bed once booked in a common lodging-house, a man can go in at any hour (after opening-time) he likes, but hostels, staffed for daily living, have to have a closing hour There are few other restrictions the men come and go as they please during the day, and many of them go out. The aim of protecting others would perhaps be better fulfilled if some light occupations could be provided for them in the hostels. Lending libraries give plenty of discarded books, and billiards, and no doubt cards and dominoes, are provided; but few of the men seem to be readers, and games can pall An occupational therapist might be able to offer them more creative pursuits

A general practitioner acts as family doctor for each of these hostels, but if any of the residents need hospital treatment the local chest physician takes responsibility for them, and he has been given extra beds to help him to do so. There is naturally a fairly high relapse-rate. Applications for a place in a hostel come mainly from hospitals and chest clinics, and are sifted by the responsible officer of the local authority This is only fair, since applications come from a wide area, and there are not beds for all who come

Experience has proved that the hostels are needed, and are doing useful work at small cost The demand, in fact, is presumably far larger than the accommodation so far provided For a fairly dense urban area Hartston and Macgregor estimate it to be 5 hostel beds per 1000 tuberculous males.

A WORKSHOP FOR THE HANDICAPPED

A different type of help for men handicapped by tuberculosis is the sheltered workshop provided by Middlesex County Council at Tottenham Here a Civil Defence building, put up for decontamination of gas casualties in the late war, is being used to employ such men In every case the chest physician has given the opinion that they are not fit to do a full week's work The men are trained at the workshop as carpenters, joiners, and cabinet makers, and in six months become fairly skilled workers They are kept fully occupied by orders for equipment from the various county-council departments The standard of joinery is high, and the finish of the work both good and agreeable The main workshop is rather low, but light and airy A five-day week is worked, and of the 41 men now employed 2 began by doing six hours daily, but now do eight hours (a forty-hour week), 3 do seven hours, 23 six hours, and 13 four hours There are also 8 or 9 men in training, on grants from the Ministry of Labour All the trained men are paid a full week's wage at the minimum trade union rate for the job, even if they are able to work only a four hour day This frees them from any need to seek public assistance grants, and since their work must in any case be subsidised from public funds, it seems civilised to subsidise it in this dignified manner, which neither puts the man at a disadvantage with his fellow workers nor multiplies the activities of official departments Nevertheless it places a heavy financial burden on the local health authority It can be argued with some justice that the workshop is intended for men who will eventually be able to work 8 hours a day in sheltered surroundings and that there are plenty of such men about Many, however, live so far from the workshop that the journey would be too much for them clearly a workshop of this [illegible] only serve a limited area. Those admitted to [illegible] are carefully selected by the chest physician from patients—most of them still sputum-positive—who have completed their treatment but are no able to undertake full-time work, anyhow for some They are fit, however, for employment under conditions, and not at high pressure, and many of within six months or a year become able to work 40-hour week and keep well The selection of patients is not easy, of course, and some of the not progress as well as was expected. A few fit for more than 4 hours' work a day, and it might argued that sheltered employment was never for these But their state of mind and general improve, and they are better off doing part-time than they would be suffering idleness and boredom the lower standard of living which are the lot of those National Assistance grants. Those who work all day are no better pleased than the labourer in the parable to see those who have done less getting the same pay and human nature being what it is, there is a tendency for men who are getting full-time pay for working half time to show no enthusiasm for working longer hours for the same money It is difficult to find an ideal solution to the problem The answer seems to be additional work shops of the type that cater only for part-time employees but the establishment of these must naturally take second place to workshops for those fit for full time work

The reablement and sheltered employment of people handicapped by pulmonary tuberculosis deserves to be considered as responsibly as treatment of the disease it is part of the general management of patients suffering from tuberculosis, not a service that can be run at a profit The heavy financial subsidy brings valuable returns, none the less, for sheltered employment keeps infectious patients from having to seek employment in the open market, where they are a continual source of danger to their workmates, and—by raising the standard of living—helps members of their families to resist infection

The Tottenham workshop certainly reflects great credit on Middlesex It was begun in a small way in an occupational therapy unit, where it struggled on in awkward quarters until it had proved its worth When the county council provided the present workshop, in 1948, the plan was to employ 24 carpenters, and two additional groups of workers—shoemakers and sempstresses—who could have been accommodated in the same building Though this scheme was never approved the woodworking scheme was extended, and the workshop is now allowed to take up to 52 carpenters and cabinet makers

The relapse rate among these men is high, as might be expected in view of their serious disability but most of them return to work again after further treatment

Of 69 trained and employed during the four years between Sept 1, 1949, and Aug 31, 1953, 49 are still employed in the workshop, 1 has graduated to full time work in open industry, 3 are in other employment (1 in his own business, 1 as a male nurse, and 1 in a Remploy factory), 6 have left because of permanent sickness, 4 are in hospital, 5 have died, and 1 has been discharged as unsuitable.

Of the 49 now employed, 10 have been in the workshop for over 4 years Only, 14 have had bouts of illness lasting more than 4 weeks Their sick pay is generous. they receive full pay for the first month, and full or half pay, according to need, for the next 3 months, after that they go on National Health Insurance

In one respect the incidence of illness among men is reduced. they show none of the depres anxiety, and apathy so common among disabled men they are *not* employed. Much of the credit for the hap atmosphere of the workshop, as well as for the standard of craftsmanship, must go to the instruc manager, Mr W R. Osment

The Widdicombe File

V FORWARD MARCH

DEAR PETER,

I am anxious to come up and talk surgery Can you put me up next week ?

Since we last met I have bought a *forty-acre* moor land farm in Devonshire from which I am writing to you today I have two more years on the Hospital staff When I retire I hope to retain enough private practice to pay the rent of my flat and consulting rooms for another five years. Meanwhile I intend to spend my holidays and most of my weekends down here preparing a home in which to spend my dotage.

Conditions are primitive. The farm house has three rooms on the ground floor, tiled, and heated by a huge open wood fire The stair to the upper storey is more like the ladder it replaced than a real staircase The basins in the bedroom and the bath in the scullery are filled from jugs, and the waste runs into the yard The lavatory is an outside earth closet Water is pumped by hand from a well. Lighting is by paraffin lamps and candles.

Living under these conditions is Spartan but reassuring I know that every device ministering to my needs has been tried and tested by centuries of constant use. The walls will stand any shocks short of atomic explosions. There are no drains to smell or get out of order There are no pipes to freeze in winter Coal strikes will leave me undismayed. Electric failures will not affect my cooking or my illumination My water is safe unless I foul it myself and it never stinks of chlorine. My milk comes from a cow rather than from a tank in which the yield of two thousand cows, refrigerated and chemically protected, has been carried by lorry from country to town, graded, sorted and bottled and sent back again to the country My eggs were laid by a European hen My butter owes none of its colour to dyes and none of its freshness to preservatives I shall spend the next five years bringing the house up to date, but shall I be any better off when I have finished ?

Science has advanced more in the last twenty five years than in the previous two thousand. So we tell ourselves, but sometimes when large transport-planes drone overhead, disturbing our sleep and dropping blocks of ice on our greenhouses, or when political vans parade down our streets bellowing like sea-lions at feeding time and making work and even thought impossible we wonder if advance and progress are necessarily the same thing The old fountain pen which we filled by unscrewing the top and running in ink from a glass filler never leaked and would write for a week without replenishment the modern balloon reservoir pen spoils all our waistcoats and will seldom write more than five or six hundred words without refuelling The pre-war motor-car was not so fast as the black beetle that has replaced it, but it went and went on going for years, and it had two accessories that were worth more than all the gadgets of today—a hand brake that really held it on a hill while one wheel was jacked up for a tyre change and a hand throttle that allowed the driver to adjust the engine to a nice tick over and to rest his tibialis anticus on a long drive Even the wonders of modern anæsthesia pall at times, and the surgeon wishes he could go back to the bottle and mask and an abdomen to which the guts could be returned at any rate till the peritoneum was closed.

* * *

I am proposing to visit you because I want to see you do some prostates. In London we all do the retropubic operation In the North you all do the transvesical But in both places each surgeon has his own modification of the Millin or the Wilson Hey How much is there in all this ? How much better are these modern methods than Horner s operation as performed by Freyer ? Sidney Macdonald did the Freyer operation unvarnished and unmodified till he died and I doubt if any surgeon today has a lower mortality or gets better functional results You now work by direct vision and use diathermy and you probably have a cleaner and drier field at the end of the operation. Do you think there is much in it ? You poke your catheter down the urethra from bladder to meatus and think you are keeping out bacteria thereby ' Kind hearts are more than coronets, and simple faith than Norman blood ' You are able to close the bladder ; but is that because you do a better job than Freyer or because you knock hell out of your house-surgeons ? In Freyer's day they slept at night now after a urological afternoon they must abandon sleep and girl friends till the last clot has been washed out. You no longer fear to operate in acute retention, and that is a real advance but surely blood, chemo therapy, good anæsthesia, and good sales talk will account for the rest.

* * *

Surgery has certainly changed in our time When I came to hospital, the last of Lister s pupils had just gone off the staff, but antisepsis was still a religion and germs were still looked on as evil Every ward had an alcove in which were stored antiseptic solutions and dressing materials Glass cisterns containing solutions of carbolic acid 5% perchloride of mercury 2% lysol 2%, and a saturated solution of boric acid (coloured pink blue yellow and white) stood on the shelf and below them were glass jars containing pads of sterile gauze iodoform gauze and sal alembroth gauze (white, yellow, and mauve) Ward dressings formed a great part of our work Clean stitched wounds were dressed daily If they remained clean the stitches were removed after a fortnight ; if not they were put on to four hourly hot boracic fomentations after removal of alternate stitches Septic wounds were dressed morning and evening, and sometimes four hourly Tubes, of which there were often several, were removed and boiled at each dressing the tube track was syringed with an antiseptic lotion till it was clean and the tubes were then reinserted

In the theatres gowns and towels were sterilised in the autoclave, but instruments, after being boiled were kept in an open tray of lysol Some surgeons worked with bare hands and scorned masks, but the majority wore masks and boiled gloves. The seniors of that day were expert anatomists but having served a long apprenticeship in the dissecting room and having been denied access to beds, except during holiday time till they got on the senior staff, they had never acquired skill with their hands. With two exceptions, the men on the surgical staffs of the London teaching hospitals up to the first world war were bad operators by modern standards —far inferior to the surgical registrars of today

You joined the R.F C while a student and when you came into the wards in 1919 you found a very different picture Four years of war had shifted the emphasis in wound infection from the attack to the defence, from the bacteria to the resistance of the tissues In the theatres dry sterile materials were the rule and dry sterile gloves had replaced wet ones. Emergency work included acute appendices and the accidents of dock and factory but those commonplaces of pre-war ' take ins, the strangulated herniæ the extravasations of urine, and the late appendices admitted with general peritonitis, were already becoming rare Most of the patients coming from the theatres to the wards had clean stitched wounds covered with sterile dressings over which were many layers of sterile wool and voluminous bandages, and these dressings were retained till the stitches came out The coloured lotions and the coloured gauzes had disappeared and the only antiseptics in common use were flavine and Dakin s solution

A younger generation of surgeons, trained to operate in the casualty clearing stations, and taught to look on clean dissection, gentle handling, and accurate hæmostasis as the chief safeguards against infection, had taken over and were setting a new standard Rapid operating was no longer regarded as the hallmark of surgical skill, but on the other hand an operation lasting much over an hour was a thing to be avoided Anæsthesia was emerging as a specialty, but pink ears and a relaxed abdomen were still the exception rather than the rule

* * *

Nowadays we are a bit too complacent about surgical advances From 1870 to 1915 things really did move Victorians imbued with the spirit of the Elizabethans, gay adventurers armed with weapons of a potency hitherto unknown, hacked their way through an unexplored jungle to discover lands of rich promise From 1915 to 1935 their successors cultivated the land so hardly won, brought it into production, and extended its territory Since 1935 further advances have been made we have seen a steady improvement in the scope of surgical enterprise, in the increased safety of surgical operations, and in the diminution of postoperative morbidity, but I don't think that we surgeons can claim any of the credit The surgeons of 1920 were better than the surgeons of 1910, but I don't think that the surgeons of 1953 are any better than those of 1920—than men like Gordon-Taylor, Charles Saint, John Fraser, Richard Charles, and many others who worked behind the lines in 1917 and 1918 On the other hand, surgical environment, surgical method, surgical equipment, and surgical auxiliaries have improved out of recognition Continuous intravenous administration—the basis of planned resuscitation and of all supportive and postoperative therapy—was introduced in 1925 only, and reached England in 1930 Gastric suction appeared about the same time, and intestinal decompression followed later The physiological outlook that abolished purgation and starvation, that brought the study of fluid and salt balance, and that taught the dangers of postoperative immobility, was a result of the break with tradition and the rational outlook that came of the first war Chemotherapy first appeared in 1935, and was not in effective use till 1940, while penicillin came three years later

The position of surgery today depends more on the improvements that have taken place in anæsthesia than on anything else Men like Macewen, Trendelenburg, and Arbuthnot Lane advocated operations on the lungs and heart half a century ago, and Sauerbruch played with his differential pressure chamber thirty years ago, but it was not till the advent of closed circuit anæsthesia and controlled respiration that pulmonary and cardiac surgery became a reality

Just watch that patient on her way back to the ward after a mitral valvulotomy (How I wish that our thoracic surgeons, brilliant and lovable colleagues as they are, were not so careless with their language We should shudder if a gynæcologist talked of cæsariotomy, or a physician of renitis, yet we allow this bastard offspring of two noble languages to defile our literature "Valvulotomy"—ugh! "Valvotomy"—even worse The valve is one of nature's inventions applied by man to his own uses from the earliest times, and the Greeks certainly had a word for it Epistomion has a pleasant ring about it, but I am told at Balliol that it does not occur in the classical period Sandon is better Let the International Society of Thoracic Surgeons, when they next meet in Buxton, Stockholm, Locarno, Hot Springs, Santa Barbara, or Buenos Aires, table a discussion on the relative merits of epistomiotomy and sandotomy as the first item of their agenda, and, having made their choice, apply for readmission to the ranks of the educated)

We shall have to run down the stairs to catch our pat[illegible] the bottom of the lift She looks as if she had just woken from a pleasant sleep Her eyes are brigh her breathing is quiet, her skin is warm and dry, and sl has just started to chat to the nurse who is seeing h back to the ward Her wound is covered only by a str of gauze held in position with a few bits of strappin Soon she'll have a cup of tea Tomorrow she'll be sittı in a chair In five days' time her stitches will be ou and in ten days she'll go home Yes Peter, surgery h changed in our day

* * *

Personally I'd say that the most important improv ments of the last five years have lain in receding fro the advances of the previous ten The radical surge of malignant disease of the pancreas has been foun except in ampullary growths, to shorten rather tha prolong life and to make the end more miserable Vag tomy, the vaunted cure of peptic ulcer five years ag is now a thing we had rather not talk about The surgic removal of prolapsed intervertebral discs has bee found, on the whole, less satisfactory than treatme by manipulation or by a spinal brace Sympathet operations for hypertension have proved unnecessa in early cases and useless in late ones, and they survi merely as an occasional palliative to relieve intolerab headaches and failing vision Shunt operations for port hypertension have hitherto escaped debunking, but the are in urgent need of it

But ground is also being won that will never be lo again The surgery of mitral stenosis, the surgery coarctation, the grafting of arteries, these will remain and next week when we come back from the prosta session to a good dinner and a glass of port we sha remember others At any rate we shall thank our sta that we have spent our lives in a job that can never standardised or planned on mass production lines.

Your old friend,

DANIEL WHIDDO

Parliament

QUESTION TIME

Myxomatosis

Replying to a question Mr G R H. NUGENT, joint parli mentary secretary to the Ministry of Agriculture, said th in the past four weeks 5 fresh outbreaks of myxomatosis wild rabbits had been confirmed. There were now 3 centr of infection in Kent, 2 in East Sussex, 2 in Essex, and 1 East Suffolk The most recent outbreaks were in Esse East Suffolk, and Kent There had been no appreciable loc spread of the disease at the existing centres of infectio About 800 rabbits were known to have died of the disea since it was first reported More infected rabbits might hav died in their burrows either from the disease or gassing

Mr SOMERVILLE HASTINGS What are the latest ideas to how the disease is conveyed? Is it by birds or by huma beings, or only by direct contagion? Mr NUGENT I thin it is probably conveyed by direct contact between the rabbi and by insects—probably to some extent by birds as wel but mainly by insects in the spring and the summer

Mental-hospital Nurses and National Service

Replying to a question, Mr H. A WATKINSON, parli mentary secretary to the Ministry of Labour and Nation Service, said that student nurses in mental hospitals we not exempt from National Service, but their call up could deferred until they had completed their training

Sale of Condemned Meat

In answer to a question, Major GWILYM LLOYD GEORG the Minister of Food, gave the following summary of th revised conditions for sale of condemned meat

> Condemned meat and offals bought at auctions from Govern ment slaughterhouses must now be processed boiled, or sterilis before re sale Where the meat is re-sold to a retailer for anima feeding or to a processor the liability for processing boilin or sterilising must be included in the contract of sale Sellers o raw condemned meat and offals must inform the medical officer o health in the area where the meat is delivered of the names an addresses of the consignees

In England Now

A Running Commentary by Peripatetic Correspondents

GETTING out of the United States is so absurdly simple, compared with getting in, that it almost gives the impression that nobody cares. To get *tecsticards* across the Atlantic requires quite a lot of effort. Passport (with photos of course), vaccination (certified) visa (more photos) a personal interview and a lot of questions connected with MacSomebody's Act,' monetary arrangements and so on Two lots of immigration officers came on board in the St. Lawrence River and took a real interest in our dossier With characteristic kindness and clarity they wished us a good trip and *cautioned* us on no account to part with the visa papers until we left, implying that these represented our only hope of escape. It did *not*, however work out that way at all. Warned by the shipping people of something formidably called a ' sailing permit,' we had visited the income-tax offices and with courteous help filled in a lot of details revealing our relative lack of earning capacity in the States. The time of departure arrived. This was the moment when another kind official would surely scrutinise us for the last time ask after the trip and with some ceremony remove our visa papers and sailing permits. So when the baggage had been sent on its way from the taxi to the ship (and no examination of that either) we looked around for the aliens this way" notice There wasn t one A dock-side cop suggested that our passport business would be taken care of on board so on board we went. There was still no sign of the U.S government The chaps (and girl) in the purser s office were quite amused. " Oh no ! " they said, ' *they* aren t interested any more. So our sailing permits went into the garbage box in the cabin (sorry—British ship—wastepaper basket) and the visa papers into ditto after the purser s assistants had ripped them out of the passports. It really hurt a little Nobody cared.

The philosophy is probably simple and logical, like most things in the States. No decent sort of person could possibly want to leave such a pleasant land and nothing must be done to hinder the departure of the other sort. So the absurd traffic light at the end of the dock changed from red to green and the big ship backed out unailed exactly at the promised sailing time Not even the first respectable cup of tea for five weeks quite removed the feeling of anticlimax. Perhaps MacSomebody-or-other should give the matter a little attention.

* * *

I have lately been able to neutralise two nuisances of modern life, and as a small contribution to sociology if not to science I have decided to publish my method

A so-called friend thinking no doubt to confer riches upon me in the modern manner lately divulged my name and address to a football *pool* The result has been a monotonous and unwanted weekly envelope packed with esoteric forms. I examined the first packet but found the problem beyond my mathematical capabilities All subsequent envelopes went to swell the family salvage collection.

My small son is undergoing the early processes of education Inheriting no doubt paternal tendencies, he was advised or more likely instructed, to practise writing (both letters and figures). This means that someone and there is an obvious choice, has to rule paper for him. With a chipped ruler this is at best, a tedious operation.

An idea of staggering brilliance brought together these two nuisances. The football pool forms provide a ready-made page regularly divided into lines, columns, and squares eminently suitable for guiding the letters and figures of a wavering childish hand. And who knows if I ever post back one of the completed forms, it might yet fulfil its intended destiny

* * *

Rabbit-keeping is very traumatic to the parent. Our numbers vary from day to day, though my two children merely own two males (Cottontail and Parlicoot) The total group, two harlequin Dutch a white angora, a rabbit-coloured angora, a grey fierce plushy type, and my own two Belgians increased in two weeks by 16 babies, but an epidemic has appeared in the three-*month-old ones. They just fade, and I,* as a doctor in the house, am shown the corpse in the incinerator I have not done a post-mortem and I have listened gravely to all the ætiological views. Our authority up the hill on the small holding says it is poisonous weeds, and the youngest scapegoat is blamed My friend in general practice says it is overcrowding, and the man in Boots veterinary department says avitaminosis (B) Rival rabbit-owners accuse one another of neglect, and wilful starvation. My two children madly increase the living-space, provide lashings of water, and obsessionally sort the bunches of fresh grass for poisonous weeds.

In spite of all this, Parlicoot was obviously sickening when we returned from our evening session. He was cold not eating respirations shallow and slow, had lost his plump glossiness and felt like a bag of bones. After consultation with my senior colleague we plumped for a virus infection, and, failing all else introduced five minims of topical chloramphenicol orally Within three hours we heard a reassuring grind of teeth from the hutch at the foot of our bed We gave him two more minims for luck and in the morning he actually licked it up He convalesced, more or less, in my son s arms and after 18 hours had an ecstatic reunion with Cottontail. On Thursday the rabbit-coloured angora was dead, and his brother comatose. We put him on to chloromycetin at once. After each of the first two doses he regained consciousness, but during the third dose he lay in opisthotonos and apparently died As I left my daughter rushed up Mummy, the children say the one in the incinerator is moving ' I shut the car door on myself deliberately Grandly, but with a craven heart, I said ' Tell them I say he is dead ! '

Parlicoot was a bit inflated last night. We feared liver damage with ascites, but it was only wind

* * *

If you dine at any of our more expensive restaurants you will almost certainly find that the waiter will bring your change on a plate The plate is usually taken from one of the tables, and after you have clawed the coins from the slippery surface and left an appropriate residue for the waiter you will see the empty plate duly restored to the table The experience always makes me a little uneasy about the plates I have used.

At a hotel where I dined last week I plucked up courage to mention the matter to the waiter The man was evidently a foreigner and for a few moments he looked puzzled. Then the kindly light of reason shone from his eyes and he exclaimed—to the great delight of the guests at the tables nearby— Ah yez, now I understand Zee plate—zee jairms—veree bad Yez, I send 'im back to kitchen for wash ! '

My objection to the practice is æsthetic. I am prepared to hear from some *learned* bacteriologist that coins are no dirtier than the waiter's hands—and no cleaner Indeed it might turn out that coins provide a poor culture medium for bacteria. Perhaps the minute amounts of metal combined with the animal proteins of sweat, sebaceous secretion, and epithelial debris lying on the surface are ultimately fatal to most micro-organisms. But I still think that if the waiter were to drop a handful of coins into the bacteriologist s broth he would send it back to the kitchen

* * *

When my five-year old daughter came home from school singing the following song I realised that modern education has not yet caught up with the National Health Service

Miss Polly had a dolly who was sick, sick, sick
So she sent for the doctor to come quick quick quick
The doctor came with his bag and his hat
And he rapped on the door with a rat tat tat
He looked at the dolly and he shook his head
He said Miss Polly put her straight to bed "
He wrote on a paper for a pill, pill pill.
" I'll be back in the morning with my bill, bill, bill

At the end of the song she looked at me with a puzzled expression and said Mummy, do people have to *pay* doctors ? '

Letters to the Editor

THE TELESCOPE IN MEDICINE

SIR,—More than ten years have elapsed since John Ryle became the first professor of Social Medicine in this country Yet we still find the terms Social Medicine and Public Health being used as though they were synonymous The two subjects are frequently linked together for teaching purposes and their subject matter has much in common There is, however, a fundamental distinction between them, for Public Health is essentially part of medical practice whilst Social Medicine is a highly specialised branch of medical research

It is not surprising that in his short term of office Professor Ryle should have failed to produce a convincing definition of the subject For he was setting out to break new ground and had been saddled with an awkward title If, however, contemporary workers in this field allow the profession to assume that they are merely attempting to widen the horizons of medical practice they may endanger the future development of that part of medical theory which is concerned with the study of causative agencies

The study of ætiological factors in medicine is a vast subject In the remote past it was the sole prerogative of clinicians, but in recent years the most valuable contributions have come from the laboratories For, unlike their predecessors, laboratory workers possess tools which have enabled them to identify in particular diseases the (usually minute) causative agencies which are common to every case By concentrating on these they have also uncovered two facts of the greatest importance to medical theory First, that the universal agencies are rarely, if ever, the sole cause of disease, and second, that not all the persons exposed to their action become ill It follows that causative agencies exist which are not common to every case of a particular disease

At first sight this suggested that every case of disease was unique , and if clinical work had not already shown that a significant proportion of affected persons had other things in common the theory of uniqueness might have been accepted As it was, many long suspected genetic and environmental associations had been confirmed by clinical research and new ones were being added to the list of suspects To discover the nature of these accessory agencies new lines of ætiological research were developed In this field also the experimental method proved remarkably successful and to this we owe, for instance, the theory of innate and acquired immunity to infection We must, however, face the fact that there are in the accessory class two types of causative agencies—those which can be investigated in the laboratory and those which cannot The former resolve themselves into the study of certainties and the latter into the study of probabilities

This distinction is an extremely important one, because to make *precise* estimates of probabilities it is not enough to note that certain types of person more often present themselves for treatment than others *That is to say, the ætiological problems which do not lend themselves to experimental investigation also lie outside the usual range of clinical investigation* It is this challenge which is today being met by the new departments of Social Medicine Their methods involve the isolation of groups or populations defined by the genetic or environmental influences which it is proposed to study The behaviour in certain respects of these and control groups is then followed and significant co variants are identified by making statistical comparisons

The division between Social Medicine and Curative Medicine, and the essential links with group studies and statistics, probably account for the present tendency [illegible] it with Public Health For the older and better known subject is concerned with prevention rather than cure it serves the community rather than individuals, and it involves the collection of statistics It is not, however, called upon to use statistical methods as a research tool

Once it is recognised that the new subject is not concerned with medical practice but with the underlyin theory, its position vis à-vis other branches of medicin can be more clearly seen Clinical Medicine and Public Health then appear as partners, the former providing a curative service for individuals and the latter a preventive service for the community Behind them stand the Experimental Medicine and Social Medicine teams, each providing a quota of facts and theories on whic the practitioners base their respective policies

Needless to say, out of the practice of medicine new knowledge is constantly emerging, and in the workshops of medicine many practitioners are employed Nor is this free interchange of work and ideas the only reason why it is difficult to keep certain distinctio clear In medicine, above all things, the provision of service with wide and ever-extending ramifications ha had to take precedence over everything else So incessant has been the demand for practitioners that it is only comparatively recently that the profession has been able to carry whole time research-workers The original corpus of medical theory was created and maintained by physicians and surgeons whose busy practices d not prevent them from making careful studies of thei material and recognising essential links between their diverse observations The clinician still has a unique rôle to play in medical research, but today it is possible to supplement naked eye observations with those made with special instruments On the one hand there are the microscopic methods of the laboratory workers and on the other the telescopic methods of Social Medicine.

The latter has so many things in common with astronomy—the wide range of observations, the focus on distant objects, the rigidity of the universe observed, and the dependence upon mathematics—that one is surprised that no pioneer ever drew the analogy Had he done so the founders of the Oxford chair of Social Medicine might have hesitated before selecting their title The one they chose obscures that fact that th subject is a branch of fundamental research and (by suggesting a social service) has given rise to false expectations It would indeed have been better to have done as Cambridge has and omitted both the word social and the word medicine But the Cambridge title, Human Ecology, is still unsatisfactory Its implications are to wide , it fails to show the relationship with medica science, and it gives no indication of the basic methodology Since the subject is solely concerned with ætiological problems the term ætiology should appear in the title, qualified—for it must be distinguished from experimental and clinical studies—by the adjective statistica

ALICE STEWART

LACTIC ACID IN THE TREATMENT OF OSTEO-ARTHRITIS

SIR,—Though Mr Waugh (Nov 21) and Dr Vergett (Nov 28) have made some valid criticisms of the conclusions reached in my paper, I do not feel that they are such as to convince me of the value of this remedy. Mr Waugh is of course correct in saying that what the trial proves is simply that among miners and wi the technique used, lactic acid has no therapeutic actio in osteo arthritis Nevertheless, while recognising Mr Waugh's much wider experience of the technique involved, I would question whether osteo arthritis in miners really responds so very differently from the same disease in others If this is so, it is surprising th negative results were also obtained by Desmarais in t ath area where coal mining is likely to be a less frequent ource of livelihood

Mr Waugh's criticism of the absence of statistical nformation on the value of physiotherapy is certainly ully justified, but it is hoped that work in progress at resent will remedy this deficiency

Dr Vergotte has implied that physiotherapy may in ome way neutralise the effect of lactic acid. If this is o, the results of a trial comparing untreated patients ith those receiving lactic acid should, as he suggests rove very informative Until he has produced uch results, however we must, I think consider the alue of lactic acid at least doubtful and certainly mproved

Manchester University
J S LAWRENCE

OPERATING THEATRE INFECTIONS

SIR —After reading the report by Dr Sevitt and your leader (*Nov 28*) *followed by the excellent letter by* Mr Gissane (Dec 5) I considered that pharmaceutical manufacturers might be able to offer some useful advice, backed by experience in maintaining near-sterile conditions in an operating theatre The task of maintaining rooms with air of very low bacterial content has been carefully studied for a number of years by pharmaceutical manufacturers I would point out that any powders or liquids which cannot be sterilised in their final sealed containers must be packed under aseptic conditions followed by bacteriological control Contaminated batches are naturally discarded and packing is carried out in rooms larger than operating theatres with more people working in them So the problems are by no means insoluble

Mass-production packing of thermolabile drugs, such as penicillin and streptomycin, under strict aseptic conditions, presents difficulties similar in many ways to those of the operating theatre In each case a surprisingly large number of persons must enter and work in the "sterile area." There is much coming and going with many trolleys and trays of bottles, doors are opened and closed, and much delicate work is carried out under strict aseptic conditions with sterile instruments in gloved hands. Sterile clothing complete with mask head-dress, and boots *is donned on entering* the sterile area.

Pharmaceutical manufacturers rely on positive pressure in the sterile area, with rapid air changes. Thus all draughts are away from the sterile area. All surfaces (floors, walls and benches) are capable of being washed with antiseptic solutions. Dust-harbouring shelves and ledges are avoided, especially above bench level thus avoiding falling dust particles. Lights are built into ceilings. The positive pressure is produced by means of a fan blowing filtered air of very low bacterial content into the room at ceiling height This air is drawn from outside the building preferably above roof height, and passes through a filtration unit. It leaves by slit ventilators with hinged flaps which act as valves should the room pressure be reduced by say the opening of a door Thus, airborne dust cannot gain access to the area

The most important part of this scheme is to ensure that the air blown into the area is virtually bacteria free at all times. It has been recently shown by Sykes and Carter[1] that air of very low bacterial content can be produced by simply passing air under controlled conditions through filters of oiled "Fibreglass" or cotton fibre These filters are commercially available and under suitable conditions up to 99% efficiency is claimed.

The only sources of infection from outside the area are on the persons of the workers, who wear sterile clothing, and on the trays of bottles, which are fresh from the steriliser The main difference in this analogy would seem to be that the patients and the trolleys are so difficult to sterilise!

Ultraviolet light has been used by some manufacturers as an added precaution The sceptic might remark that it is only to impress visitors to the factory The use of ultraviolet radiation in the air inlet duct as an added precaution is however worthy of consideration

In its simplest form the plant for producing filtered air of low bacterial content consists of a fan drawing air through two suitable filters in series, followed by ultraviolet radiation in a short duct. The air could be adjusted to a suitable temperature by passing it through a standard electrical fan heater fitted with a thermostat

The problem of removing steam from the theatre can be dealt with by providing suitably placed ventilators fitted with the valves I have described. The positive pressure will ensure the removal of the steam

The use of extractor fans for this purpose as has been pointed out in your columns, is highly dangerous. The organisms drawn in from the hospital will be all the more dangerous because a high proportion of them will be resistant to penicillin and other antibiotics.[2]

I am sure that the large pharmaceutical manufacturers would be very willing to offer the wealth of their experience, through their medical information departments, to anyone requiring assistance in planning a suitable positive-pressure plant for an operating theatre

"YOUTHFUL CONTRIBUTORS"

SIR,—With humility and no little trepidation being still fairly young myself I write to question the need of older eminent writers to mention in the course of controversy in your columns, the age of their adversaries

Aspects of two subjects were recently raised about which it is surely generally accepted, there is still much to be known—namely the treatment of schizophrenia and the variability of intelligence I thought many of the points put by your correspondents were of help in getting a better understanding of the present knowledge of these subjects

It seemed therefore, to me, the more the pity that it was found *necessary* to criticise subjectively, on the grounds of their age those whose work stimulated useful discussion Surely the value of research and premise should be able to be judged objectively

Equally unfair would it be for the younger of us to draw attention to the age of your older contributors

St Clement's Hospital,
Ipswich.
M F BETHELL

DOSAGE OF MEPHENESIN

SIR,—In an earlier communication[3] I reported on the use of mephenesin in the treatment of various "rheumatic" complaints commonly encountered in general practice, and emphasised the importance of prescribing adequate dosage. The optimum daily dose, in my series of cases, was usually found to be 4–6 g given in divided doses every four hours, the minimum being two Tolserol tablets of 0·5 g four times daily Independently, Dr Nesbitt[4] has reported highly satisfactory results in 143 cases of similar disorders with associated spasm of skeletal muscle, and has suggested that tolserol should be given in doses of 1–3 g four or five times a day

Since my preliminary report was presented a number *of pharmaceutical firms have become interested in* mephenesin and I view with increasing concern the introduction of products containing the drug in quantities so minute that it can have no muscle relaxing effect Despite the wide differences between the doses which I have advocated and those provided by these products, the manufacturers concerned are quoting my report in their bibliographies.

My studies with this drug now include more than 400 cases, and I am convinced that it is very valuable for the treatment of "fibrositis" and allied disorders involving muscle spasm provided that proper dosage is employed. It should be stressed, however that any tendency to administer it in useless dosages will bring the drug into disrepute, thereby eventually causing sufferers to be denied a valuable adjunct in the treatment of "rheumatic" disorders

IDENTIFICATION OF PILLS

SIR,—The letter from Dr McQuitty in your issue of Dec 5 raises an important question Apart from exceptional circumstances, patients should know the medicines they are taking, because mystery and magic are unworthy of the physician who is a scientist and not a "medicine man" For this reason chemists should write the name of the medicine on the label of the container, or leave the original name on a container of a proprietary brand of medicine They should also return the prescriptions to the patients, who can thus follow more accurately the instructions of the physician—except, of course, in cases of dangerous drugs In Continental countries chemists are obliged to label the name of the medicines (even the formulæ of complex prescriptions) and to return the prescription This also helps to avoid accidents, which are far from rare

Changes of habit are imperative from this point of view Even Plato wrote in his *Laws* that the physician when dealing with free citizens must explain the medicines he prescribes, and only with barbaric slaves need he not take this trouble I am interested to note that Dr McQuitty got the chemist to put the name on the container by writing his instructions in Latin I have written similar instructions in English for years without any result—I shall try Latin next time

London W 1 A P Cawadias

METHYLCELLULOSE FOR OBESITY

SIR,—Like children who have been eating sweets before meals, obese overeaters who have been taking methylcellulose drinks beforehand cannot manage much either If they are instructed to be selective about what they leave—bread, potatoes, &c—they find their weight comes down after a while This, at any rate, was the experience of 10 people who tried the experiment

Of the ætiological factors in obesity, overeating from whatever cause is probably the commonest To cut down intake is easy enough in theory, but once overeating has become a habit or a "conditioned reflex," it is difficult, in practice, for the sufferer to eradicate it without help A number of remedies have been tried, with varying success, ranging from advice to dextro-amphetamine and minimal doses of sodium amylobarbitone, but the preparation I recommend is methylcellulose jelly, which has the advantage of being an indigestible bulk substance

A simple trial, lasting eight weeks, was made on 10 obese men and women whose overweight varied from 1½ to 4 stone They were otherwise fit and doing a normal day's work The results were good, including loss of weight of from 7 to 30 lb without any significant side-effects It was unusual to lose weight during the first week Some people experienced feelings of faintness or hunger occasionally, but a sweetened drink corrected this. Some were given vitamin capsules but those who did not have them are not showing signs of deficiency Furthermore, some of the group claim that on stopping methylcellulose jelly, they no longer have the desire to overeat—in effect a "reconditioning" to reasonable dietary habits appears to have taken place Only time will tell how long this effect will last, but once overeating recommences a return to the overweight state is inevitable As the trial was not strictly supervised and several people admitted forgetting their "dis-apéritif" on occasions the results are encouraging

Methylcellulose, a substance resembling "wood wool" swells up when suitably treated with water to form a 'jelly' It has been used as a bulk aperient in 22½ grain doses and his aspect is well described in Martindale, with a caution bout ossible formation of methyl alcohol in the intestine o reason, I prescribe only a week's supply at a s fear may be unfounded Mr K Gillanders

M.P S, kindly experimented to find a suitable form for di pensing This was found to be methylcellulose gr 7½ wit water to ½ fluid ounce (flavours as required, but it is left unflavoured) The method of preparation is important, however add to the required amount of methylcellu five times its weight of hot water, ensure that the mass thoroughly "wet," leave for about 30 minutes, make up volume with "chilled" water, and stir.

The patient adds a tablespoonful of the methylcellulose je to ½ pint of water (preferably) or other liquid In water it colourless and tasteless This is taken ½–1 hour befo meal times It is necessary to tell the patient that t mixture must be made up to ½ pint with liquid and th he must experiment as to the time of taking it He must n be discouraged if there is no loss of weight in the first wee The rationale of the treatment should be explained in simpl terms this is important, for an obese mentally defectiv patient (I Q 60), who was incapable of appreciating the rationale, gained 4½ lb during treatment.

The cost of ingredient for the jelly for 3 weeks' treatment is about 8*d.* wholesale, which compares favourabl with a proprietary preparation in tablet form (with vitamins) at 14*s* retail for the same period

Chertsey, Surrey J. N Badha

GRADING OF S.H M.O.s

SIR,—The whole profession is now aware of the wide spread 'dissatisfaction and feeling of frustration amon senior hospital medical officers in the Health Servic This letter is to present their case and to enlist sympath and active support in their efforts to secure justice

The arbitrary splitting of the ranks of specialists in two distinct grades was the mistake Gross injustice were done in the original grading, and indeed this wa recognised by the fact that subsequent reviews wer made These, however, have themselves been the subjec of criticism just as severe, and that there were stil prima facie instances of injustice was admitted in Dr Rowland Hill's annual report at the Cardiff meetin of the B M.A in July

Apparently no proper basis was ever laid down fo determination of grading Therefore, assessments in different areas have turned out to be contradicto This is well illustrated by the last and "final" revie when all the S H M O s who applied for upgrading in th North West Region were successful, yet, among tho who similarly applied in the North East Region, no one was made up to consultant rank. I believe o specialist who worked in both areas was upgraded the one and not in the other

There are three main groups of S.H M.O.s

(*a*) General practitioner specialists.
(*b*) Young specialists
(*c*) Older specialists

(*a*) A member of this group is generally satisfied with his lot He finds the interest of practising his specia a welcome change from general practice, and, as he not dependent on it financially, the question of salary not important Probably he is attached to a sma hospital and is on its staff committee, therefore h has reasonable control over the running of his department

(*b*) The young specialist who eagerly accepts the pos of S H M O as a stepping-stone to consultant rank finds on applying for a consultant post, that there are few such posts available and that he is faced with keen compe tion by registrars, perhaps from teaching ho who may well have excellent testimonials from e medical authorities As he fails to obtain one post another he tends to drift into the last group

(*c*) The position of the older S H M.O.s is indeed less under the present system What committe going to appoint a senior man at a higher salary f short term of service when a younger officer is availa with most of his professional life to come? Many of th S.H M O s have worked for years under the old system for no reward and now feel that they have had to accept a position of inferior professional standing Much despondency exists in the whole of this group and this must be reflected eventually in their work by a falling off in initiative and enthusiasm Their only hope of promotion lies in another ' national emergency '

Representation —Many S.H.M.O.s who are in complete clinical charge of their departments have no direct say as to how they should be run Whatever recommendations they have to make must be done through a third person

Remuneration —All S.H.M.O.s are agreed that the rate of pay compares very unfavourably with that of consultants, G.P clinical assistants, administrative medical officers and certain technicians.

A number of recognised consultant posts are filled by S.H.M.O.s, and their status and remuneration should be altered accordingly ' Consultant status and pay for consultant work.'

Lastly, and this point demonstrates the opinion of the Ministry of Health official secrecy surrounds the grade of S.H.M.O No list of names and addresses of officers holding this grade is allowed to be published.

Support is asked for either abolition of this grade and substitution of assistant physician, assistant surgeon &c, or for the following resolution

(1) That there should be an annual or biennial review of the grading of all S.H.M.O.s.

(2) That S.H.M.O.s should have full representation on committees controlling their work arrangements and other departmental interests.

(3) That the rate of remuneration should be revised

All can help by bringing this subject up for discussion publicly Such action would be welcome support for the negotiating committee of the B.M.A

EHLERS-DANLOS SYNDROME AND SUBCUTANEOUS MOVABLE SPHERULES

SIR,—The Ehlers-Danlos syndrome is a developmental mesenchymal dysplasia, often of strikingly familial incidence (mendelian dominant) The complete form is distinguished by the association of three main gene-abnormalities of development (1) over-elasticity of skin; (2) over-extensibility of joints and (3) friability of the skin and its blood vessels This last feature leads to the broad transverse papyraceous scars, which, when present across the knees constitute an almost pathognomonic sign of this syndrome. The over elasticity of skin, often particularly evident in front of the chest tends to be associated with a certain amount of cutis laxa, especially about the elbows where there are not rarely loose connective tissue lumps, or so-called pseudo-tumours (sometimes termed the fourth sign of the syndrome)

But the purpose of this letter is to draw attention to a fifth and no less interesting feature of the condition —namely the occasional presence of small pea-sized spherules which are freely movable in the subcutaneous tissue under the most elastic portions of the skin. Their presence may be missed on a superficial examination, and indeed may not be detected by the patient himself They seem to be due to an abnormal arborescent " growth of lobules of subcutaneous fat, some of the lobules becoming constricted and dropping off into lymph spaces, communicating freely with one another Probably in time, the separated lobules may become minute, oil containing, cyst-like spherules, with thickened or even calcareous walls.[1] The free movability of the spherules signifies to my mind a peculiar dysplasic arrangement of subcutaneous lymph spaces, analogous to, and perhaps a minor form of the very rare condition of subcutaneous lymph sacs or cushions " first described, I believe by Kuultzky and Melchior[2]

London, N W 1 F PARKES WEBER.

MELAMINE RESIN IN THE MAKING OF PLASTER CASTS

SIR,—In 1951 at the American Medical Congress held in Washington a film was shown by Dr M Cobey illustrating the incorporation of a resin called Melmac in plaster casts Melmac is the trade name for the substance melamine formaldehyde On further inquiry it was found that this material was made by Lederle Laboratories, but at that time a sample could not be obtained However on returning to Britain it was possible to get a similar substance marketed under the name of Beetle Resin ' by British Industrial Plastics Ltd This costs 5s 3d per lb Since then the resin has been incorporated in many plaster casts made in our hospital, and, apart from some initial difficulty in finding the correct temperature at which to use it, no serious difficulties have been encountered. When resin is used with plaster-of paris a lighter, stronger plaster can be made, and this is of considerable advantage especially when treating children suffering from bone and joint tuberculosis If radiographs are required through the plaster cast the thinner cast obtained by using the resin results in better detail

I have been informed by British Industrial Plastics Ltd that only one other hospital in Britain has been supplied with resin for this purpose, the request for it, in May 1953 was made after a demonstration to one of their orthopædic surgeons in Belfast.

Very little has been written on this subject In America, Spittler et al[3] reported two years experience with melamine formaldehyde in the making of plaster casts. They studied the properties of such casts in detail and came to the conclusion that it is possible to produce a stronger cast of reduced weight and bulk which is more resistant to moisture and soiling than the ordinary plaster cast The only other literature on the subject which could be found was an article in *Modern Packaging*[4] in which a method is described of using fibre cans containing a 'Polythene' bag into which the plaster bandage is dipped after adding water and catalyst to the resin in the bag Each fibre can is discarded to avoid clogging of plumbing with the plaster resin mixture, but in practice here we have had no trouble with clogged drains.

The method used is as follows:

300 g of resin is weighed out and to this is added 30 g of ammonium chloride which acts as a catalyst and speeds setting The mixed powders are then added slowly to one litre of warm water mixing them in by hand. The temperature of the water should be about 130 F to start with, and a good working temperature after dissolving the powder is about 120 F In all about 4 litres of water may be required adding from time to time to the original solution while the cast is being made This is done to prevent the plaster which may fall off home-made bandages forming with the resin a solid mass in the basin. It is necessary to work rather more rapidly than when using plaster bandages and water alone for if one is slow and the temperature of the soaking fluid is allowed to fall then a thick plaster cream may form. This can however usually be dissolved by adding more water, but this procedure may dilute the resin too much When the cast has been made some of the cream in the basin can be used to give a smooth glazed and partially waterproof exterior

[3] Spittler A W Brennan J J Payne J W *U.S. Forces med. J* 1953, 55, 373

[4] *Mod. Packag.* 1953 26, 90

Finally the bowl is washed out by adding a large volume of water and the solution is poured down a sluice

The setting of plaster is generally regarded as an alternating process of dissolution of soluble anhydrite or calcium sulphate hemihydrate, or both, and crystallisation of the dihydrate gypsum as a mass of interlocking crystals Colloids such as glue or gelatin increase the viscosity of the solution, retarding circulation or molecular mobility and interfering with crystal growth, thereby retarding setting Urea formaldehyde resin solutions tend to retard setting in a similar way On the other hand, salts which tend to increase the solubility of gypsum in water tend in small amounts to accelerate the rate of setting Ammonium chloride and hydrochloric acid have such an effect

Formaldehyde combines quantitatively with the ammonia of ammonium salts in general and liberates the acid Urea formaldehyde resins behave similarly, but more slowly, and the free acid then promotes further condensation of the resin, resulting in setting and hardening Setting of the plaster thus takes place in a medium of progressively increasing viscosity Possibly the net result with a urea resin plaster mixture is a finer grained cast comprising smaller crystals superficially glued together with urea resin and less dependent upon mechanical interlocking for ultimate strength

Spittler et al mention that 3 out of 7 children in their series developed dermatitis This has not occurred in any of our patients, but it is advisable for the operator to use gloves, for if the resin and ammonium chloride are mixed with the bare hand, the skin begins to tingle and redden

In applying the resin soaked plaster bandages, it is advisable to put them on, especially in the case of body casts, a little more tightly than usual, for on drying the plaster tends to spring out from the skin a little It is found that the casts set more rapidly than is usual and quickly become very hard. Removal of the casts is said to be more difficult because of their hardness, but we have found no particular difficulty in taking them off, using either a simple plaster knife, plaster shears, or an electric cutter In this hospital plaster casts are always finished off by coating them with celluloid dissolved in acetone to which calcium chloride has been added, and this procedure also strengthens the surface of the cast while making it waterproof and very easy to clean It has not, however interfered with the removal of the cast even when it ha been made with resin

NUMBER OF BANDAGES AND WEIGHT OF CAST, WITH AND WITHOUT RESIN

Age of patient (yr)	Part plastered	No of bandages				Weight of cast (lb)	Remarks
		8 in.	6 in	4 in.	2 in		
12	Leg	1	1	—	2	—	300 g resin
10	Double hip spica with extension to lt. ankle	2	4	—	3	$8\frac{1}{4}$	300 g resin
		5	5	—	1	—	200 g resin
5	Jacket with shoulder straps	—	3	—	1	—	300 g resin
		12	—	8	—	—	Without resin Patient now in this cast
3	Jacket and rt arm down to wrist	—	4	—	2	$2\frac{1}{2}$	300 g resin
4	Jacket only	—	5	1	—	—	150 g resin
17	Double hip spica with extension to lt ankle	6	6	—	—	$9\frac{1}{2}$	300 g resin Without resin, a similar plaster weighed 21 lb
12	Double hip spica with extension to lt. ankle	8	13	—	2	11	300 g resin
		11	8	13	4	14	No resin (Plaster cracked in upper part)

The accompanying table gives a few examples o comparative numbers of bandages required, and th weights of some casts made with and without resin The figures clearly illustrate the considerable saving i plaster bandages and the reduction in weight which ca be achieved by this method It is evident that 300 g resin is about the correct amount to use, for with 150–20 g more bandages are required If the solution is mad too concentrated and if the temperature is too high, the resin settles out as a sticky rubbery mass on the basin an on the operator's fingers as he mixes it In order t simplify matters, a firm making plaster bandages ha been asked to try and incorporate the resin into the plaster bandage, but so far they have been unable to d this

Medical superintendent.

FAIR PLAY FOR THE STAMMERER

SIR,—The rapid increase in the number of speech therapists has brought with it a correspondingly widened scope of activity, but there is a danger that the cases which should have priority will be pushed aside in favour of those that are easier to treat

As a former stammerer, like many of the pioneers of speech therapy, I decided to give up general teaching to devote all my time to the correction of stammering and cleft palate speech, but as soon as I accepted a post on the staff of a teaching hospital I found my clinic crowded out with backward speakers, lispers, &c, most of whom would correct themselves if left alone or who could be dealt with by a school-teacher or parent By seeing such cases once and once only I was able to concentrate on the stammerers

The stammerers should enjoy priority if only because the great majority are above the average mentally—indeed a considerable proportion are of scholar or exhibitioner standard—nor are they less able to take a lead in games They are, in fact, potentially valuable citizens handicapped only by a speech habit which has developed in the majority of cases by direct or indirect imitation After their correction by speech re education, stammerers are able to take their rightful positions in the world, but many are being held back in favour of children with ordinary baby inaccuracies and, even worse, of mentally deficient children

Within the last few months a very bright little boy of 10 was taken to one of the teaching hospitals, after waiting for very nearly two hours his mother was told by a student that there was a waiting-list of a year The speech therapist in charge had seen neither the mother nor the boy, nor had there been any examination or interview The mother wisely decided to seek private treatment and the stammer was corrected. Had that step not been taken the result might have been similar to another experience Several years ago a bright boy won a scholarship to one of the London grammar schools but when interviewed by the headmaster the boy was refused because he stammered he turned to mechanical work which he disliked, so after seven years he gave it up He now drives a taxi

The correction of typical infant speech disorders is straightforward and makes no great demands on the speech therapist, and it may be interesting to increase the vocabularies of the mentally deficient, but the former will correct themselves in most cases, while the mentally deficient can never become such useful citizens The correction of the stammerer's speech calls for endless patience, while the psychological repercussions that often develop make great demands on the personality of the teacher, but it is more than worth while because it enables the stammerer to assume his rightful position and the mmunity to benefit from his abilities Speech therapy a vocation and if treated so will secure for the mmerer the priority he deserves

H ST JOHN RUMSEY
Consulting speech therapist
to Guy's Hospital.

London, N W.1

THE INSULIN MYTH

Sir,—Dr Hunter's contribution (Nov 28) to the ntroversy over the respective merits of E C T and ep insulin in the treatment of schizophrenia is in ct an attack upon *all* physical methods of treatment. hile not being representative of the views generally ld in the department of psychological medicine at uy's Hospital on this subject—for which all honour the individuality of the author—it contains a certain mount of special pleading The clinical improvement isplayed by patients who respond to deep insulin erapy is not a mere induced anosognosia; nor is ch treatment simply an irrational therapy

Apart from the work of Quastel Himwich and ellhorn, mentioned by Professor Mayer Gross in his tter in the same issue there is a recent paper by Lovett oust[1] which describes the effects of insulin-coma erapy upon blood-oxygen saturation, emphasising he correlation between a significant increase in such vel following treatment, and clinical improvement n the patients so treated—The author points out that is investigation confirms essentially similar findings y other workers of the effects of insulin therapy upon rterial pressure and cerebral metabolism

Deep insulin treatment remains in fact a standard rocedure for selected cases of schizophrenia treated n the York Clinic of this hospital where it seems to ost of us to continue to be justified by results

Guy's Hospital,
London, S E.1

DAVID STAFFORD CLARK

CORTISONE AND RHEUMATOID ARTHRITIS

Sir,—It was a pleasure to read the article by Dr West nd Dr Newns in your issue of Nov 28 The statement hat cortisone acetate (50–75 mg daily) administered to 27 patients with rheumatoid arthritis over an average period of nineteen months was not to be recommended nd does not favourably influence the course of rheumatoid disease, is of considerable importance especially coming from rheumatologists. The conclusions were reached in a controlled series with a very fair assessment, based on accepted criteria

As they point out, the profound effect of cortisone in a daily dose of 100 mg or more on the symptoms and signs of the disease in the early weeks of treatment is an acknowledged fact but doses of 75 mg or more can rarely be maintained for many months without serious complications

Since its introduction into this country from the U S.A , the supplies of cortisone have depended on dollar exchange or generous gifts, and the restricted amounts, more precious than gold have been delegated to various hospitals and centres for treatment of rheumatic diseases where fundamental or essential research was supposed to be carried out, although much of this had already been adequately completed on a vastly larger scale in America.

Although it is accepted that cortisone in addition may be of considerable benefit in some of the collagen diseases certain skin diseases eye conditions, and acute rheumatic fever the more rationally and logically treated diseases such as Sheehan's syndrome, Addison's disease and adrenocortical hyperplasia with excessive androgen production, have had to manage with second best or merely glean the crumbs which dropped from the rich man's table Other indications are already apparent from the literature such as cortisone maintenance following hypophysectomy or bilateral adrenalectomy for advanced carcinoma of breast or prostate or for gross hypertension

It is very laudable that we should gain experience with this new hormone and confirm or confute the American experimental work but it was estimated last year[1] that home production of cortisone would exceed the then consumption by July of this year I understand that much of the material hitherto in use in this country was made by the French laboratories of Roussel, whether or not the dollar exchange operates here, I do not know Further, I am informed that in the not too distant future, more manufacturing chemists will be making cortisone in Britain

May I make a plea that cortisone should be more readily available to the medical profession and not only to the privileged few I feel that there are already adequate safeguards in the N H S both in hospital and general practice to deal with unjustified use of expensive drugs, and, as regards the dangers of overdosage it is reasonable to assume that if a doctor is sufficiently intelligent to prescribe the correct dose of morphia insulin nitrogen mustard or a host of other more potentially harmful substances then he is fit to treat his patient with cortisone provided there are acknowledged indications.

Most new therapeutic discoveries suffer at first from over-enthusiastic use and wild claims, but in the end a reasonable and balanced judgment prevails, and Dr West and Dr Newns must be congratulated on helping to swing the pendulum

Bristol.

GEORGE L. FOSS

FLORENCE NIGHTINGALE HOUSE

Sir—Advanced work for nurses was an important aspect of Florence Nightingale's nursing policy She wanted nurses of all nations to be what she called missionaries of health ' by training others and raising the standard of health wherever they went

Next year will see the centenary of Florence Nightingale's mission to the Crimea The National Florence Nightingale Memorial Committee in the United Kingdom is seeking funds to establish permanently a fitting memorial to her noble work and inspiration It is proposed

(1) To endow a residence for 44 nurses of all nations while undergoing advanced courses in London

(2) To further the advance of nursing education by the award of scholarships.

Throughout the world, similar national committees are raising funds for the award of scholarships to nurses They are all part of the Florence Nightingale International Foundation which is concerned with nursing education internationally

The successful candidates come to Britain and reside at Florence Nightingale House 173–175 Cromwell Road S W.5 during their postgraduate training adding an additional responsibility to the committee in this country but this is the land of Miss Nightingale's birth and we must not fail in our duty to her memory

We therefore appeal to everyone who appreciates her magnificent work for the nursing profession and to everyone who has experienced the kindness of a nurse, and to everyone who wishes to express in tangible form their gratitude Please either send a donation, or write for a copy of an informative illustrated booklet to the Florence Nightingale Memorial Committee of Great Britain and Northern Ireland, 12, Whitehall, London, S W 1

LUKE
Chairman.

Medicine and the Law

Successful Appeal against Verdict of Negligence

EARLIER this year a patient obtained the substantial award of £4000 as damages in an action alleging the professional negligence of an anæsthetist[1] Admitted to Charing Cross Hospital for an operation for removal of the bladder, he received blood-transfusion, his left arm being extended for this purpose at an angle of 80° He complained that he subsequently suffered a loss of power in the arm amounting to paralysis The verdict has now been set aside by the Court of Appeal[2]

The evidence of medical practice was clearly the crux of the case, and the argument and judgments on appeal have made it clear that the trial judge was impressed by the fact that, when the operation occurred in July, 1950, the defendant doctor was unaware of an article published in *The Lancet* in the previous January[3] The judge evidently took the view that a failure to keep abreast of the professional journals was negligence The Court of Appeal is satisfied that, if the negligence amounted to no more than this, it is not enough. There was evidence at the trial that abduction up to 90° would do no harm Statistics showed, said Lord Justice Somervell, that in only approximately one-third of 1% of such operations did brachial palsy follow, and generally it was not permanent The learned Lord Justice declared that there was no evidence of negligence Concurring with this opinion, Lord Justice Denning commented that actions against hospitals were now becoming common It must be understood, he said, that not every mishap which might occur in the course of hospital treatment would place upon the hospital the burden of an explanation Mishaps often occurred without negligence on anyone's part The plaintiff had entered the hospital for an operation to save his life It had been proved that the hospital exercised all reasonable care As for the *Lancet* article, "it would be putting much oo high a burden on medical men to say that they must ead every article in the medical press."

Alleged Negligent Certification

In a recent action[4] at Hampshire assizes the plaintiff, a State registered nurse and the proprietor of a Bournemouth nursing home, claimed damages for having been, as she alleged, wrongfully certified as a mental patient and put into a mental hospital Her counsel, opening her case, said that in 1949, when she was 43, she had suffered from a septic condition of the finger nails, perhaps due to overwork, undernourishment, and possibly mental strain In November she entered the defendant doctor's nursing-home for rest and treatment By Nov 23 he reached the conclusion that she required to be certified, she was sent to a mental hospital

Giving judgment for the defendant, Mr Justice Parker said that the plaintiff's description of conditions in the mental hospital had been exaggerated and false, though not deliberately so She had felt herself persecuted by members of the medical profession and in particular by the defendant. His Lordship was satisfied that she really was mentally ill when she went to the defendant's nursing home The defendant had consulted a specialist, and this precaution completely exonerated him from any charge of having failed to exercise reasonable care in taking the step of certifying the patient The court, however, allowed the defence only 50% of the costs because of certain difficulties placed in the plaintiff's way, the absence of records, and the consequent

protraction of the proceedings The judge said h that the medical defence society concerned mig it was a case in which they need not ask even 50% allowed

Obituary

WILFRED SHAW

M A., M D Camb, F R.C.S., F R.C O G

Mr Wilfred Shaw, surgeon in charge of the gyn logical and obstetrical department at St Bartholome Hospital, died in London on Dec. 9 a few days befo his 56th birthday By his death his specialty has l an original mind and a fine surgeon, and his hospi one of her most distinguished sons and loyabl characters

He was born in Birmingham, the son of the late Isaac Shaw, J P, and educated at King Edward's Scho Birmingham, and St. John's College, Cambridge, whe he was open scholar, foundation scholar and exhibitio and Wright's prizeman, and took a first-class in par in the natural sciences tripos. He consolidated t successful start by winning at Barts the Matth Duncan prize and gold medal, the Lawrence rese scholarship and gold medal, and the Cattlin resea scholarship Thus early he showed the bent inquiry to which we owe his classical papers on ov tumours and the anatomy of prolapse.

He qualified in 1921, took the F R.C.S. in 1923, an proceeded to the M.D in 1928 During these years served a useful apprenticeship at Barts as midwif intern and, later, as house-surgeon to Sir Charles Gordon Watson and as chief assistant for two years to the dep ment of obstetrics and gynæcology But not con with these postgraduate qualifications, he sought fur experience in Vienna. The Viennese school was influence him for the rest of his life, for there he learn to master the technique of vaginal surgery

In 1926, the post was created at Barts of residen assistant physician accoucheur, which was at that unique in London. This post carried with it consider teaching responsibilities and the handling of a l number of obstetric and gynæcological emergenc Wilfred Shaw was the inevitable first choice for appointment, which he held continuously for five yea and from which he acquired a solid clinical experien second to none in the country In 1931 his postgradua studies were rewarded with the Jacksonian prize of th Royal College of Surgeons, and in 1933 an Arno demonstratorship followed—both rare distinctions for a gynæcologist. In 1932 he was elected F.R.C.O G

He was elected to the honorary staff of Barts in 1931 as assistant physician accoucheur His new appointment gave him full scope to develop his gifts as clinician and teacher. As a teacher he was superb, and his lectures and grinds were the ultimate basis of that world-famous book, Shaw's *Textbook of Gynæcology*. He always ma tained that this book was inspired by, and intended fo his own Barts students In a few pages it certain contained enough meat to pass all the exams, not exclud ing the M.R C O G As an examiner in the Conjoint London, and Cambridge finals, he was scrupulously and generous to a fault, as many an unhappy candida will bear witness. He disliked examining because kind heart and sensitive nature rebelled against inflictin a penalty on a student whose ability he instinctivel divined, however poor his showing under the fire his co-examiner At examiners' meetings he was a fearl champion of the doubtful candidate, and this somet led him into conflict with his colleagues.

J H. writes: "Wilfred Shaw was more than gynæcologist, he was an anatomist, a scientific sopher, and probably the greatest gynæcological p logist in Britain. The Williamson Laboratory at was dear to his heart, and here, with his old and technician Bert Cambridge, he cut, stained and examined many thousands of sections, and his colle of slides and specimens is testimony to their ti industry He had a great reputation as a patholo and his colleagues and friends from all would bring him difficult slides for his interpretation and judgment. He always had a microscope in outpatients and in his consulting-rooms, and after a cursory glance, he would resolve the problem with a curt diagnosis. There was no court of appeal and, if there was, the old man was almost invariably right. Incidentally, he christened himself the ‘old man’ with that puckish self depreciation which at first perplexed but ultimately endeared him to us all

‘His housemen and students learned to await with lively anticipation his invariably punctual arrival in the Rolls—never driven over forty in its life—the gay salutation, the teasing repartee the teaching round packed with wit and wisdom.

“His teaching sessions in outpatients were unforgettable. Though his students came to learn gynæcology, they achieved more than this simple object. Elizabethan poetry and drama, higher mathematics, nuclear physics, international politics the history of Barts, all came within the syllabus. He knew the name of every Barts student, his history, his wife’s name and the number and names of their children, whom he had probably delivered himself His amazing memory was once tested on View Day, when Barts is at home to all her old students. A quiet, unassuming middle-aged general practitioner approached Wilfred to pay his respects with the remark You won't remember me Sir I haven’t seen you for twenty years. A puzzled frown gave place to sudden enlightenment as he saluted his old student by name and inquired after his wife and partner Shaw was a voracious reader and reviewer of the British and foreign literature, and his memory seemed to enable him to place his finger on any article about any subject and to quote the author almost verbatim.

‘Wilfred loved people To him his patients were all real friends and he knew all about them and their families. His old outpatients adored him and his private patients invariably became his friends. No service, great or small was too much trouble to him and he lavished his care upon them for small or no remuneration He had an enormous practice amongst doctors wives, and his great house in Harley Street was choked with the tokens of their gratitude Here he would receive a visiting Indian surgeon an old Barts nurse, a student in need of advice a young aspiring consultant, or a gynæcologist with a difficult slide; each with a problem for this good Samaritan and beloved physician, to the solution of which he bent his rich wisdom and kindness.

“As a surgeon, he was quick, dexterous and neat, essentially an anatomical operator, he invariably found the correct plane of cleavage His repertoire of operations was limitless but he was at his best with a difficult vaginal procedure say a tricky vesicovaginal fistula. All prolapse surgery, and, in particular, the problem of stress incontinence and hernia of the pouch of Douglas, is the richer and better for the anatomical researches and the carefully planned techniques of Wilfred Shaw He loved the skill and artistry of operative technique and he chose to spend his last two years writing the textbook of gynæcological surgery which he finished a few weeks ago When this book is published, it will stand as a monument to his courage as a man and his greatness as a surgeon.

‘Si fractus illabatur orbis
Impavidum ferient ruinae.

Mr Shaw leaves a widow, three sons, and a daughter

Notes and News

MEDICAL RESEARCH COUNCIL OF IRELAND

THE many investigations sponsored by the Medical Research Council of Ireland during 1952 are described in some detail in the annual report that has lately been published. The work on the chemotherapy of tuberculosis has continued with renewed vigour, thanks both to the enthusiasm of Mr Vincent Barry D.Sc., and his colleagues and to the generosity of University College Dublin, in providing the first instalment of a grant from the Lasdon Foundation The grant made it possible to carry out extensions to the council’s laboratories. An interesting observation made during the year’s experiments was that isoniazid resistant strains of tubercle bacilli show a greatly reduced virulence for guineapigs.[1] A number of novel derivatives of isoniazid have been synthesised in the laboratories; some of them show activity of the same order as isoniazid but further inquiries are needed to decide whether any of them are significantly better than isoniazid

Among other investigations, Dr T Counihan has made phonocardiographic studies of presystolic triple rhythm and the opening snap of the mitral valve Evidence from œsophageal phonocardiograms suggests that there are two auricular sounds, the first probably produced in the auricle itself and the second in the ventricle as the result of auricular action The latter sound is normally inaudible, but it becomes audible in heart-block, constituting then a form of presystolic triple rhythm. Dr Counihan has been working on this subject at the Postgraduate Medical School of London.

Prof W J E. Jessop has conducted a survey by means of a simple screening test for disturbances of carbohydrate metabolism of a diabetic type among elderly patients attending a urological clinic. The results showed that about 25% of patients over the age of 60 had a metabolic disturbance of diabetic type Many of them did not require treatment but in some cases insulin was necessary As yet it is not possible to say how far treatment of the metabolic disorder affected the course of the disease for which the patient came to hospital in the first place

During the year the council spent £8678 on general research and £8942 on work on the chemotherapy of tuberculosis. Other expenditure included £600 on cortisone research and £17 346 from the special grant for the National Tuberculosis Survey

TEETHING-POWDERS

LAST week (p 1247) we discussed the use of teething powders, and we are glad to record that Messrs. John Steedman & Co makers of a popular powder have announced that they had decided some months ago to remove calomel from their powders. Distribution of the new mercury free powders began this month. This wise decision was made public on Dec. 9 at an inquest[2] on a 10 month old girl who had died of pink disease.

DANGEROUS DRUGS ACT

AN order[3] which came into operation on Dec 14 applies part III of the Dangerous Drugs Act, 1951 to the salts of N Allylnormorphine and any preparation, admixture extract, or other substance containing any proportion of N Allylnormorphine which will as from Dec. 14 come within the provisions of the Dangerous Drugs Act and the regulations made thereunder

SOCIAL SECURITY BENEFITS

RECIPROCAL arrangements on social security benefits between Great Britain and Australia will come into force on Jan 7[4] The arrangements will enable people who go from this country to Australia to receive benefits under the Australian scheme to supplement any retirement pension or widows benefits which they may be receiving from the Ministry of Pensions and National Insurance People who come from Australia to this country will be treated as if they had been insured under the National Insurance schemes while they were in Australia so as to help them to qualify for National Insurance benefits here

3 The Dangerous Drugs Act, 1951 (Application) (no. 3), Order 1953 S.I 1953 no 1680 H.M. Stationery Office 3d
4 The National Insurance (Reciprocal Agreement with Australia) Order 1953 S.I. 1953 no. 1772. H.M. Stationery Office. 6d.

A separate agreement with Australia on family allowances will come into effect on the same day under regulations which are being made by the Minister of Pensions and National Insurance This will ensure that families going from one country to the other will be able to qualify for family allowances in the new country as soon as they arrive there

MEDICAL ARCHIVES

A DOCTOR'S diary giving details of George III's illness, diaries of a surgeon who sailed in emigrant ships to Australia (1840–50), and a licence to practise medicine (1777) found among a collection of papers in Dorset are among the items of medical interest in the latest *Bulletin* of the National Register of Archives. The official correspondence of Sir Stafford Northcote, 1850–55, now calendared by the register, includes letters from Florence Nightingale The most important manuscripts in the collection of the Royal College of Physicians of London are also listed in the *Bulletin*, they include deeds from different parts of the country, ranging from 1444 to the present century

The National Register of Archives was set up in 1945, under the Historical Manuscripts Commission, and its purpose is to collate, and as far as possible to collect notes of the contents of, ancient and modern documents in private hands, or belonging to local authorities and institutions such as hospitals, and societies. The address of the register is c/o the Public Record Office, Chancery Lane, London, W C 2 The National Register of Archives for Scotland is at Register House, Edinburgh

FILMS ABOUT MOSQUITOES

THE Wellcome film unit has produced two new 16-mm films, *The Dissection of a Mosquito for Malaria Parasites* and *Pinning Mosquitoes* Both are in colour with sound.

The first is a demonstration by Mr P. G Shute, of the Medical Research Council's Malaria Reference Laboratory The phases of the life cycle of the malaria parasite within the mosquito are briefly described and the appearance of both oöcysts and sporozoites is shown. The film then demonstrates how the salivary glands of the insect are pressed out and prepared for examination so that the sporozoites can be identified. The removal of the stomach and the detection of oöcysts are then demonstrated The running-time is 10 minutes.

The second film shows how mosquitoes should be pinned, how to stage and label the pinned insects for permanent display, and how to pack them for dispatch through the post It was produced in collaboration with the department of entomology at the London School of Hygiene and Tropical Medicine The running-time is 5½ minutes

The films may be borrowed on application to the public relations officer, Burroughs Wellcome & Co, 183–193, Euston Road London, N W 1

JEWELLERY AS THERAPEUTIC OCCUPATION

ABOUT five years ago the Goldsmiths' Company[1] pointed out that simple jewellery and metal work would be a satisfactory form of occupational therapy for many patients obliged to spend a long time in hospital Having gained the support of the appropriate organisations, it gave a grant to Mr Claude Geoffroy Dechaume, a designer craftsman, enabling him to demonstrate to occupational therapists the possibilities and limitations of such work, and under the company's auspices he produced a book on *Simple Craft Jewellery*,[2] soon to appear in a second edition. Based on this book a film of the same name has now been made by Mr F H. Dowden of the Ministry of Education, and it had its first showing at Goldsmiths Hall on Dec 7 to representatives of the Association of Occupational Therapists, the British Red Cross Society, the Central Council for the Care of Cripples, and other bodies concerned with the teaching of the disabled Intended for use in hospital occupational therapy departments, training schools, craft workshops, and the like, the film shows how patients doing this work. A small but fascinating exhibition of various kinds of jewellery, mostly made with inexpensive materials, was on view at the hall during the subsequent few days, for the benefit chiefly of students of occupational therapy It can hardly have failed to make them emulous

The award of the first gold medal under the newly Sydney Body Trust has been made to Dr William Evans work in cardiology

The British Standards Institution has issued a standa (B.S 2044 1953) covering laboratory tests for resistivity conductive and anti-static rubbers. Copies (price 2s 6d.) may b obtained from the sales branch of the institution London, W 1

EDUCATION FOR ELIZABETHANS *

Lord RADCLIFFE
P C, G B.E., M A Oxfd
A LORD OF APPEAL IN ORDINARY

AT the recent congress on medical education much as said about the need for the future doctor to have general education and a general background of culture That is not a problem peculiar to those who are being ducated in the study of medicine You will equally nd today that those who are interested in, let us say he technical training of engineers advocate the advan ages of supporting their specialised knowledge with wider general education You will find that leaders f industry are begging that they should be supplied ith a stream of persons not merely qualified to be experts n their particular branch of study but also with a wider eneral background It is one of the problems of our ime. But what to do about it and how to solve it?

You see the times have changed since the days when eneral education represented a recognised curriculum t is quite right for the young person to wish to be a pecialist. If his wits are alive he realises as he advances n study the fascinations and the potentialities of his articular subject, and he dives rightly head foremost nto it with all the enthusiasm that he can command. It is a good thing for to become a master of a craft is something which gives a man self-confidence and a footing in life which he will not otherwise acquire. It is a good thing

Remember, too, that the days when there could be a man of universal knowledge have passed. The sheer accumulation of vast stores of learning in each field, the great range of subjects which are now open to be included among the various branches of learning have put us a century perhaps two centuries, beyond the time when any one man could say I represent universal knowledge and I see it all in all its branches under my eye, and I take a picture of the whole.'

Somebody once said that Sir Christopher Wren was one of the last of those universal men Others have claimed it for Goethe But if it were possible in those days, it is not possible now and with this enormous accumulation of specialised learning it has come about that the old general curriculum upon which education and culture were founded has broken up The mould is broken and there is not that set course of the humanities in which we were taught to believe in the past Indeed we are now called upon to remember that the old general classical education in the humanities was in its *day nothing but a vocational training to equip* candidates for the medieval Civil Service

But, again what is to be done? We all agree that we should be better men and fuller men if we had behind us a wider range of education. I am sure Twenty Questions on the B B C. however assiduously attended will not provide the answer nor even the illuminations of the Brains Trust nor even however well chosen a course of lectures on potted culture But if I may, I will make two suggestions to you which may be of some assistance.

* * *

One is to keep your curiosity alive. I should like to put in a word for the value of curiosity as one of the great influences of civilisation For it will come to pass, as you become a master of your own craft that the certainties recede, enthusiasms to some extent fade but if you can keep your curiosity and your inquiring mind alive, that you will find, will sustain you until the end. If I may say so, back your fancy; let your curiosity take you into the paths which fascinate you or appeal to you and do not let it be dominated by what other people around you or in the past have said are the great or the important or the beautiful things. If you remain curious and do not take things for granted you will find however specialised your path, that life is continually opening out before you and showing you new fields in which your mind can dwell

It is taking things for granted and not asking why and how they are there—the very denial of the scientific spirit—that makes people limited in their interests. We all look every day at the skyline of London and never ask ourselves by what miracle of energy and acquired skill that great monument of St Paul's still dominates the skyline of the City one of the great architectural monuments of the world. When we go to the country we look at the country scene and we never even notice, because it is so much there, that wherever we look there is a church spire which is part of the landscape We do not set ourselves wondering by what miracle of a continuity of civilisation we have come to take it for granted that the church spire is an inevitable part of every country scene

* * *

In some countries, without a long history on record, it might not mean much to say 'Keep your curiosity alive,' because it might not lead very far, but in this country in which we are so intimately tied up, whichever way we move, with our own past history and the great civilisation to which we belong and have belonged it almost requires going about in blinkers not to be reminded of it.

Last summer at Stratford, I was struck by the evidence of the extreme popularity of Shakespeare's plays in this country today: crowds of people thronged the theatre at every performance, standing outside in queues for the chance of admission from a returned ticket for one of the five plays presented at the Festival I see that the Old Vic are presenting two more—perhaps one of the great Hamlets of our time—and are setting out on a cycle of five years in which they will produce in due order every single play written by Shakespeare a dramatist 350 years back from our times and of whose life and personality it would be true to say we know almost nothing

I was wondering whether this great feeling of response to Shakespeare's work today represents something that is common between the situation of our time and the situation of those times in which he wrote.

What piece of work is a man! he makes *Hamlet* say How noble in reason! how infinite in faculties! in action how like an angel! in apprehension how like a god! the beauty of the world! the paragon of animals!' So may we say as, with all the resources of modern civilisation at our command we realise the unlimited possibilities that stretch before the human creature—if only he will do himself justice.

Yet Shakespeare makes Hamlet place this creature with all his potentialities against a dark background:

> this brave o'erhanging firmament, this majestical roof fretted with golden fire why it appeareth nothing to me but a foul and pestilent congregation of vapours.'

So it may seem to us when we see the inmost secrets of Nature and the great resources that lie still untapped in the firmament conscripted to form the major instruments of man's destruction That seems to be the dilemma of our time, and I think it was felt the dilemma of the times of the first Elizabethans

Do we at all share their solution when we face our problems? They were a race strange to us for all our love of their literature. They were greedy and avaricious, they were ambitious, they had a mania for power, but they were men who had a taste for magnificence, they had a taste for greatness, and they had a feeling for what they understood by Honour By our standard they were curiously indifferent to success What mattered to them was the glory of the attempt and the achievement and not the ultimate reward or recognition

---

* Part of the inaugural address given at Westminster Medical School on Oct 12, 1953 The full text appears in the Dec. 18 issue of the school magazine *Broadway*

You see it reflected so clearly in Shakespeare's plays Ie wrote comedies, of course—lovely fairylight things oathed in an unreal sunshine, in which nobody was supposed to take seriously what happened or the result "It is just the prettiest thing in the world," Lord Melbourne told Queen Victoria about *As You Like It.* But what Shakespeare never wrote, as far as I can remember, was a play in which the good man, while faced with adversity and tried by troubles, emerges triumphant and successful at the end What he wrote were these tragedies in which the great man—Brutus, Antony, Hamlet, Othello, Lear, Coriolanus—goes down to ruin, and goes down to ruin with those he loves involved in his destruction, not because of any challenge that he in his pride had made to fate, not because of any vice which is being punished or avenged by the moral law in his person, but because he is in the hand of a fate that is hostile to him and by a darkness that he cannot overcome

That is not a cynical or a desperate presentation of man's dilemma, because you do not feel while you watch these plays, nor do you come away at the close feeling, that darkness in the end is triumphant But they do throw you back to the feeling that it is not success or failure itself which is the thing for which man is set here in his environment, but that what matters is his total gesture, and that there are moments of great light in the life of every person—moments to which all of us, without reason and without philosophy, respond—which justify the human experiment At the end, I think, you feel vividly that although the solution may be hid in mystery, at least it is plain that the answer is not now and the solution is not here That is something of what the predicament meant to the Elizabethans

* * *

You may follow them further, if you care, in the works f the man whose tercentenary we were celebrating last ear—in Hakluyt's account of the Elizabethan sailors You will find a proud record of people of endurance and of daring who in little ships, of 20, 30, 50, or 100 tons, went out into the unknown Atlantic searching for the North-West Passage or out to the North of Scandinavia looking for the North-East passage—men who faced odds of all kinds without self pity and without complaint, against powerful enemies and more powerful fleets, against ice and fog and storm, against pestilence and disease, and men who at the same time had—or many of them had—a simple faith that they were in the hands of Providence in the risks that they were taking As one of them wrote in Hakluyt,

'God, who doth give limits to man's times, and ordaineth the manner and circumstance of dying"

But feeling themselves in the hands of Providence, they felt no less the need that they should show themselves skilful captains and skilful sailors, and when the end came, as it often did, in disaster and not in success, and one more ship and its crew went down in battle or the storm, they closed the record with dignity and without amentation This is what Raleigh wrote of his friend ir Richard Grenville after the ship *Revenge* had sunk ollowing the fight with the Spanish fleet

"What became of his body whether it were buried in the se on the land, we know not, the comfort that rem his friends is, that he hath ended his life ho respect of the reputation won to his nation and country, and of the same to his posterity, and being dead, he hath not outlived his own honour

Those are fine words.

I do not think it out of place to recall the na of those men, something of what they did and someth of what they believed, in this beginning of your term Coronation year, when we are told that we are to be second Elizabethans and there is a second Queen Elizabe on the throne It can not be wrong to recall that man of those men were citizens of this very ancient city which you do your work and that it was upon the Tham almost under these windows, that "they hoist up and committed themselves to the sea," just as t and the future years will bear you to your fu which will be, as I so much hope, happy and fru and not without adventure

INVESTIGATION OF OBLITERATIVE ARTERIAL DISEASE OF THE LOWER LIMB

DAVID MESSENT
M.B Lond., F.R C.S
ASSISTANT LECTURER IN SURGERY

R E STEINER
M.B N U.I., D.M.R., F.F.R.
LECTURER IN RADIOLOGY

JOHN F GOOD
M.D Lond., M.R.C
LECTURER IN MEDICINE

POSTGRADUATE MEDICAL SCHOOL OF LONDON

THERE is no general agreement about the value o various tests used to determine the integrity of peripheral circulation, and special investigations often considered to be of limited practical significance The widening of the field of direct surgical appro to diseased arteries has emphasised the importance an accurate knowledge of disordered function a anatomy We therefore felt the need to comp various methods of investigation and to assess th value, with particular reference to accurate diagno and treatment, and to ascertain which of these metho may usefully be retained in everyday practice O conclusions are based on a study of more than 100 patients with arterial disease of the lower limbs, althoug it was impossible to make all the investigations on each patient

Aims of Investigation

Before any investigations can be discussed, their aim must be clearly defined, and in the case of peripheral vascular disease these are as follows

(1) To establish, confirm, and amplify diagnosis.

(2) To distinguish between functional and organic arterial disease

(3) In the presence of organic disease, to obtain a p knowledge of *a*, the site and extent of any arterial block *b*, the condition of the arterial walls above and below the bloc *c*, the number, size, and position of collateral vessels, *d*, the patency and function of the arterial tree beyond the bloc with particular reference to the potential blood supply of th skin and muscles.

(4) To plan treatment

(5) To aid prognosis

Methods of Investigation

Arterial Pulsation

The Pachon oscillometer was used at mid thi mid calf levels and above the ankle

Skin Blood-flow

The response of skin-temperature to indirect-h was measured by the method of Lewis and Pick (1931) Skin temperature readings of the big toe, made on a Cambridge thermocouple skin thermom

Venous-occlusion plethysmography of the foot was done by the method of Barcroft and Edholm (1943)

Fluorescein-circulation rate was determined by the method of McGregor and Wayne (1951) and Goodwin and Kaplan (1951)

Calf-muscle Blood-flow

Venous-occlusion plethysmography was done before and after two minutes' exercise taken under conditions of temporary arterial occlusion.

Arteriography

This was done by percutaneous injection of 50% Diodone into the femoral artery at the groin, followed by serial radiography of the whole limb The details of the radiological technique have been described elsewhere (Jones and Steiner 1949)

All the investigations were made in the laboratory at a room temperature of 19·0–23·5°C.

ARTERIOGRAPHY

Although it is our object to assess the value of our methods in the light of our aims of investigation, if these methods are also to be compared and contrasted some common basis of comparison must be agreed on, In our opinion the only satisfactory basis for this purpose is an anatomical one Of the methods we used arteriography is the only one which enabled an anatomical analysis to be made of the disease process in the arteries of the legs we studied In view of this we used it as a standard by which to compare and contrast our other methods of investigation We relied on a pictorial rather than a quantitative assessment of arteriography, and the standards by which we assessed the arteriograms (fig 1) have been as follows:

(1) *The presence of disease shown by atheroma or by thrombosis.*

(2) *The collateral circulation, judged by the number size, and tortuosity of the collateral vessels and the filling of the distal arterial tree.*—A *good* collateral circulation was inferred from rapid filling of the main arteries beyond the block, through a satisfactory number of collateral vessels. A *fair* collateral circulation was inferred from delayed filling of the main arteries beyond the block through a few collateral channels. A *bad* collateral circulation was inferred from patchy filling or non filling of the main arteries beyond the block through very few collateral channels.

(3) *The circulation of the foot judged by the patency or absence of the dorsalis pedis and plantar arteries.*—We have accepted filling of both the dorsalis pedis and plantar arterial arches as indicating a good blood-supply to the foot, provided the collateral circulation round any proximal blocks was good When there was only partial filling of the plantar and dorsalis pedis arteries, the foot circulation was assessed as fair particularly if blocks were also present in the tibial and/or the peroneal arteries When the plantar vessels failed to fill the circulation was considered to be bad. In this connection it must be remembered that the dorsalis pedis artery is absent in about 8% of normal persons (Allen et al. 1940) Early venous filling on arteriography was accepted as evidence of a good collateral circulation and of a good blood-supply to the foot.

TABLE I—RELATIONSHIP BETWEEN AVERAGE OSCILLOMETRIC (PACHON) DEFLECTIONS AND ARTERIAL PATENCY DEMONSTRATED ARTERIOGRAPHICALLY

Level of application of oscillometer to limb	Major arterial thromboses absent	Thrombosis in femoral or popliteal artery		
		Tibial and peroneal arteries patent	One or more major distal thromboses	Total
Mid-calf	5	1·1	1·1	1·1
Ankle	2	0·6	0·6	0·6

Figures represent average oscillometric deflections.

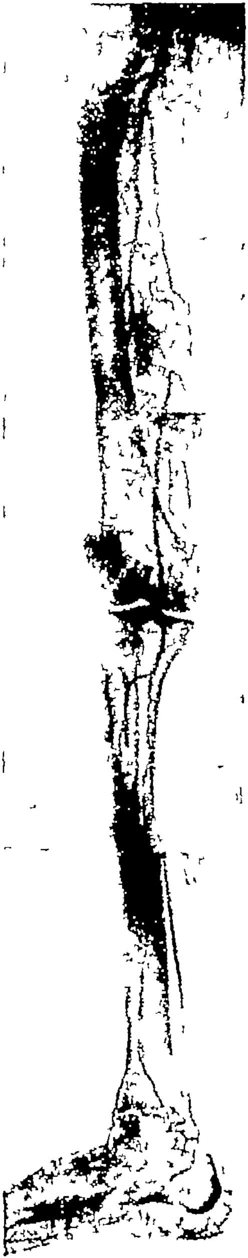

Fig. 1—Arteriogram of right leg in a man, aged 31 showing thrombosis of superficial femoral artery good collateral circulation, patency of distal arteries and good circulation in foot.

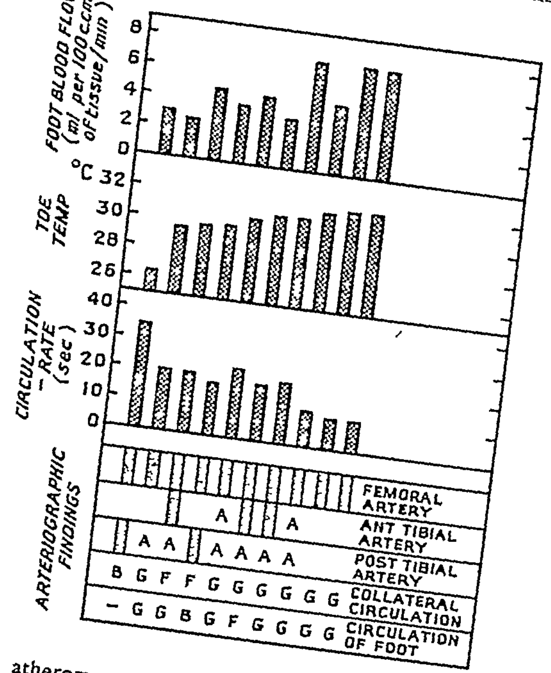
OSCILLOMETRY

A comparison has been made between the anatomical distribution of distal arterial thromboses beyond a femoral or popliteal block and the average oscillometric readings at mid-calf and ankle level in the same series of patients (table I) It is apparent that the presence of filling or obstruction of the tibial and peroneal arteries does not influence the average oscillometric readings in such circumstances

We have found that there is no constant relationship between the resting foot and calf flows and the oscillometric readings at mid-calf and ankle levels. This confirms the findings of Edholm et al. (1951) who showed that oscillometric readings measured by a cuff method give no indication of blood flow because the force of arterial pulsation may be inadequate to overcome the cuff pressure

Oscillometry is therefore of use only in diagnosing the level of the block, and of least value in assessing the collateral supply and patency of the main arteries beyond the block Early disease of the arteries before the occurrence of thrombosis is not demonstrated Localisation is not accurate enough to be of use for arterial grafting or for thrombectomy nor is the decision for or against lumbar sympathectomy influenced by the oscillometric findings, because these give no indication of skin flow Oscillometry has only limited value in deciding the level of amputation



A, atheroma present. B, bad F, fair G, good
Stippled columns, thrombosis

Fig 2—Foot blood-flow, toe-temperature, circulation rate and arteriographic findings in 10 cases of femoral artery thrombosis. Arranged in ascending order of toe-temperatures

FLUORESCEIN CIRCULATION RATE

This test was made, after indirect heating, by the method of McGregor and Wayne (1951) and Goodwin and Kaplan (1951)

In the presence of a femoral artery block, shown by arteriography, there was reasonably good correlation between the circulation-rate, on the one hand, and toe temperatures after indirect heating and foot blood flow measured by plethysmography on the other (fig 2) Limbs with a femoral block and good collateral circulation tended to have a short circulation time and high toe temperatures, but the converse was not necessarily true When all cases were considered together, only fair correlation was found between circulation rates, on the one hand, and foot blood flows and toe temperatures on the other (fig 3)

Measurement of the circulation rate, even when a substance with an objective end point is used, is not a particularly sensitive indicator of peripheral blood flow When the disease mainly involves the digital vessels, toe temperature recordings may not correlate with the circulation rate, which has been measured only as far as the dorsum of the foot Moreover we have found digital gangrene in the presence of palpable ankle pulses and good foot blood flow, in such cases it is not surprising to find the circulation rate normal The correlation between toe temperatures and circulation-rates in 10 limbs with femoral artery block (fig 2) is similar to that found by Goodwin and Kaplan (1951)—agreement between temperature readings for the skin of the calf and toes and fluorescein circulation times in 12 patients, most of whom had major arterial blocks. Th resence of normal skin temperatures an l finding in patients with organic se. ted by Pickering (1933), and

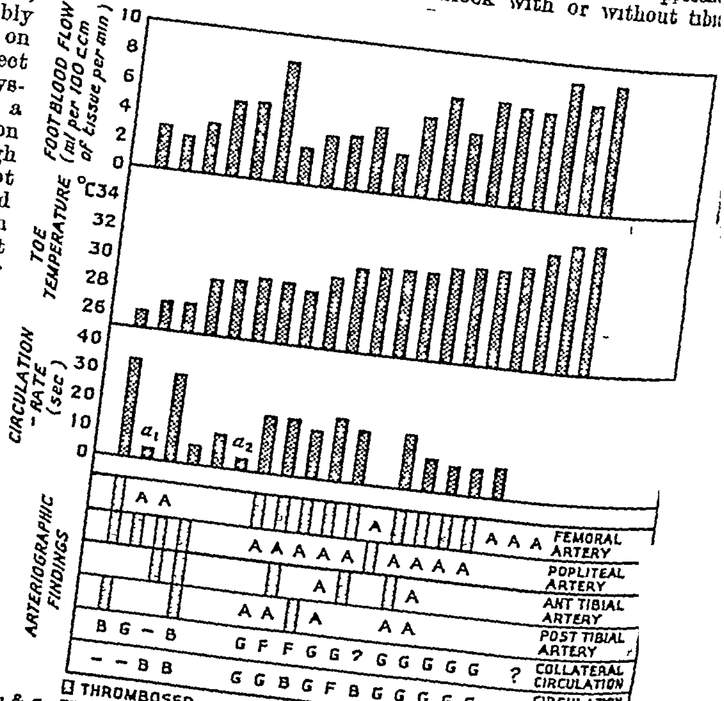
McGregor and Wayne (1951) occasionally noted normal fluorescein-times in such patients

FOOT PLETHYSMOGRAPHY AND TOE-TEMPERATURE RECORDINGS

Since little information can be obtained by examination under resting conditions, vasoconstrictor tone must be released before the efficiency of the circulation of the lower limbs can be studied Pickering (1933) showed that the temperature of an affected limb at rest may be increased above that of its relatively normal fellow Furthermore, recording of normal blood-flow does not indicate that the tissues are receiving an adequate bloc supply, because there may be deviation through arteriol venous anastomoses, the blood supply never reaching th capillaries (Abramson 1944)

We have obtained indirect vasodilatation of the lowe limb by the method of Lewis and Pickering (1931) We have measured the degree of vasomotor release obtained by recording the increase in the foot blood flow and in the temperature of the dorsum of the great toe, using an air filled venous occlusion plethysmograph and the Cambridge thermocouple thermometer

The relationship between foot blood flow after indirect vasodilatation and the anatomical lesion shown by arteriography is shown in table II 42 limbs were analysed, and the foot blood flows are presented in the table as an average for each group of anatomical lesions. Where thrombosis (but not necessarily disease) is absent, the average maximal foot blood flow measured 9 ml per 100 c cm of tissue per minute With a femoral or popliteal thrombosis but patency of all the major distal arteries, the average maximal blood flow was 5 2 ml The presence of an additional block in one or more of the tibial arteries led to a further reduction in the average maximal foot blood-flow to 3 9 ml If the last two groups are considered together—i e , in the presen of a femoral or popliteal block with or without tibi



□ THROMBOSED A, ATHEROMA PRESENT B, BAD F, FAIR G GOOD

Fig 3—Foot blood flow toe-temperature circulation-rate and arteriographic findings in 20 cases of obliterative arterial disease of the lower limb (all types). Arranged in ascending order of toe-temperatures.

TABLE II—FOOT BLOOD FLOW AND TOE TEMPERATURE AFTER INDIRECT HEATING IN RELATION TO ANATOMICAL FINDINGS BY ARTERIOGRAPHY

Anatomical sites of arterial thromboses shown by arteriography	Foot blood flow after indirect heating (ml per c.cm. of tissue per min.)		Average maximal toe temperature after indirect heating (°C) (normal = 33°C or more)
	Average maximum for each group	Range of maximum over each group	
All major vessels patent	9·0	5·1–13·5	32·0
Femoral or popliteal with or without tibial	4·0	2·5–7·2	31·0
Femoral or popliteal only	5·2		
Femoral or popliteal with one or more tibial	3·0		
Femoral or popliteal with one or more tibial and either or both plantar and dorsalis pedis	3·3	2·3–5·0	28·5
Tibial with or without either or both plantar and dorsalis pedis	5·5	2·8–8·5	32·0
Tibial only	5·5		
Tibial and plantar and/or dorsalis pedis	5·4		
Dorsalis pedis and/or plantar only	7·5		

thrombosis—the average maximal foot blood flow was 4·0 ml. In the presence of superadded thrombosis of the dorsalis pedis and/or the plantar arteries the foot blood flow was further reduced to 3·3 ml. Where the thrombosis was confined to the tibial and peroneal arteries the average foot blood flow was 5·5 ml. and the presence or absence of additional blocks in the main arteries of the foot did not seem materially to affect blood flow in the foot.

The average toe temperature for each group is also recorded in table II. In our experience the average toe-temperature reached in normal people after vasodilatation has been 33–34°C. It will be seen that a difference of only 1°C was recorded between the average maximal toe temperatures in normal limbs and in those limbs in which atheroma but no actual thrombosis was present. A similar difference was found between the latter group and limbs with femoral artery thrombosis without additional blocks. It is only when there were additional blocks beyond the femoral and popliteal arteries that there was a significant drop of 2–5°C in the toe-temperature after the indirect heating. Toe temperatures are thus less helpful in diagnosis than are measurements of foot blood flow; but, if a major block of the femoral or popliteal artery is present, a failure of the toe temperature to reach 30°C after indirect heating strongly suggests the presence of additional distal blocks.

It must be emphasised that these figures are averages, and there is a wide range between the maximum and minimum in each group, presumably owing to variations in the anatomical lesion, the collateral supply, the degree of vasomotor release, &c. It is therefore impossible to discover the degree of ischæmia present in the foot by measurement of the foot blood flow after indirect vasodilatation, and only when the sites of the main arterial blocks are known is it possible to interpret the foot blood flow as above or below the average for that group of patients. In our experience these measurements do not necessarily bear any relation to digital gangrene which may be established even though the peripheral pulses may be palpable and the foot blood flow within the normal range.

The relationship between foot blood flow and the anatomical lesion shown by arteriography clearly indicates that the foot blood flow may be approximately assessed from the arteriogram.

As has been mentioned, we have compared circulation rates, toe temperatures, and foot blood flows, and fig. 2 shows that, although a correlation between these tests is evident in limbs with a femoral-artery thrombosis, the correlation is less convincing when all the cases are considered together (fig. 3).

The direct comparison between foot blood flows and toe temperatures (fig. 4) shows that correlation is fair when all types of cases are considered and good in cases having femoral artery blocks only.

Return of vasomotor tone after sympathectomy was first noticed by Lewis and Landis (1930) and Lynn and Barcroft (1950) showed that the resting blood flow in the foot had returned to within twice the preoperative level within seven days. From our own experience, and from a study of their paper it is apparent that no relation exists between the preoperative maximal foot blood flow after indirect vasodilatation and the ultimate resting foot blood flow after lumbar sympathectomy. It is therefore difficult to gain by preoperative tests anything but an impression of the results to be expected after sympathectomy. The nearest approach to accuracy is that a patient should show clinical improvement. Because a direct approach to the vessel is still of limited application, surgery has little to offer these patients other than sympathectomy as a prophylaxis against gangrene, and in our experience preoperative investigation seldom influences the decision for or against this operation. In general, it can be said that a good clinical assessment is sufficient for other than academic purposes.

CALF PLETHYSMOGRAPHY AFTER EXERCISE

Resting calf blood flows are of no significance in the accurate assessment of the potential blood-supply to the muscles of the calf, the measurement of which has always presented difficulty. Various methods have been used: for example, Boyd et al. (1949) use a claudicometer designed to measure the onset of claudication at a controlled speed of walking over measured distances. Various forms of ergometer have been devised (Shepherd 1950, Simmonds 1936, Hitzrot et al. 1936).

We have used the venous occlusion plethysmograph filled with water at 34°C to measure the calf blood flow

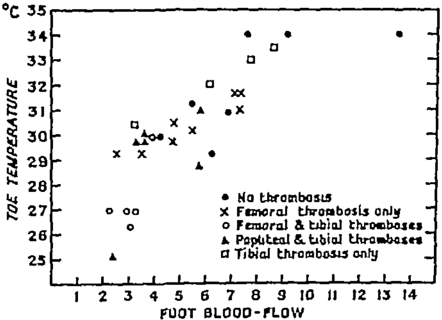

Fig. 4—Correlation of foot blood-flow and toe-temperature after indirect heating (30 limbs).

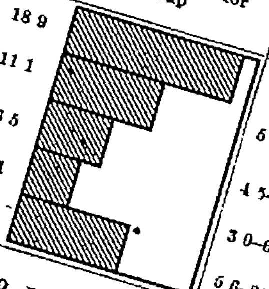
TABLE III—CALF BLOOD FLOW AFTER EXERCISE IN RELATION TO ANATOMICAL FINDINGS BY ARTERIOGRAPHY



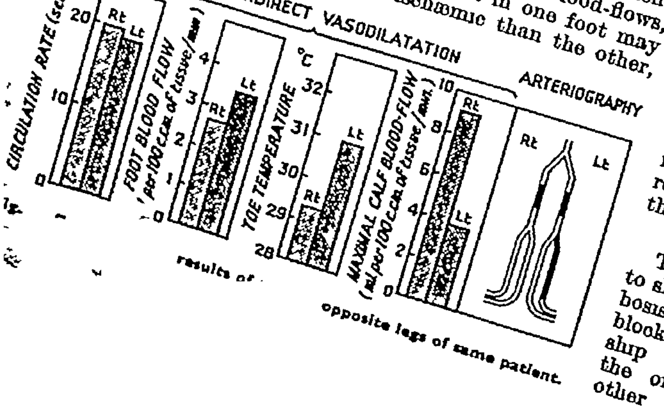
Anatomical sites of arterial thromboses shown by arteriography	Calf blood flow after exercise (ml per c.cm of tissue per min) Average maximum for each group	Range of maximum over each group	Return of calf blood-flow to within 1 ml. of resting range (min.)
All major vessels patent	18·9	9·0–26·0	5·0
Femoral only	11·1	6·3–19·0	7·5
Femoral and tibial	6·5	4·5–11·5	6·5
Popliteal and tibial	5·1	3·0–6·7	5·2
Tibial only	11·9	5·6–22·0	4·0

before and after two minutes of graduated exercise taken under conditions of temporary arterial occlusion.

In the analysis and interpretation of the results obtained from this test three variables have to be considered (1) the maximal blood-flow obtained, (2) the time required after exercise to reach this peak 'blood flow—vasodilatation in muscle is already full at the end of a period of arterial occlusion (Lewis and Grant 1925), and (3) the time taken for the calf blood-flow to return to within the resting range. In table III the anatomical site of the arterial lesion shown arteriographically is compared with the maximal calf blood-flow obtained after exercise. The highest average flow of 18·9 ml per 100 c cm of tissue per minute was obtained when thrombosis in the major arteries, but not necessarily disease, was absent. With femoral arterial thrombosis alone the average peak calf blood flow was 11·1 ml, and, when the lesion was peripheral to the popliteal bifurcation only, the average peak blood-flow was 11·9 ml. The combination of femoral and peripheral thrombosis reduced the average maximal calf blood flow to 6·5 ml, and in those limbs in which peripheral arterial blocks were associated with a popliteal thrombosis 5·1 ml, the lowest reading in all the groups, was recorded. This is not surprising, because it is in these cases that the origin of the sural arteries is most often involved in the disease.

The range between the highest and the lowest maximal calf blood flows in each group is also recorded. As with foot blood flows after vasodilatation, this range is wide, particularly where there are no blocks, or when the block is limited to femoral or peripheral arteries alone.

This pattern is similar to that followed by foot blood flows after vasodilatation, but we have been unable to find any definite relationship between these and the maximal calf blood-flows obtained after exercise. Indeed, in comparing contralateral limbs in the same patient (fig 5) we have found that, whereas foot blood-flows, toe temperatures, and circulation-rates in one foot may suggest that limb to be more ischæmic than the other,



results of

opposite legs of same patient.

the calf blood-flows after exercise have indicat reverse. In this case the arteriographic finding with the calf blood-flows, and we believe that blood flow after exercise is a better index of the circulation of a limb than are methods invo measurement of vasodilatation in the foot.

The delay in reaching maximal calf blood-flo exercise is found only with femoral or higher, and may well be of artificial origin. Neverthel practice it has been found that the longer the dela less efficient is the collateral circulation.

It has been shown by Grant (1937) that, after an rapid return towards the resting blood flow, the blood-flow after exercise may remain at a level 1 ml per 100 c cm of tissue per minute of the resting blood-flow for as long as twenty minutes have confirmed this, and in our analysis of calf blood flows after exercise it has been thought advisable accept a return to within 1 ml. of the previous blood-flow as the point of return to normal. In table these figures have been arranged for each group of but the only significant fact that emerges is is a longer delay in femoral arterial blocks either or without additional peripheral blocks than in or tibial blocks.

Conclusions

It is clear from our attempts to compare these of investigation that in obliterative arterial disease,

TABLE IV—ASSESSMENT OF VALUE OF TESTS USED INVESTIGATING PERIPHERAL VASCULAR DISEASE OF LOWER LIMB

	Diagnosis and assessment of circulation						Influence on choice of treatment		
	Level and extent of block	Collateral system	Condition of arterial walls	Patency of main peripheral arteries beyond block	Potential skin blood flow	Potential muscle blood flow	Lumbar sympathectomy	Grafting, &c.	Level of amputation
Clinical history and examination	Yes	Yes	Yes	No	Yes	Yes	Yes	No	Yes
Oscillometer (Pachon)	Yes	No	No	No	No	No	No	No	Yes
Tests measuring vasodilatation									
Toe-temperature	No	Yes	No	Yes	Yes	No	No	No	No
Circulation rate	No	Yes	No	Yes	Yes	No	No	No	No
Foot plethysmography	No	Yes	No	Yes	Yes	No	No	No	No
Calf plethysmography after exercise	No	Yes	No	No	No	Yes	No	No	No
Arteriography	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes

Yes of value No of no value.

two limbs are alike, the variety of anatomical lesions infinite and the overlay of vasomotor control never th same. We have shown that a quantitative control is limited in its application unless exact anatomical correlation tions are known. Bearing this in mind, we have marised (table IV) the value of the tests we have sum regards the aims of the investigation which we stated the outset.

OSCILLOMETRY

This is of no help in clinical assessment other than to show the upper limit of the level of an arterial throm bosis. Assessment of prevailing conditions below the block is impossible, because there is no constant relation ship between arterial patency and blood-flow, on the one hand, and oscillometric deflections, on the other

Comparisons can only be made between contralateral mbs in the same patient, and not between one patient nd another

As regards treatment, oscillometry is perhaps of mited value in assessing the level of amputation

TESTS OF VASOMOTOR RELEASE

oe-temperature Foot Plethysmography and Fluorescein rculation Rate

The measurement of toe temperatures has proved to e the best method of assessing an individual digit ut may bear no relationship to proximal conditions of rterial competency and any correlation between the wo can only be applied in its widest sense.

Foot blood flows provide the best assessment of the lood-supply to the foot, and a definite relationship etween this and the anatomical lesion has been shown The correlation between foot blood flows and toe emperatures is approximate, and is greatest in femoral hrombosis uncomplicated by distal blocks.

We consider that the fluorescein-circulation rate is slightly inferior test to toe temperature recordings, xcept when a femoral block is present, in which case igh skin temperatures and a short circulation rate uggest a good collateral blood supply The circulation ate is of no value in determining the presence or absence of a thrombosis in a major vessel.

It therefore follows that the interpretation of these methods as a quantitative method of investigation s only acceptable if the exact anatomical lesions are nown, and even then the technical limitations of the tests must be taken into account

As regards clinical assessment no information is obtained about the level of the block and early disease s not discovered, assessment of the collateral system and patency of the arterial tree is indirect and limited n application

It is our opinion that tests of release of vasomotor one, though important for physiological research, are of little clinical value in the accurate assessment of pathological conditions. As regards treatment, we do not consider that the results of these tests influence the decision for or against any form of surgical operation

Calf Plethysmography

Although this gives a better idea of total blood supply to the limb than do tests of vasodilatation it is of little clinical value and certainly of no value as a guide to treatment. Direct correlation cannot be made between calf and foot blood flows.

ARTERIOGRAPHY

This is the only method which allows an accurate assessment of the presence of early disease, the level and length of the block, the condition of the arterial wall and patency beyond the block The collateral supply cannot be quantitatively estimated but a study of the number calibre and tortuosity of the vessels gives valuable information The skin blood flow may be judged approximately and a relationship of the origin of muscular vessels to the site of disease is of significance (fig 1)

As regards treatment, arteriography is of little value in the selection of patients for sympathectomy but essential if direct arterial surgery is contemplated. It is very useful in decisions about the level of amputation

Arteriography should not be used as a routine but reserved for (1) confirmation of early organic disease (2) cases in which direct surgical intervention on the artery is a possibility, and (3) a preliminary to amputation in certain patients.

From a practical point of view it cannot be too strongly emphasised that a careful analysis of the clinical history and examination will provide as adequate a guide to treatment as, if not a better one than, any method of special investigation (except when direct surgical intervention on the artery is contemplated) If additional information is required arteriography is the method of choice

In the investigation of peripheral vascular disease it is a common habit to focus attention as we have done here, on an attempt to assess disturbances of function As we have shown little information is gained which is of value in selecting the type of treatment required Further work will be necessary to correlate these diagnostic tests with the results of treatment and thus to assess their value in this connection.

We are grateful to Dr O G Edholm for his help and advice

REFLECTIONS ON DIABETES MELLITUS

ANSWERS TO A QUESTIONARY

G F Walker
M.D Leeds, F.R F.P S M.R C.P D C.H.
CONSULTANT PHYSICIAN PETERBOROUGH AND DISTRICT HOSPITALS

Musing upon the literature of diabetes mellitus recently I was struck by much conflicting evidence Whittaker (1949) writing on the handling of diabetic children condemns the notion that insulin treatment with free" diet will give adequate control, pointing out that children treated in this way are ill grown and undernourished, alternating between hyperglycæmia with symptoms and severe insulin reactions. Goadby (1950) found evidence in a carefully observed series of 43 patients, that unrestricted carbohydrate diet with insulin did not harm the patients and tended to reduce ketonuria. Goadby and Jacobs (1950) as a result of a pilot survey have propounded a hypothesis as follows

> (1) The control of diabetes mellitus as practised in the light of present knowledge, is without effect on the incidence of the long term complications of hypertension retinal and lens changes, and vascular disease
>
> (2) The control of diabetes does influence the incidence of neuropathy
>
> (3) In controlling the sugar metabolism we are not treating the underlying pathological condition which causes both the metabolic defect and the vascular and eye changes which may accompany it.

Jackson et al. (1950) believe that in children, a high level of control is not only possible but is the best form of preventing or delaying chronic degenerative changes. Root et al (1950) think that poor control and the duration and severity of the disease all play a part in promoting the onset of degenerative processes in diabetes and that it is impossible to apportion the blame with any accuracy Hunt (1951) in an impressive paper based upon vast personal experience pours scorn upon any kind of dietetic regimen for a diabetic, except one who is too fat On the other hand Wilson et al (1951a) believe that dietetic control is more important than any other known factor, such as duration or severity, in preventing degenerative vascular complications, and Spoont et al (1951) produced evidence showing that poorly controlled diabetics are more prone to retinopathy than well controlled patients, but they shrewdly point out that the evaluation of the degree of diabetic control is difficult

Wilson et al (1951b) give a good working classification of what they understand by "excellent," "good," "fair," and "poor" control, and they believe that any guidance falling short of good control permits diabetic nephropathy They describe 37 patients, in a series of 247, who maintained excellent or good control for a long time and escaped nephropathy Beaser (1951), in a survey similar to that of Wilson et al, found a similar response in a larger group of patients Wilson et al (1951c) compared two groups of young diabetics one group was controlled by a careful adherence to diet and normoglycæmia, the other was on a "free" diet with sufficient insulin to ensure health despite steady hyperglycæmia The first group was less susceptible to complications than the second, but by no means exempt

Among the other evidence, Zubrod et al (1951) believe that the onset of Kimmelstiel Wilson lesions coincides with a change in the character of diabetes of such a degree that progressively less insulin may be needed Hall (1952) thinks that glomerulosclerosis is one manifestation of a generalised vascular degeneration in diabetic patients and that duration and poor control both promote this process Lawrence (1952) has formulated rules, arising from his very great experience, for the guidance of diabetics who drive vehicles upon the roads Keiding et al (1952) believe, as a result of really substantial work, that good control of diabetes is more important than any other factor in the prevention of complications Hinkle and Wolf (1952) in an admirable survey bring out well the importance of stress and strain, as compared with relaxation and security, in the assessment, fluctuations, and day-to-day management of diabetics

With all this in mind I sent a questionary to 142 physicians, like myself, in charge of diabetic clinics, asking them a number of simple looking questions, and this is the result

The Questionary

The questionary itself brought the following response

Prompt replies	66
Delayed replies	15
Regret inability to help	6
Curt refusals	2
No replies	53
	142

Most of the replies were generously informative, often running into many sheets of closely written manuscript

I thus found myself with 81 reports on the modern handling of diabetes mellitus in clinics up and down the country, and the results can be condensed thus

Question (*a*) —Replies to preliminary questions showed that about 75% of all patients attending our clinics use insulin.

Care and Accuracy of Patients

Question (*b*) —What proportion of your patients taking insulin satisfy you that they are careful and accurate ?

All	6
Most	45
Probably about two thirds of them	11
Less than half	6
Difficult to assess	13
	81

Two physicians wrote

"The m[illegible]y of patients measure the insulin correctly but do [illegible] diet restrictions at all accurately, nor are they particularly careful in the care of their syringes and needles."

"I think probably 75–80% are accurate and careful, but I have to be very searching in questioning them Periodically I find that owing to the different strengths, patients are taking half or double the number of units I believe them to be taking In these cases if the follow up tests are satisfactory I simply discuss how many marks on the syringe they should take"

Hyperglycæmia or Normoglycæmia ?

Question (*c*) —Do you believe in mild hyperglycæmic control or normoglycæmic control ?

Normoglycæmia (including 2 emphatically)	26
Mild hyperglycæmia (including 2 emphatically)	38
Does not believe normoglycæmic control possible	1
We aim at normoglycæmia but usually have to be satisfied with mild hyperglycæmia	11
It depends on individual needs	4
Indecisive reply	1
	81

The answers included the following

"We prefer our diabetics who are taking insulin to pass a little sugar in their water, and are satisfied as long as their blood sugars are below about 200 mg per 100 ml and *there is no ketonuria*"

"The answer is 'it all depends upon the patient' Naturally I like them to be as near normoglycæmic as possible, but in many of the severe cases we have to be content with mild hyperglycæmic control so as to avoid hypoglycæmic reactions"

"I believe emphatically in normoglycæmic control, and am equally strongly against mild hyperglycæmic control, unless there is some good reason for it, such as a low renal threshold."

Carbohydrate Consumption

Question (*d*) —If you prescribe a diet, how many grammes of carbohydrate do you think adequate for a man of 140 lb ?

Between 200 and 300	16
About 200	20
About 150	9
Between 150 and 200	10
Depends on his work	20
About 120	2
No diet is prescribed	3
Not applicable (children's clinic)	1
	81

Some of the points made in replies were

"Where insulin is taken the diet is approximately 200 g of carbohydrate daily Non insulin takers are given 100 g a day as a minimum"

"Elaborate calculations are not used Not less than 160 g —but the final decision is based on appetite, type of work, and weight"

"We prescribe diets here in calories rather than in grammes of carbohydrate, but our 2500 calorie diet, which is the one most frequently used, contains 280 g of carbohydrate"

"In prescribing amounts of carbohydrate, I am guided, on the whole, not by consideration of how much carbohydrate a man of a given weight should take, but more on whether the patient is under or overweight If significantly over weight then the patient is placed on a reducing diet, usually containing from 100 to 140 g of carbohydrate If underweight, or of average weight, then in a great majority of cases carbohydrate is prescribed according to his wishes, the dose of insulin, if necessary, being adjusted. Himsworth's work some years ago would suggest that, in people of normal weight, diet should contain at least 200 g of carbohydrate as lesser amounts tend to alter their insulin sensitivity"

Adherence to Diet

Question (*e*) —What proportion of your patients taking a diet satisfy you that they adhere to it reasonably well ?

All or nearly all	4
The great majority	37
About half	22
The minority	5
Very few	7
Not applicable	1
Unanswered	5
	81

The following statements represent the views expressed:

Of the mild obese diabetics, approximately 50% adhere satisfactorily to the diet. Of the others a considerable proportion only diet sufficiently to relieve symptoms.'

The majority of patients on insulin adhere to the diet reasonably well. If they do not ketosis and pre-coma betray their backsliding but this is unusual The obese patient, whom I always attempt to control without insulin, is a more difficult problem, although once having lost weight the improvement in their sense of well being and appearance will impress on them that diet restriction is worth while '

It is almost impossible to say how many patients really do adhere to their diet. I feel it is probably only a small proportion who keep strictly to it, but gross excesses are rare, except in the cases of those who are on a 1000-calorie reducing diet and yet continue to gain weight.

" Almost all patients lie as regards keeping their diet."

"The great majority I am sure take a steady diet. The English man and woman are very conservative and once they get into a routine with no sugar or sweet food I don t think they alter much except on specific occasions, such as weddings when they generally ask for advice before There are of course some—especially young people and children—who run away with sweets and puddings, but on the whole if they have enough to eat and are not hungry, I don t think they do so'

Complications

Question (*f*)—Do you think there is any connection between hyperglycæmia and the complications of diabetes such as retinitis, cataract, gangrene nephritis and phthisis?

Comprehensive yes	30
Comprehensive no	6
Don't know	18
Unanswered	3
Yes, but unsure of the evidence	6
Yes, but uncertain about phthisis	9
Yes but uncertain about cataract	2
Yes, but uncertain about nephritis	5
These maladies appear to be independent of the degree of control imposed	2
	81

The answers included these remarks

There is no doubt that there are some elderly conscientious and intelligent patients who develop these complications irrespective of their diabetic control I am beginning to think that nephritis is commoner in the long standing diabetic who has not been ideally stabilised.'

"Yes: though it is my experience that in gangrene the body weight is more important—i.e., fat patients are more likely to get gangrene

I am quite sure a tight normoglycæmic control is essential in patients with phthisis and those patients presenting with retinitis, cataract gangrene and nephritis are usually those who have been inadequately controlled in the past. I believe that hyperglycæmia should be prevented if possible

"I am absolutely certain there is no connection between hyperglycæmia and retinitis, cataracts, and nephritis. There is an undoubted connection between hyperglycæmia and gangrene phthisis, and neuritis.

I cannot convince myself that there is a real connection between hyperglycæmia and the diabetic arteriosclerotic complications. Phthisis I do think is more liable to occur in an uncontrolled diabetic than in a normal young person

Strictness of Diet

Question (*g*)—Do you teach strict dietetic regimen or do you condone a certain laxity in a prescribed diet or do you allow a completely free diet regulated by insulin?

Strict dietetic regimen is taught	37
Laxity in a prescribed diet is condoned	27
Free diet regulated by insulin is our plan in many cases	3
We teach strict diet in young people and allow laxity in other patients	8
My policy varies with each patient	4
There is no such thing as a "free" diet	2
	81

Here again much diversity was evident:

"Patients are certainly taught strict dietary régime with carbohydrate intake balanced against regular insulin.'

"I teach strict dietetic regimen and allow no laxity I certainly do not teach a strict dietetic regimen I do however, insist that no sugar or sweet food should be taken because I think that it is absorbed into the blood so quickly that it upsets the balance I try to adapt the diet to the patient s ordinary meals and general way of life."

"We do not teach a strict dietetic regimen, except in certain of the cases requiring insulin The rest are given instructions about their diet and a diet sheet as a guide and some patients, such as heavy workers, take a free diet covered by an adequate dose of insulin.'

I allow a free diet with the exception of actual sugar

'I find that the majority of young diabetics require a fairly strict prescribed diet. Over 35 provided the diabetes is not very severe I allow a modified free diet—i.e. no sugar jam sweets, chocolate or potatoes, and limited bread and cake. I find with a simple diet on these lines one gets more coöperation and I am satisfied the patients take it much better than if they are on a very strict diet, to which I feel they seldom adhere.

We teach a strict carbohydrate control. The protein can look after itself and in fact, few patients can be encouraged to take enough fat Many patients adopt a completely free diet in spite of our advice and where this is regulated by insulin there is a considerable weight increase amounting to sometimes a stone a year I think a completely free diet is wrong, even in children.'

Yes: a strict dietetic régime with a fixed daily amount of carbohydrate Laxity certainly not, but freedom yes. Freedom from too small a diet. Many of our diets for a working man will contain between 200 and 300 g of carbohydrate so approaching the figure described as a free diet. As so many patients will take a liberty if given the slightest encouragement, even on generous diets the attitude of laxity is never encouraged

I advise a strict dietetic régime for all the younger and more severe diabetics, although I use a list of food exchanges to get a considerable variety in the diet. I do not think it matters much with old and mild diabetics, as long as one keeps them slim. I cannot get adequate control with a completely free diet and insulin without hypoglycæmic accidents.'

Testing of Urine

Question (*h*)—Do you encourage your patients to test their own urine at home?

The answers were almost equally divided between 'Yes' and No.'

Typical answers were:

I only encourage those people to test their urine at home who are insulin-sensitive and in whom I want information about the causes for any instability Most hospital patients do more harm than good by testing urine! In any case they do not realise that the renal threshold varies very much and they worry unnecessarily if they have a low threshold."

'I insist that all patients test their own urine at home, not only for sugar but in many cases for ketones as well.

If the patients do not test their own urine we arrange for the District Nurse to do so Otherwise how can there be any day to-day control of a diabetic?'

"On the whole we do not encourage patients to test their urine unless we are rather apprehensive about hypoglycæmic attacks, when, after a succession of [illegible] tests of the urine we get them to attend again [illegible] blood sugar, and lower the dose I have found it of value in people who are not sticking to their diet when a [illegible] of red tests will alarm them and make them [illegible] better"

Driving of Vehicles

Question (*i*).—Do [illegible] patients taking insulin drive public service [illegible] vans, [illegible] engines, tractors, [illegible]

Comprehensive yes
Comprehensive no
Qualified [illegible]
Not a [illegible]
No [illegible]
Di[illegible]

[illegible] Lawrence [illegible]

[illegible]

In London I believe it is a principle that no public-service vehicles may be driven by a diabetic receiving insulin, however well controlled, and the same applies to passenger railway engines However, I have a few engine-drivers engaged on shunting, &c , and many patients drive private cars "

"Among our patients are considerable numbers who drive ublic service vehicles, &c It has always been a matter of anxiety to us, but if they have already been in such employment we take no steps to get them out of it, and curiously enough among all these patients for many years I cannot recall a single fatality as the result. We certainly allow our ordinary diabetic patients to drive private motor-cars."

"There is no question of *allowing* diabetic patients to do these things One is not able to stop them. I have managed to persuade one unstable diabetic to give up driving a charabanc from Oxford to London. My own view is that in an ideal world diabetics on insulin would not be allowed to drive any vehicles "

A Personal Opinion

By good control of diabetes I mean the preservation of wiry and spare physique with an alert and virile emperament as the first consideration Moreover, the patient's fellow workers should be unaware that he or she is a diabetic There should be no diminution of activity in work or play and the metabolic regulation should ensure that there is complete freedom from ketosis and not more than a trace of sugar in the early morning urine The blood-sugar fluctuations throughout the day should correspond to the normal fluctuations, meaning that the blood-sugar at 11 30 A.M. should be between 100 and 150 mg per 100 ml There must be complete freedom from hypoglycæmic symptoms and physical examination must be regular and thorough.

The diet must be well within the patient's capacity nd appetite, and it must be palatable, readily obtainble, and consistent with the patient's mode of life oreover, it must be thoroughly understood and the amount of latitude in the diet must be appreciated by every patient The patient must maintain skill and care with diet but he must avoid an obsessional preoccupation with grammes and calories

The optimum weight having been obtained, usually by some reduction in the early days of training, there must not be more than two or three pounds variation through the year

I do not attain this ideal state in all my patients but this is my aim and my plan and my policy

I wage war on loose and inaccurate syringes and I believe the future will bring forth some sort of locking device for a syringe whereby a patient need not peer at markings Alternatively, it may be possible in the future to give insulin by cartridges of different strengths by a 'Mitrex' syringe

With regard to diabetics driving trains, cars, and ublic service vehicles, I believe that a heavy responbility lies upon the employers, who are entitled to full disclosure Very little can be added to Lawrence's rules (Lawrence 1952)

I do not on the whole encourage patients to test their own urine at home, save in very special circumstances I am convinced that the majority of diabetics confuse and harass themselves by home tests I prefer my patients to have thoroughgoing tests fairly frequently by attendance at my clinic, bringing two specimens at each attendance and having blood-sugar tests during the morning

I do not give out any form of standardised instruction card or sheet, but I have devised two sheets which form the basis of my individual teaching One is comparatively umple and shows the patient how to take accurate ortions of bread, sugar, and potatoes per day, together ith simple guidance as to special foodstuffs and a number elementary warnings. My other card is much more borato and enables a severe diabetic, or the parents a , a diet according to my prescription

with considerable nicety and variety. With my second card a most accurate and carefully planned diet given and I believe this is the backbone of the of diabetes mellitus

One last word. When glycosuria is found the should be sent to a clinic at once, before any diet prescribed, so that the diagnosis can be beyond all doubt.

INTRAVENOUS PROCAINE IN THE TREATMENT OF CHEST-WALL IN

P GILROY BEVAN
M.B Birm., F R C S
LATE SENIOR HOUSE OFFICER IN THE CASUALTY DEPARTMENT,
GENERAL HOSPITAL, BIRMINGHAM

PROCAINE has been used intravenously for the of many types of pain, and for various other conditions (Mushin and Rendell-Baker 1949) Nearly always, however, it has been given, by intravenous infusion of a dilute solution, to inpatients. I report here a trial procaine for the relief of pain associated with chest-wall injuries treated in a casualty department The procaine was given by "straight-in" intravenous injection.

First Series

Selection of Cases

Patients were chosen who were having severe pain after injury to the chest wall. The injury was often relatively minor, though some cases of major trauma were also included The pain was of three types—localised to the site of injury, diffusely spread over a wide area of the chest, or referred forwards along the intercostal nerves. In all the cases the pain was dominant and persistent, coughing, inspiration, and movement of the trunk or upper limb were often much restricted.

Technique

The procaine was injected into a vein of the forearm from a 20-ml. syringe. After various modifications, the standard dose adopted for a normal adult was 20 ml. of 1% procaine, with adjustment for age and physique. At first the injections were given slowly over fifteen minutes, but, as speed increased with confidence, the time was reduced to five minutes With stronger solutions or more rapid injection, patients became uncomfortable.

These amounts accord with the optimal dose calculated by Graubard et al. (1948) and named by him 1 procaine unit—4 mg per kg body-weight in twenty min (e g , 250 mg or 25 ml. of 1% procaine in a man weigh 10 st (140 lb)

Safeguards

Procaine has two main toxic effects—namely, co vulsions (which may lead on to respiratory paral and peripheral vascular failure resulting from medullary depression Martin (1928) attributed both these manifestations to idiosyncrasy Measures were taken to counteract these effects if they appeared A special tray was at hand containing thiopentone to antagonise the convulsant action of procaine (Clark 1942) and ephedrine to combat the medullary depression (Isenberger 1949) But in giving 82 injections there was no need to use these drugs.

Each injection was given with the patient recumbent, to counteract the vasodilator effect of procaine He then rested half an hour was reviewed, and was sent home by ambulance He was seen again next day and again a few days later

The procaine was specially prepared in separate sealed 20-ml ampoules with five-day tests of sterility and contained no adrenaline or bacteriostatic

Therapeutic Effects

The injections gave considerable relief to the great majority of patients. The pain was reduced and the general condition improved.

The degree of local relief was estimated by watching the patient, by asking him to describe any change in his symptoms, and by measuring the maximum respiratory excursion before and after injection

The pain seemed to be relieved in stages. Many cases enjoyed *immediate* relief during or immediately after injection. Others experienced *delayed* relief hours later A third group found *continued* relief during and for many hours after injection

The duration of relief varied from two- to forty-eight hours or even longer in some cases the pain never returned. On the average the pain was relieved for twenty hours, and then returned in a much milder form In some cases a second injection was given a few days later but it always seemed less effective

The main relief was usually in the diffuse severe pain occurring over a wide area. After injection the patient could breathe deeply move freely and cough Many were helped to a full night's sleep and could resume work The pain that remained or returned later was always milder localised to the site of injury and susceptible to local methods of relief

The general condition improved beyond what might be expected purely from the alleviation of pain Patients lost their depression and became cheerful or even frankly euphoric This effect was often associated with immediate relief of pain

Thus procaine may act both centrally on the cerebral centres—an immediate effect—and peripherally by direct action at the site of trauma giving delayed relief

Toxic Effects

About half the patients experienced mild discomfort —e.g dizziness, a feeling of warmth or burning all over a feeling of numbness or deadness, twitchings in the muscles, or temporary loss of the power of speech. These symptoms seemed to be related to the speed of the injection and never lasted more than a few minutes. One patient lost consciousness, at the end of the injection for about two minutes but was none the worse after consciousness returned

No evidence of a delayed toxic action was found in the sample of patients followed up for a year

Physiological Effects

The pulse-rate was found to slow by an average of 8–10 beats per minute during the injection, but there was no change in volume. The blood pressure fell by an average of 10 mm Hg systolic and 5 mm. diastolic the fall being proportionally the same in 2 established hypertensives. Vasodilatation of the cutaneous vessels commonly showed as generalised flushing towards the end of the injection, associated with a feeling of warmth, and in these cases there was a rise of 1–2°F in other cases the temperature remained unaltered

Results

In this first series, 50 injections were given to 43 patients, with the results shown in table I It appeared (1) that intravenous procaine injections, given as described, are effective in relieving the acute pain of chest-wall injuries and (2) that the pain of fractured ribs is relieved more fully than that of soft-tissue injuries This agrees with the findings of Batcher (1948)

TABLE I—FIRST SERIES 50 PROCAINE INJECTIONS IN 43 PATIENTS

—	Fractures (36 injections in 29 patients)	Soft-tissue injuries (14 injections in 14 patients)
No relief	8 %	44 %
Moderate relief	62 %	36 %
Great relief	30 %	20 %

TOXIC EFFECTS

None 44% Mild 54% Severe 2%

Second Series

It could be objected however that though the injections seemed to relieve most patients procaine was not necessarily responsible for the relief The patient, lying on a couch and receiving a protracted injection was under a strong hypnotic influence to which the benefit might be partly or entirely attributed A control series was therefore treated to ascertain how far the procaine was responsible

Two sets of 20 ml ampoules were prepared, identical and unmarked, one containing 1% procaine and the other containing physiological saline and these were placed in separate labelled boxes All injections were given by me but the ampoule I used was selected for me by a person with no knowledge of the case I recorded the effects of the injection without knowing the nature of the fluid injected, nor did I look at the key list (showing which ampoules had been used) until I had completed and analysed my observations.

In this series 53 injections were given to 40 patients, 32 receiving procaine and 21 physiological saline Results were again graded according to the measure of relief (table II) and adverse effects were noted. It is evident *that procaine injections gave far greater relief* Of the saline group 4 (19%) noted great relief—presumably being susceptible to the suggestive effect of the injection—and 11 (53%) were unaffected Of the procaine group 12 (36%) noted great relief, and only 5 (16%) were unaffected

TABLE II—SECOND SERIES: 53 PROCAINE OR SALINE INJECTIONS IN 40 PATIENTS

—	Saline (21 injections)	Procaine (32 injections)
No relief	53 %	16 %
Moderate relief	28 %	48 %
Great relief	19 %	36 %
TOXIC EFFECTS		
None	68 %	57 %
Mild	32 %	43 %
Severe	0 %	0 %

Of the 32 patients treated with procaine 2 lost consciousness for a few minutes, and 1 lost the power of speech and showed mental disorientation for ten minutes.

All 3 quickly returned to normal, and experienced continued relief of pain. In 2 of the procaine patients, both elderly men, the pulse became markedly irregular for about an hour, returning to normal without further cardiovascular disturbance neither had any obvious heart lesion

The patients treated with saline solution showed a lowing of the pulse similar to that seen with procaine, ut they did not show lowering of blood-pressure or ising of temperature.

The beneficial effect of the procaine was found to be greater in the second than in the first series The reason may be that the selection of cases with acute pain was stricter in the second series—i e, there was a higher proportion of the type of case most relieved by procaine Of the 32 procaine injections in the second series, 6 were second injections, now recognised as having less effect than the initial injections Procaine was again more effective in fractures than in soft-tissue injuries, whereas the relief given by saline solution was equally divided between the two

The second series establishes that procaine is the effective agent in the relief of pain Thus relief varies with

1 *Type of injury*—Fractures benefit more than soft-tissue injuries.

2 *Temperament*—The phlegmatic patient gains greater nd more prolonged relief than the sensitive

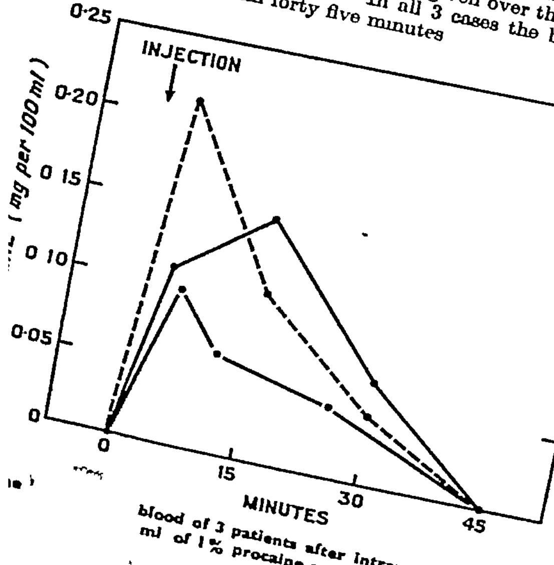
3 *Nature and degree of pain*—The more acute and generalised the pain, the greater the response

4 *Time-interval following injury*—The relief is greatest when injections are given within a few hours of injury With delay the pain seems to become "established" and the effect of procaine progressively less.

Suggested Mechanism of Pain Relief

The duration of relief afforded by intravenous procaine appeared surprisingly long Accordingly, procaine metabolism in the body was studied by estimating rocaine levels in blood and urine after injection The ollowing biochemical estimations were carried out by r R Gaddie, whose helpful advice was much appreated.

Blood procaine levels were measured in 3 patients, using a odification of Bratton and Marshall's method (Graubard et al 1947) Procaine in the serum rises to its peak within minutes of injecting (see figure), the injection given over the shortest time attains the highest level In all 3 cases the blood was free of procaine within forty five minutes



blood of 3 patients after intravenous injection ml of 1% procaine solution.

Urinary estimations were carried out in 3 cases amount of procaine excreted during the first hour was tively 7·7 mg, 1 1 mg, and 2·1 mg Excretion of after the first hour was negligible This confirms the of animal experiments showing that procaine is broken rapidly in the blood by procaine esterase, and by the liver the tissues (Lee 1947)

Thus procaine remains in the blood-stream than one hour, yet its effect may endure for days suggests that the relief of pain is due to abolition of vicious circle of pain→muscle spasm→pain, rather than to the purely local anæsthetic action.

Pulmonary complications such as collapse and monia are common following chest-wall injuries, larly in the elderly. As procaine given in the acute stage increases freedom of respiratory movement, its use should help to prevent these It should not, however, be given to elderly patients myocardial weakness, cardiac arrhythmia, or heart (Miller et al. 1952), or, of course, to patients known to sensitive to procaine

Summary

In a casualty department patients with chest injuries have been given intravenous injections of 1 procaine solution in the hope of reducing pain muscular spasm and thus improving respiration standard dose for a normal adult was 20 ml, in during not less than five minutes

Precautions are required against convulsions peripheral vascular failure, but these were not seen after any of the 82 procaine injections given. In 3 cases patient lost consciousness, and in 2 the power of was lost, but these effects were transient. In 2 men the pulse was irregular for an hour

Pain was greatly or moderately relieved in the large majority of the patients, and their respiratory and general condition improved The relief was greater in cases with fractures than in cases with only soft injury, and the benefit was greatest when the in was given soon after the injury In some cases the was immediate, in others it was delayed for a hours It lasted on the average for some twenty hours A second injection was never as effective the first.

Estimation of procaine levels in blood and urine an injection confirmed previous observations that procaine is excreted from the blood within an hour. Its effect over a period of hours or days is probably not due to any continuing anæsthetic action but to a breaking of the vicious circle pain→muscle spasm→pain.

In a small series of control cases, intravenous injections of physiological saline were given under exactly similar conditions Some benefit was evident, but it was much less than with procaine, and it was not greater with fractures than with soft-tissue injuries

I should like to thank Mr A. B Watson, director of the casualty department of the General Hospital, Birmingham, for suggesting that I should try intravenous procaine in these cases and for his great help and encouragement I am indebted to Mr R Gaddie, PH D, for the procaine estimations, and to Mr C McArdle and his staff for preparing the ampoules. The work could not have been completed without the help of my medical colleagues and the nursing staff in the casualty department

TWO CASES OF MYXŒDEMA ATTRIBUTED TO IODIDE ADMINISTRATION

M. E. Morgans
M.B. Lond., M.R.C.P.

W. R. Trotter*
D.M. Oxfd, M.R.C.P.

From the Medical Unit, University College Hospital Medical School, and the Elizabeth Garrett Anderson Hospital, London

The effect of iodide on the mammalian thyroid gland is curious and even paradoxical. When the quantity ingested is below a certain level (about 0·1 mg. daily in man) the gland cannot make adequate quantities of its hormone, and clinical hypothyroidism may develop. It has also been shown, both in the rat (Wolff and Chaikoff 1948) and in man (Stanley 1949, Childs et al. 1950) that single doses of iodide above a certain level (probably about 5 mg. in man) also prevent formation of the hormone, at least temporarily. This experimental observation may explain at least in part, the well known clinical fact that patients with thyrotoxicosis improve when given iodides. However, in such cases inhibition of the production of thyroid hormone is insufficiently complete or long lasting to produce clinical myxœdema (as it can be when drugs of the thiouracil series are administered), and in non-thyrotoxic subjects there is no recorded instance known to us of clinical hypothyroidism resulting from the administration of iodides.[1] We describe here two cases in which we believe that this happened.

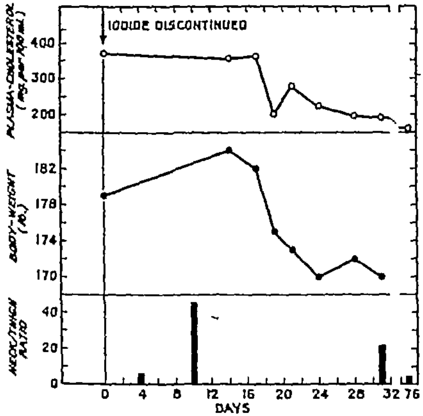

Fig. 1—Plasma-cholesterol, body-weight, and radio-iodine uptake in case 1 after iodide-containing cachets had been discontinued. Radio-iodine uptake was measured as the ratio of neck count to thigh count at two hours after administration of a tracer dose (normal range 1 to 10).

Case records

Case 1.—A man aged 66 underwent in 1945 resection of the colon for carcinoma. In 1950 he had been referred to the radiotherapy department of University College Hospital for treatment of a possible metastasis in the spine. During this treatment it was noticed that he was becoming slower, his face was becoming puffy, and his speech was indistinct. These changes were first noticed in January 1951. He was referred to Prof. M. L. Rosenheim, who diagnosed myxœdema and arranged for his admission to hospital.

On admission on June 29, 1951, the diagnosis of myxœdema was quite obvious. His face was pale and puffy, his skin dry, harsh, and cold, and his speech slurred. The thyroid was not palpable. The basal metabolic rate (B.M.R.) five days after admission was −15% and the plasma-cholesterol level 370 mg. per 100 ml.

Progress.—About a week after admission (no treatment having been given) it was noticed that he was becoming more alert and his face less puffy. Accordingly all treatment was withheld, and the signs of myxœdema gradually disappeared. Twenty-one days after admission the B.M.R. was −2% and the plasma-cholesterol level 200 mg. per 100 ml. (fig. 1).

Investigation.—The first radio-iodine study was done four days after admission. This was only a brief routine test and showed a neck/thigh ratio[2] of 6·5 at two hours after administration of a tracer dose of radio-iodine. This was well within the normal range of 1 to 10. More remarkable was the fact that the neck/thigh ratio at twenty-four hours after the administration of the radio-iodine was still 6·0. The significance of this observation was not appreciated at the time, but can only mean that all the radio-iodine in the thyroid must have been in the form of iodide. In other words, hormone formation must have been completely blocked at this time, as it would have been had the patient been taking large doses of thiouracil. Under these conditions a figure of 6·3 for the neck/thigh ratio indicates a fairly large thyroid iodide space such as is found in hyperplastic glands.

A second radio-iodine test was made six days later (ten days after admission). This gave a result totally different from that of the previous test. The neck count rose steeply, and two hours after the radio-iodine was given the neck/thigh ratio was 46·3. The peak uptake was at twenty-two hours and amounted to about 87% of the administered dose. The urine passed during the twenty-four hours contained only 5% of the dose. The neck counts were observed during the succeeding days. During the first four days they fell rapidly at a rate of 11% per day (euthyroid subjects usually have a rate of fall of 0–2% per day); then the rate diminished and ceased to be exponential. A sample of serum taken twenty-four hours after the radio-iodine was given contained 0·7% of the dose per litre, of which 90% was protein-bound. Thereafter the serum radioactivity increased rapidly, reaching a peak value of 2·9% per litre. Thigh counts, after an initial fall, rose in parallel (fig. 2). All these findings are what one would expect to find in well-marked thyrotoxicosis. The rise in serum and thigh counts in the days following the tracer

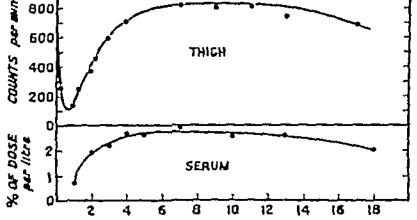

Fig. 2—Changes in counting-rate of neck and thigh regions, and of plasma aliquots, after a tracer dose of I¹³¹ administered ten days after discontinuation of iodide-containing cachets (case 1).

---

* In receipt of a grant from the Sir Halley Stewart Fund.

[1] Bell, cited by Werner (1953), appears to have encountered similar cases, but the text of his report to the American Goitre Association is not yet available in this country. Haben (1953) has recorded the development of myxœdema and goitre in a patient who had had a bronchogram. The inhibition of the thyroid was attributed to the absorption of iodide from the radio-opaque oil.

[2] Counting rates were measured with a Geiger counter 16·5 cm. from the neck, and another similar counter between the thighs.

dose [illegible] represents an outpouring of radioactive thyroid hormone into the blood

A third radio iodine test, done thirty one days after admission, gave a two hour neck/thigh ratio of 21 7 (still above normal limits) After this dose the neck counts fell at a normal rate (0 2% per day), and there was no secondary rise in thigh count

A fourth test done seventy-six days after admission gave a normal two hour neck/thigh ratio of 4 4.

It was apparent that at the time of admission the thyroid was being prevented from making its hormone by some unidentified agent This agent ceased to act soon after admission and the thyroid was then released and showed a very high turnover-rate Subsequently thyroid function gradually returned to normal This sequence of events would have been exactly reproduced if the patient had taken large doses of thiouracil continuously for many months up to the time of admission This would have caused hypersecretion of thyroid-stimulating hormone, with consequent hyperplasia of the thyroid If the thiouracil had been stopped at the time of admission, the thyroid would have been once more able to make hormone and, being hyperplastic, would have done so at an abnormally high rate As the level of circulating hormone rose, less and less thyroid-stimulating hormone would have been formed, and thyroid function would gradually have reverted to normal The patient was therefore closely questioned about any medicaments he had been taking The only one he had been taking constantly for long periods consisted of cachets for rheumatism, made up according to a formula given him by a previous private doctor

Powdered cinchona gr 3
Powdered guaiacum resin gr 6
Powdered ammonium carbonate gr 2
Powdered lithium carbonate gr 2
Potassium iodide gr 1
Powdered colchicum gr ¹/₈

The dose was one cachet t d s He had started taking this before the war and, apart from two years during the war (when he was unable to obtain it), had continued to do so regularly and continuously up to the time of admission. He took none while in hospital

A review of the constituents showed that none (apart from the potassium iodide) were known to have any anti thyroid action This was confirmed as follows

Experiment—100 mg of the mixed powder (but excluding the potassium iodide) was suspended in water and given to each of five rats (each weighing about 100 g) by stomach tube This dose amounted to slightly less than the patient's usual daily dose, or about 700 times his daily dose on a body weight basis An hour later these five rats, and five control rats, were each given 5 μC of I^{131} intraperitoneally They were killed three hours later, and their thyroids were digested in 10% sodium hydroxide and counted in a liquid counter In both treated and control rats the mean thyroid content of radioactivity amounted to 34% of the administered radio iodine The patient's daily dose of potassium iodide was 180 mg (136 mg of iodide)

Follow up—After the patient left hospital he started taking the cachets once more in the same dose After nine months his weight increased by 13 lb and his plasma cholesterol level rose from 160 to 240 mg per 100 ml There were no obvious signs of myxœdema He then discontinued the cachets, and a week later a radio iodine test gave a two hour neck/thigh ratio of 27 0 Thirty three days after the cachets had been discontinued this had reverted to a normal level of 7 8 These observations suggested that his thyroid had once more become hyperplastic while he was aking the cachets and that this had enabled it to produce nough hormone to prevent gross myxœdema

At about this time the patient developed progressive undice which ended in his death a year later

Necropsy Findings—Deposits of secondary carcinoma were und in the abdominal lymph glands and the liver was ssly cirrhotic The thyroid was diffusely enlarged, weighing g examination showed a very uniform large acini distended with colloid and lined There was no lymphocytic infiltration.

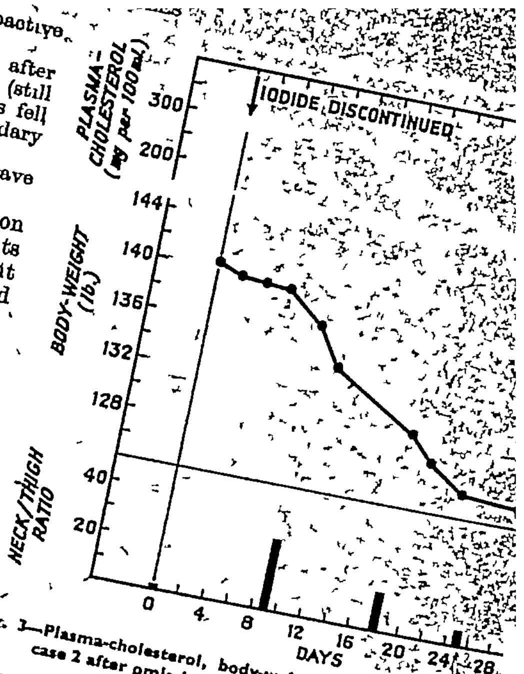

Fig. 3—Plasma-cholesterol, body-weight and radio-iodine up
case 2 after omission of iodides from an asthma mixture

Case 2.—A housewife, aged 45, was admitted t Elizabeth Garrett Anderson Hospital, complaining backache and a gain of one stone in weight in three four months She had noticed swelling of her abdom face, and hands for six weeks, and that she tired a felt the cold more easily than before Her voice become husky over the last few weeks She known asthmatic, and it later transpired that she been in the habit of taking a mixture containing gr of sodium iodide[3] (423 mg of iodide) at least four h and sometimes more often over the last four years

On examination she was pale and lethargic, with much puffiness round the eyes and œdema of both legs, reaching the knees and pitting with difficulty The skin was and cold. There were occasional rhonchi in the lungs The thyroid gland was easily seen and felt, it was enlarged and extremely firm on palpation, it was abnormally vascular and moved easily on swallowing

A clinical diagnosis of myxœdema was made, associated with a Hashimoto thyroiditis, because of the firm enlargement of the gland

Investigations on admission supported the diagnosis, the B M.R being −21% and the plasma-cholesterol level 300 mg per 100 ml Radiography of the chest showed a heart shape compatible with myxœdema.

Treatment and Progress—As the ingestion of large dos of iodide was a common factor in both cases 1 and 2, it w decided to omit the iodide from this patient's medicines, a other constituents remaining the same This was followed by a dramatic change in the clinical state over the ensuing three or four weeks The œdema and puffiness disappeared the body weight falling from 140 to 126 lb, with a diuresis maximal on the sixth day after withdrawal of the iodide The patient became more alert, her skin finer and warmer and her thyroid gland very much smaller and softer, with the result that at the end of this time it was difficult to feel The plasma-cholesterol level fell from 300 mg per 100 ml to 150 mg per 100 ml (fig 3) Unfortunately a final B.M. reading was unobtainable because the patient went into status asthmaticus on withdrawal of the iodide Radiography of the chest showed considerable reduction in the heart at the end of the period (fig 4)

Radio iodine measurements made before withdrawal of the iodide and at intervals afterwards as in case 1, were follows

	Neck/thigh ratio	*Dose of radio-iodine in thyroid at 24 h*
Before withdrawal	0 75	1 7
9 days after withdrawal	27-30	79
18	15 95	63
25	7 50	[illegible]

---

[3] Potassium bromide gr 5 Liquid extract of liquorice minims 1 Chloroform emulsion minims 7 Caffeine iodid

These results showed a similar trend to case 1. There was a practically zero uptake at two and twenty-four hours on the day following withdrawal of the iodide. Nine days later these measurements were in the thyrotoxic range, suggesting a hyperplastic thyroid gland. Eighteen days after withdrawal of iodide the levels had fallen, but they were not within the normal range until twenty-five days. At the end of this time the patient was in a severe status asthmaticus and for psychological reasons we were forced to administer iodide again in the exact mixture as before. Within a week the thyroid gland became easily palpable and very firm.

It therefore seemed that in this case also the iodide had an anti-thyroid action, causing blockage of formation of thyroxine and consequent hyperplasia of the gland and myxœdema.

The patient has now been discharged taking her medicine. She will be given thyroxine if evidence of myxœdema appears; for it seems unlikely that she will be willing to give up her iodide mixture.

Discussion

In case 1 the signs of myxœdema disappeared shortly after the patient was admitted to hospital although no treatment had been given. Four days after admission his thyroid gland could concentrate iodide but not make hormone. Six days later radio-iodine studies showed that iodine was passing through the thyroid and emerging in the blood in protein-bound form at an abnormally high rate—in fact at a rate commonly found in thyrotoxicosis. Some weeks later, when all signs of myxœdema had disappeared, the radio-iodine uptake gradually returned to normal. These studies strongly suggest that thyroid function had been severely depressed and then suddenly released, with a period of rebound overactivity. Thyroid function was released from four to ten days after admission to hospital. Since the patient's diet at home did not differ much from the hospital diet, the most likely reason for the release of the block to the thyroid on coming into hospital was that he had ceased to take his cachets from the time of admission. It might still have required from four to ten days to reduce his blood iodide to a level at which it would not affect thyroid function. Further evidence that the cachets were responsible was obtained from the temporary increase in radio-iodine uptake seven days after the end of a second course of cachets. The constituents of the cachets, other than potassium iodide, were shown to have no anti-thyroid action in rats. The evidence therefore pointed to iodide as the cause of his myxœdema.

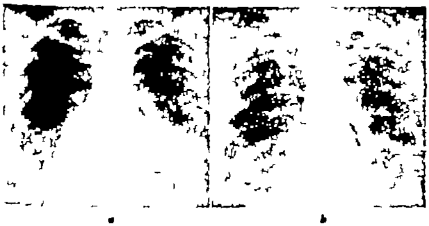

Fig. 4—Size of heart in case 2: *a*, while the patient was taking iodide-containing mixture; *b*, 14 days after omission of iodides from the mixture.

In case 2 the removal of the iodide from the asthma mixture without any other change, led to the same sequence of events. The signs of myxœdema disappeared, and the uptake of radio-iodine which had been nil became supernormal and then gradually returned to a normal value, suggesting a phase of rebound overactivity as thyroid function was released. Since the potassium iodide was only discontinued after a period of observation in hospital and was the only constituent removed from the asthma mixture it seems highly probable that it was the agent responsible for suppressing thyroid function.

In case 2 a moderate-sized firm goitre had been present when she was myxœdematous. After the iodide was discontinued, the goitre rapidly became smaller and softer. When iodide was restarted the goitre again became more obvious. The presence of the goitre is interpreted as an attempt to overcome the difficulty in making thyroid hormone.

In view of the experimental observations of Wolff and Chaikoff (1948) and Stanley (1949) it is perhaps surprising that no other instances of myxœdema attributable to iodides appear to have been recorded. One reason, no doubt, is that a diagnosis of myxœdema is usually followed automatically by the administration of thyroid extract, without a search being made for a possible causal agent. Even if an allowance is made for this, it seems certain that other cases would have been recognised if the exhibition of iodides commonly caused myxœdema. It seems much more likely that the human thyroid becomes in some way tolerant to high blood-iodide levels, as is suggested by the work of Wolff et al. (1949) in rats. They showed that when high blood-iodide levels were maintained the thyroid's capacity for binding iodine returned during the course of a few days. This experimental observation is not necessarily relevant to the state of patients who are taking iodides, since their dosage is unlikely to be as regular and as evenly spaced throughout the twenty-four hours as that of the rats. A fall of the blood-iodide level below the critical level for blocking organic binding might have effects in opposite directions according to the interval between doses. On the one hand intermittent dosage might prevent the development of tolerance to iodide. On the other hand, if the intermissions were long enough, the thyroid might be able to produce enough hormone intermittently to prevent myxœdema. The fact that both our patients had been taking iodides for several years before myxœdema appeared, and that case 1 did not develop gross myxœdema within nine months of resuming iodides, suggests that the formation of thyroid hormone was not continuously suppressed in either patient.

Keating et al. (1950) found normal values for radio-iodine uptake in 21 euthyroid persons about a week after discontinuing heavy doses of iodides. It can therefore be presumed that their thyroids had not become hyperplastic. In most instances the normal thyroid can apparently evade the blocking action of iodides. Our two patients seem to be peculiar in that their thyroids could not do so.

Summary

In two patients with myxœdema the symptoms and signs disappeared on discontinuing iodide-containing medicaments which they had been taking for many years. In one case a goitre was present, and this became much smaller.

Radio-iodine uptake, measured nine and ten days after discontinuing iodide, was in the thyrotoxic range in both cases. A few weeks later it had returned to normal in both cases.

The myxœdema is ascribed to the anti-thyroid action of iodides.

ALOPECIA, OPTIC ATROPHY, AND PERIPHERAL NEURITIS OF PROBABLY TOXIC ORIGIN

W J C SYMONDS
B M. Oxfd

JUNIOR MEDICAL REGISTRAR, GUY'S HOSPITAL, LONDON

THE association of alopecia, optic atrophy, and peripheral neuritis in the same patient is in itself remarkable, and, in the light of recent additions to our knowledge of the ætiology of the peripheral neuropathies (Elkington 1952), suggests a selective biochemical disorder In the present case the illness began acutely with vomiting and diarrhœa, and the occurrence of these symptoms at the same time in other members of the household, followed in one case by alopecia, is evidence of a common toxic cause.

Case-record

A housewife, aged 59, was admitted to Guy's Hospital in September, 1950, with loss of vision, loss of hair, and pains in her legs She was a trained nurse and a doctor's widow She had been liable to attacks of depression since 1943, when she was living alone in the Midlands, and in October, 1948, had attempted to commit suicide by taking morphine. In June, 1949, she moved into a flat at the top of her son in law's house in Surrey

Beginning of Illness

Her illness began in July, 1949 On the 15th there was a family reunion luncheon in the patient's flat, attended by her son, her married daughter, and her son in law (who are all doctors) and their child. About twelve hours later the patient began to vomit, with some diarrhœa and abdominal colic. These symptoms continued for two days and were followed by nausea and anorexia for a week. At about this time, and during the next two weeks, the hair of her scalp and eyebrows fell out progressively until she was completely bald On July 31 she developed tingling and shooting pains in her feet, hands, and scalp, these became worse until she could neither walk nor sleep

Son's Illness

About forty eight hours after the luncheon on July 15 her son developed general lassitude and aching in his legs About a week later most of his scalp hair fell out and it took about three months to grow again. At the same time his sister, her husband, and their child had vomiting and diarrhœa for about two weeks

First Investigation and Treatment

On Sept 5, 1949, the patient was admitted to another hospital after an exacerbation of vomiting She had complete alopecia of the scalp and eyebrows and hyperæsthesia of the toes and her leg reflexes were sluggish. A blood count showed severe polymorph leucocytosis but no anæmia. The blood-urea and blood sugar levels were normal, and lumbar puncture produced normal cerebrospinal fluid under normal pressure

Thallium poisoning was diagnosed, although examination of the urine and fæces and muscle biopsy revealed no trace of this metal The patient was given a course of dimercaprol in the dosage recommended by the Medical Research Council (1947) The pains began to regress during the following few days but at the same time her vision started to deteriorate rapidly being reduced in about two weeks to 6/60 in each eye After another two weeks her visual acuity began to improve, and her hair to grow again, but unfortunately she became increasingly depressed and had to be removed to a mental hospital for a while, after which she seemed restored to a reasonably happy state of mind

Maid's Illness

She returned home in December, 1949 In January, 1950, a maid working in the patient's flat had a short attack of diarrhœa and vomiting followed by loss of hair

Patient's Relapse

The patient continued to improve, and by March, 1950, she could read large print examination of her fundi at this time showed slight optic atrophy In July, 1950, however, her vision rapidly deteriorated again, and about two weeks later her hair began to fall out and she developed severe paræsthesiæ in the lower legs, scalp, and abdomen.

Further …

On … to Guy's Hospital on Sept 12 1950, she was … bald Her eyebrows were also affected, but not her pubic or axillary hair Her vision was so poor she could not identify a hand if it was held more than … away from her eyes, and the fundi showed bilateral … atrophy There was slight hyperæsthesia of both calves … deep pressure, and possibly some reduction of vibration … in the feet. She was naturally anxious about the loss … vision but otherwise did not seem to be unduly depressed … blood-count showed slight polymorphonuclear … A test-meal showed normal gastric acidity and emptying, … blood urea and serum protein levels were normal

Further Treatment

Again, a clinical diagnosis of thallium … although no trace of this metal was found in samples of … nails, and urine However, the patient had impa… tolerance, which seemed to support a diagnosis of heavy … intoxication (Joiner et al 1950) Accordingly she … another course of dimercaprol in higher dosage than … (4 ml of a 5% solution intramuscularly q d.s. for four … then 4 ml. t d.s. for four days, and then 1 ml daily for … days) After five days' treatment pyruvate tolerance … normal, but no heavy metal was detected in the urine … this period, in spite of repeated attempts The … paræsthesiæ gradually disappeared during the treatment … her hair started to grow again. Her vision improved slight… and when she was discharged on Nov 20, 1950, her … acuity was 1/60 Since then, however, there has been … progress.

Search for a Poison

Careful search was made at the patient's home, b… the incident in July, 1949, and again in 1950, but … known to contain thallium (or other heavy metal) wa… After the first incident all the patient's culinary … utensils were changed, and the water in the house's … tanks was analysed with a negative result.

Discussion

From this lady's story, and the fact that other … of the household were affected, it seems reasonab… assume that this was a case of recurrent poisoning … are very few substances which will cause alopecia, … alone one as complete as this. Alopecia areata … may occur in members of the same family, and … quite rapid in its onset, but it would be a … coincidence for it to happen in two members at the … time When optic atrophy, peripheral neuritis, and … of diarrhœa and vomiting are added to the syndrome, … seems difficult to imagine as the cause any substance … than thallium salts. It is true that arsenic will … of hair as well as paræsthesiæ, blindness, and … intestinal disturbance, but it does so more gradually … effects being patchy and not so dramatic as in the … case

USES AND EFFECTS OF THALLIUM

Thallium is not in common use Commercially it … employed in a rat poison and an insecticide, and … year 1930 a depilatory cream was marketed in the U.S.A. … which caused numerous cases of poisoning (American … Medical Association 1931) and manufacture of which was … abandoned in 1932 Industrially, the liberation of … thallium in the manufacture of sulphuric acid from iron … pyrites has been reported as causing toxic effects (Buschke … and Langer 1927) It is used also in making filaments in … tungsten lamps, in some imitation gems, and in low … temperature thermometers Its therapeutic use has been … abandoned almost completely.

Thallium's toxic effects were noted very soon after its … discovery Lamy in 1862 developed peripheral neuritis … while working with the metal, which he had identified … independently of Crookes, who made his discovery the … year before (Lamy 1863a, Crookes 1861), and found that … it was lethal to animals (Lamy 1863b)

Alopecia

Combemale (1898) found that thallium caused alopecia in … patients to whom he administered it to alleviate night sweats … and at about the same time Sabouraud noted the same effect … in a person who had been given thallium to control diarrhœa … This led him to use the acetate salt locally and orally for the … treatment of ringworm of the scalp, but because of its toxicity … he soon abandoned its use in favour of X irradiation, and … advised that thallium acetate should only be …

peutically in strengths of less than 1%, and then in only small doses and at long intervals (Sabouraud 1912)

Ocular Symptoms

Kaps (1927) first noted optic atrophy in a human case of acute thallium poisoning (which in his case was preceded by retrobulbar neuritis) and since then further cases have been reported (Girot and Braun 1929 Lillie and Parker 1932) Non inflammatory keratitis (Richet 1899) and cataract (Duke Elder 1947 Castelao 1941) have also been reported.

Mental Disturbances

Mental symptoms during the acute phase have been described varying from delusions of persecution (Bachkevitch and Prokoptchouk 1929) to depression and suicidal tendencies (Greving and Gagel 1928) or even complete dementia (Kaps 1927). This might explain our patient's depression during the first episode in 1940 but she seems to have had such a tendency for long before then

Alimentary Tract

Ulcerative stomatitis with blue line albuminuria and tachycardia have also been reported (Ginsberg and Nixon 1932) and experimentally thallium seems to promote the flow of impulses in the autonomic nervous system (Dixon 1927) Diarrhœa and vomiting with abdominal colic, are typical of the acute poisoning and the fact that there was some delay between the appearance of these symptoms and the probable ingestion in the present case supports the diagnosis. Indeed it seems probable that these effects develop only after the thallium has been absorbed (Dixon 1927) because similar symptoms appear after local applications.

Blood Picture

The leucocytosis which was present during both of our patient's attacks are also consistent with thallium poisoning and on occasion thallium seems to cause anæmia also (Mamoli 1936, as a result of experiments on albino rats)

Endocrine Glands

There has been much discussion as to whether thallium has specific toxic effects on the endocrine glands, but Cox and Hodgerson (1936) have made investigations which tend to disprove this

Unfortunately we could not detect thallium in abnormal quantity in the present case but this fact certainly does not exclude the diagnosis of thallium poisoning because we could not investigate the patient at the immediate onset of the symptoms of her episodes. (The methods used for examination of specimens were spark spectroscopy and a polarographic method devised by Mr R. W R Baker) The impaired pyruvate tolerance test during the second episode in 1950 was suggestive of poisoning by a heavy metal especially as it returned to normal after treatment with *dimercaprol* (*Joiner et al.* 1950) It is difficult however to ignore the facts (1) that we could find no history of contact with thallium or any heavy metal and (2) that thallium is not in common use.

SIMILAR CASES

Euzière et al (1951) have reported three cases of recurrent polyneuritis with alopecia closely resembling that described here. These three patients were men separately observed, and without any association with one another who developed recurrent bouts of alopecia together with symptoms and signs of polyneuritis Two of them also had optic atrophy with almost complete loss of vision, and one had irritability and depression with suicidal tendencies Euzière et al considered the possibility of thallium poisoning but there was no evidence of contact with thallium, and they do not appear to have searched for it in the patients excreta.

Stiefler (1929) reported two cases of unknown ætiology with paræsthesiæ and alopecia of acute onset, associated also with painful and swollen joints. Radermeker (1944) describes two patients who suddenly developed paræsthesiæ and alopecia, one also showing optic atrophy Both patients had paralysis of the lower limbs and sphincters, isolated cranial nerve palsies, and an increased amount of albumin in the cerebrospinal fluid In none of these four cases were the attacks recurrent.

Bingel (1931) described the case of a married woman who had recurrent attacks of alopecia and of paræsthesiæ in her legs and died in the third bout Each recurrence took place when the patient returned home from hospital and owing to this and her husband's rapid remarriage after her death a necropsy was performed in which a careful search was made for thallium and arsenic, but without success. Bingel considered his case to belong to the same group as those described by Stiefler (1929) but the published case reports do not support this conclusion

In the present case the circumstantial evidence of poisoning seems reasonably strong, but the only reason why thallium has been advanced as a possible cause is that it seems to be the only substance which could give rise to this syndrome The strongest argument against this diagnosis is the failure to find any history of contact It may well be that this case (and possibly those of Euzière et al and that of Bingel) were due to some hitherto unsuspected toxic cause

Summary

The case is reported of a patient with recurrent bouts of alopecia, optic atrophy and peripheral neuritis

A comparable illness affecting at the same time other members of the household suggests a toxic cause.

The evidence for and against the diagnosis of thallium poisoning is discussed

The conclusion is reached that the syndrome may result either from thallium poisoning or from some other toxic cause at present unidentified

INFANTS' LEGS AND THE SLEEPING POSITION

M. Pickering Pick
M.B Lond., F.R C.S

CHIEF ASSISTANT ORTHOPÆDIC DEPARTMENT ST THOMAS'S HOSPITAL, LONDON

During the latter part of pregnancy the fœtus occupies very cramped quarters in the uterus and therefore adopts a position in which it occupies the least possible volume As part of this attitude the legs are folded one upon the other the hips are fully flexed and externally rotated the knees are flexed the tibiæ are crossed one over the other and each foot is pressed on to the opposite buttock (fig 1) To maintain this position certain adaptive changes are made, and can be observed if the legs of a newborn child are examined

The *feet* lie on the buttocks, and are moulded to their surface The heels are in slight varus and the fore feet are inverted and adducted

The *tibiæ* lie crossed one over the other with the result that they are bowed laterally The bow is most marked in the

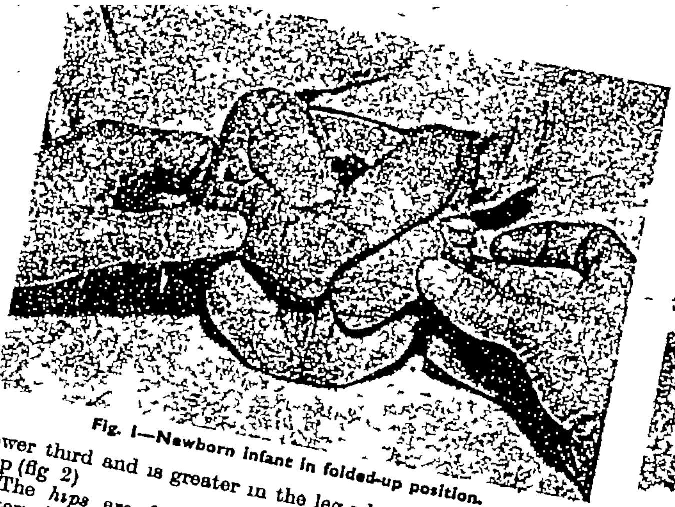

Fig. 1—Newborn infant in folded-up position.

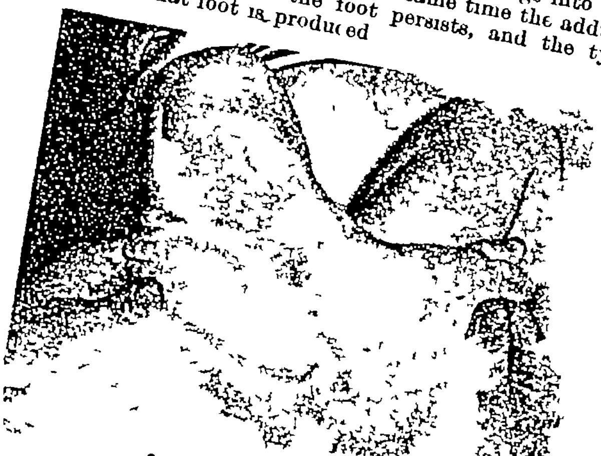
lower third and is greater in the leg which habitually lies on top (fig 2)

The *hips* are fully flexed and externally rotated Full external rotation of the hip in the young infant is, however, diminished and internal rotation is correspondingly greater than normal This altered arc of rotation is caused by an increase in the angle of anteversion of the neck of the femur on the shaft, which is present in the newborn and decreases with age (Dunlap et al. 1953) The effect is that, in full lexion and external rotation, the knees cannot fall sideways outside the line of the trunk as they would in an older child, and thus the child's volume is not increased

Many small children habitually adopt the "folded up" position during sleep, at the same time lying prone with the buttocks raised (fig 3) If this habit persists, the adaptive attitude of the legs remains, and, if the child is still sleeping in this position when it starts to walk, certain errors of stance and gait are noticeable Such a child walks with flat feet, bowed tibiæ, and an intoe gait

Infantile Flat foot

This is almost universal in the toddler Two factors are responsible The first is general, and consists of an inability to balance on the subtaloid joint, with the result that the foot collapses into valgus in exactly the ame position that a person adopts when learning to kate on ice The second is due to the fact that in the folded up position the fore part of each foot is inverted and adducted When the child places the fore part of the foot flat on the floor, the heel swings into valgus and the arch collapses At the same time the adduction of the fore part of the foot persists, and the typical infantile flat foot is produced



2 years, showing the ease with which the legs can be folded up.

Fig 2—Same infant as in fig 1, showing bowed tibiæ

Infantile Bowed Tibiæ

As has been pointed out, this is a lateral bow marked in the lower third These children are healthy and often overweight They bear none stigmata of rickets; so the common suggestion is a rickety deformity is obviously untenable

Infantile Pigeon Toes

The intoe gait of young infants has been an internal rotation deformity in the tibiæ adduction of the fore parts of the feet Th these factors may contribute, examination of of such a child will show that most of the arises at these joints

Fig 4 shows that there are increased internal and decreased external rotation at the hip This arc of rotation is due to an increase in anteversion neck of the femur, which may be as much as 80° newborn and diminishes with age The mid of rotation is on the internal side of the arc,

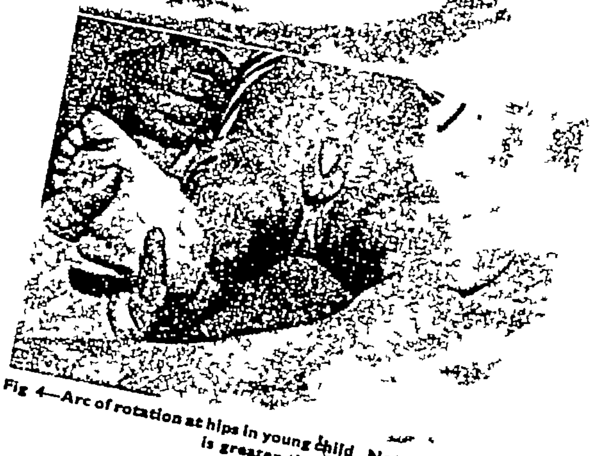


Fig 4—Arc of rotation at hips in young child Note that internal is greater than external

is that such a walks with its , internally at the hip 5)

CONCLUSION

ough most prac oners recognise there is a spon ous tendency to of these se so called rmities during I hope they find this simple useful in worried s, and that it render unneces the use of two expensive shoes—wedged and remedial cases. The simple vre of testing ion of the hips folding the legs the sleeping posi quickly reveals reason for this n cause of parental concern

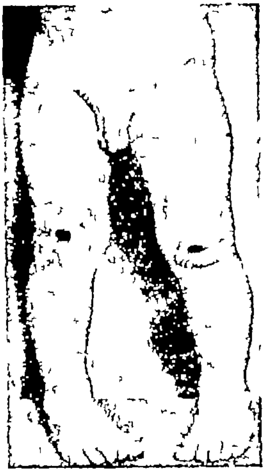

Fig. 5—Same child as in fig. 4 standing with varus feet, bowed tibiæ and inversion of hips.

wish to thank Mr K. G Moreman of the photographic of St Thomas's Hospital, for the photographs

MYCETOMA OF THE TESTIS

P R R CLARKE
M.B Lond, F.R.C.S

LATE SURGICAL SPECIALIST MINISTRY OF HEALTH SUDAN GOVERNMENT

TOMA or maduromycosis is a fungus disease of distribution found most frequently in warm tries It is prevalent in many districts of India ularly round Madras) in Indonesia in South and in many parts of Africa Cases have also reported from Greece and Italy and from the States of America (Peters 1945)

on of a piece of tissue affected by this fungus destruction of anatomical structures and the nce of multiple cavities containing coloured granules, y black or yellow but sometimes red or white is generally accepted that the fungus is introduced wound, and in many cases a piece of thorn can be d in the affected tissue According to Strong (1944) ore than 70% of cases the foot is the part affected, hands, knees, and buttocks may be involved and Kirk (1940) reported a case of mycetoma he eyelid and de Almeida and Abdalla (1939) have hed 11 cases of thoracic mycetoma

Wad Medani hospital which has 300 beds and is principal *hospital in the Gezira irrigated area lying* the Blue and White Niles, 115 cases came to in the sixteen months from August, 1951, to mber, 1952. The parts of the body affected were

Part of body	*No. of cases*
Foot and leg	96
Hand	13
Elbow	1
Scalp	3
Buttock	1
Testis	1

There were 79 cases of black mycetoma, 35 of yellow, and 1 of red

A male Sudanese aged 35 was admitted to hospital on July 13 1952, with a month's history of a painless swelling of the left testicle. He had undergone an operation for hydrocele on the left side ten years previously

On examination there was a smooth enlargement of the body of the testis as large as a cricket ball There was no thickening of the cord Rectal examination revealed no abnormality and there were no abdominal tumours to be felt. The skin over the outer aspect of the scrotum was adherent to the underlying structures but there was no sinus. There was no sign of hydrocele Testicular sensation was considerably impaired. Wassermann and Kahn tests were not done.

Operation.—On July 15, 1952, the left testicle the overlying skin and the cord and vas up to the internal ring were removed in one piece

Pathology.—Section of the testicle showed that only a very small portion of normal testis remained The rest of the enlarged organ was occupied by numerous cavities stuffed with coarse black granules of mycetoma, each granule being as large as a pin's head

Recovery was uneventful

No history of trauma was obtained in this case and it is unlikely that an operation for hydrocele ten years previously had any bearing on the development of mycetoma in this unusual situation. Nevertheless it is probable that minor injury from a small thorn or similar object introduced the fungus

My thanks are due to Dr C B Drew director of medical services, Ministry of Health Sudan Government for permission to publish

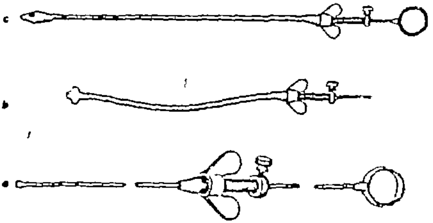
New Inventions

NEW INTRODUCER FOR THE SELF-RETAINING CATHETER

THE safe introduction of a self retaining rubber catheter of the de Pezzer or Malecot pattern depends on the fact that its expanded tip is stretched out by a metal introducer passed up its lumen. Experience has shown that the end of the metal rod sometimes perforates the tip of the catheter when the latter is being extended by it or during the introduction of the catheter Further, there is often some difficulty in keeping the catheter stretched upon the metal introducer This new instrument has been designed by Mr Joseph Atkinson, male charge nurse in the main theatre here, with a view to overcoming these difficulties.

The illustrations, drawn by our surgical artist Mr D P Hammersley show how this instrument works. It consists of two pieces (see *a* in figure) a metal rod with a small bulbous tip and a ring handle at the other end and a short length of metal tubing which forms the fixed base through which the rod slides. The catheter is fixed to the base by pushing its proximal end over a



onical cuff with a deep shoulder and by tightening a winged screw down upon the end of the catheter (see *b* in figure) Thus held securely the catheter is extended by pushing the metal rod forward to the required extent (see *c* in figure) The rod is next fixed to the base by tightening the thumbscrew down upon it

This instrument is being made in two sizes for larger and smaller catheters, and Messrs Chas Thackray & Sons of Park Street, Leeds, will produce it

Reviews of Books

The British Contribution to Medicine

JAIME JARAMILLO ARANGO, former rector of the National Faculty of Medicine of Bogota Edinburgh E & S Livingstone 1953 Pp 220 25s

THE author was an eminent surgeon in Colombia before he became first minister and then ambassador of that republic in London, a position he held for many years, including those of the second world war This impressive, well-illustrated book is conceived as a permanent memorial of his mission Sir Arthur MacNalty, in a foreword, tells us that it was first written in the pure Castilian prose of which the author is so complete a master It is primarily designed for the use of doctors and students in the Latin-American countries, and the English edition has been prepared concurrently

A general historical survey of British contributions to medicine is followed by a detailed study of five special subjects in which British investigators have illuminated knowledge Sir Almroth Wright's pioneer work on antityphoid inoculation, the story of the discovery of penicillin the conquest of malaria, including the synthesis of paludrine the conquest of nutritional disease, and the struggle to find a cure for cancer, including the pioneer work on stilbœstrol and other similar products with œstrogen action Dr Jaramillo Arango very properly strays at times beyond the scope of his title, and includes, out of interest an account of the history of the antibiotics other than penicillin in which few British names appear

Much of the text is written with charm and distinction, and though occasionally the story becomes complex, it cannot fail to leave a glow of national pride in the British readers, the more so because it is the appraisal of a competent foreign critic who has lived among us

Mushrooms and Toadstools

A Study of the Activities of Fungi JOHN RAMSBOTTOM London Collins 1953 Pp 306 30s

Mr Ramsbottom, D SC, who recently retired after forty years' service in the department of botany at the British Museum (Natural History), here contributes a volume to Collins's New Naturalist series, it is therefore not a textbook for use in the identification of fungi but a general account of different aspects of mycology, including history, mythology, uses, and ecology The excellent and numerous illustrations are mostly from colour photographs by Mr Paul de Laszlo, but also include nine photographs by Mr Somerville Hastings, F R C S, an aerial view of Stonehenge (to show fairy rings") by Mr O G S Crawford, and a view of the fermenting plant of Glaxo Laboratories

The chapters of greatest importance to medical readers are those dealing with poisonous and edible species, ergot, and penicillin, the last named is one of the best short accounts of this discovery hitherto published The poisonous fungus most likely to be met with in this country is undoubtedly the death cap (*Amanita phalloides*) so details are given of the identification of this species the symptoms and treatment of poisoning by it and the history of the analysis of its toxins Over a hundred years ago J Roques recommended a large quantity of either honeyed or sugared water as an antidote, and in 1936 Le Calvé[1] gave salt by mouth and by injection The former combats the hypoglycæmia and the latter the dehydration caused by the toxins An ingenious remedy—the stomachs of three rabbits and the brains of seven (both magic numbers) chopped up and administered raw in is based on the fact that rabbits are insusceptible to po by death cap eaten in small quantities and on the assu that there are two toxins, one acting on the brain and other on the liver Alleged cures might have been Dr Ramsbottom suggests, to the sugar in the jam more modern method of giving methionine to combat to the liver, and glucose to combat the hypoglycæmia not mentioned

Extrasystoles and Allied Arrhythmias

DAVID SCHERF, M.D, F.A C.P, associate profes medicine, New York Medical College, ADOLF S M D Heidelberg, M R C S, medical officer in charge of cardiographic department, Queen Mary's Hospit the East End, London London Heinemann M Books 1953 Pp 531 £5 5s

THIS Anglo-American combination of authors an exhaustive account of a subject which they have studying for many years The forms of irregular, were not properly classified until the beginning of century, before then their significance was not unde and bed was often prescribed for physiological arrhythmia Even today slow fibrillation can be m for extrasystoles and auricular flutter for sinus t cardia Less attention has been paid recently to n heart rhythms, though their diagnosis and tre are matters which confront the practitioner Professor Scherf and Dr Schott, in their opening ch on the history of their subject, show how irreg the pulse impressed the older medical writers and extensive information they thought they could from it They discuss extrasystoles first from the standpoint—considering the various sites of the known causes, their relationships with other orders of rhythm, and their many physiological, pathological associations They go on to cor explanations of the mechanism both of the extrasystole and the rarer parasystole They that the common extrasystole most probably orig in an abnormal focus activated by the normal parasystoles, they think, are produced by an aut regularly discharging focus protected by a zone of The book has some of the oddness of expression to expected of authors not writing in their native lang Though there is no actual padding in the text, th a good deal of repetition This is mainly an acc work but one that cardiologists will find useful.

Antibiotics and Children's Diseases

Seminar Organised in Paris, Sept 22–27, 1952, by International Children's Centre Chairman ALEXANDER FLEMING Paris Centre Intern l Enfance London Lange, Maxwell & Springer Pp 298 £3 3s

THIS is an account of the proceedings of a semin last September at the International Children's C Paris, under the presidency of Sir Alexander F Both clinical and laboratory aspects are discusse the section on tuberculosis is especially full Whi book contains little that has not already been p elsewhere, it is useful to have so much up to-date inf tion on the subject collected together in one volum

---

Operative Gynæcology (2nd ed London 1953 Pp 902 £6)—Six years have elapsed since publication of the first edition of Prof Richard W Te book, and, as he points out, in this period not only the expected evolutionary changes in surgery taken but views have altered on such things as the uses of therapy and antibiotics, the assessment of the vaginal technique in the diagnosis of cancer, and other matt considerable importance Like its predecessor this ed informative without being verbose indeed in places almost condensed The teaching is commendably but opposite or different policies are given fair consid Professor Te Linde is so clear in his own mind about best for the patient that he is able to be dogmatic [illegible] more is given than pure operative technique he includes [illegible] necessary the fundamentals of obstetrics, and related asp of urology endocrinology, and above all pathology The bo which is profusely and beautifully illustrated, is already m valued by gynæcologists, and the new edition is welcome

An advance in oral iron therapy

Clinical trials have shown that Anorvit, the new B D H preparation of iron with vitamins C and K, provides most effective absorption of iron with remarkable freedom from gastro-intestinal disturbance

'ANORVIT' TABLETS

Containing ferrous sulphate, exsiccated, 3 grains (200 mg approx) ascorbic acid 10 mg and acetomenaphthone 2 mg

DOSAGE

Children—1 tablet 2 or 3 times a day Adults—2 tablets 3 times a day

Basic N.H.S. prices Bottles of 50 tablets 1/10 and 500 tablets 9/6

Detailed literature and specimen packings are available on request

MEDICAL DEPARTMENT

THE BRITISH DRUG HOUSES LTD LONDON N 1

ANR/E/31

NEW— Nasal spray with NEOPHRYN

This powerful but non irritant decongestant is now available as a spray to provide symptomatic relief whenever nasal congestion occurs. The new spray can easily be carried in the pocket or handbag, and has been precision engineered with a micro-jet tip to give an adequate dose of 'Neophryn in a fine even spray

NEOPHRYN

Trade mark

Basic N H.S cost 2/4d.

Manufactured in England by BAYER PRODUCTS LTD, Africa House, Kingsway London, W.C.2

Associated export company : WINTHROP PRODUCTS LIMITED LONDON

Adequate Cough Sedation permits

QUIET, UNINTERRUPTED SLEEP

In the treatment of unproductive cough in children and adults the advantages of ETHNINE lie in its effectiveness with low toxicity, and its freedom from side-effects such as constipation and digestive upset

For children, ETHNINE is indicated whenever a cough sedative is considered advisable particularly in the treatment of whooping cough, irritation of the upper respiratory tract, and the cough associated with enlarged tonsils and adenoids before surgical measures are taken

The sedative action of ETHNINE is particularly useful when it is desired to ensure a restful night's sleep uninterrupted by paroxysms of coughing

ETHNINE

CONTAINING PHOLCODINE

Literature and sample on application

In bottles of 4 and 80 fluid ounces

Research into Pernicious Anæmia

Now that the dust raised by the discovery of folic and vitamin B_{12} is dying down it is possible to e more clearly what is known about the ætiology pernicious anæmia, and how this knowledge can be d in treatment In general outline the picture remarkably similar to what it was before, but the are different Pernicious anæmia is still a deficiency disease CASTLE[1] has put the matter very succinctly

> "the disease would not develop if the patient could effect daily the transfer of a millionth of a gram of vitamin B_{12} the distance of a small portion of a millimetre across the intestinal mucosa and into the blood stream. This he cannot do principally as a result of failure of his stomach to secrete into its lumen some essential but still unknown substance. Yet the patient may each day absorb without much difficulty the products of the digestion of many grams of carbohydrate, fat and protein from foods that in addition may contain consequential amounts of vitamin B_{12} in terms of his trivial need

The original view of the ætiology of pernicious anæmia, as expounded and developed by CASTLE in U.S.A., WILKINSON and UNGLEY in this country their many co-workers, was that for normal poiesis two factors were required an "intrinsic tor secreted by the stomach mucosa—mainly in fundus in man but in the pyloric region in hogs— an "extrinsic" factor associated with protein The intrinsic factor was thermolabile, but its with the extrinsic factor gave rise to a thermo- combination which was thought to be the actual principle, this anti-anæmic factor was stored in the liver, and passed to the bone row Patients with pernicious anæmia lacked factor because of the atrophy of the glands the fundus of the stomach so formation of the anæmic factor ceased The system as we now it still involves an intrinsic factor secreted by the ndal gastric glands and an extrinsic factor present the food It is generally agreed that the extrinsic is vitamin B_{12}, despite the surprising fact that is active when given parenterally without having acted on by the intrinsic factor KLEIN and ILKINSON[2] had originally shown that the product incubation of intrinsic factor from hog gastric sa and extrinsic factor from beef muscle was ive when given parenterally, though neither was ve alone and these and similar experiments had led us to expect extrinsic factor to have an pendent action. In retrospect these findings may e been due to the independent action of vitamin B_{12} present in the beef muscle The fact that vitamin B_{12} produces a prompt, satisfactory, and complete mission when given parenterally in microgramme doses is now established, but doses of the same order given by mouth are ineffective, very large doses are needed for a satisfactory response.[3] But CASTLE and his group[4] soon showed that vitamin B_{12} is effective when given orally in small doses if normal gastric juice is administered at the same time, this finding has been widely confirmed and concentrates from gastric juice and from other sources of intrinsic factor, such as hog stomach mucosa, have given the same effect The present hypothesis is that intrinsic factor and vitamin B_{12} interact to enable the vitamin to pass the intestinal barrier into the blood Research therefore centres on two problems the nature of the intrinsic factor, and the way in which the intrinsic factor acts on vitamin B_{12}.

Work on the intrinsic factor in the last twenty years has established that this is an enzyme separate from pepsin or rennin, and that it is a large molecule probably of protein nature prolinase,[5] aminopolypeptidase,[6] and lysozyme[7] have been suggested, but evidence to the contrary is convincing GLASS and his co-workers considered that the intrinsic factor is, or is associated with the glandular mucoprotein of the stomach, and they claim to have demonstrated the activity of such fractions in pernicious anæmia[8] and in nutritional macrocytic anæmia[9] Similarly LATNER, UNGLEY, and their co-workers[10] concentrated normal gastric juice and subjected the concentrate to electrophoresis they obtained material from two "peaks," and the more active of these—as tested clinically in combination with B_{12}—was either a mucoprotein or a mucopolysaccharide Investigations with microbiological techniques have shown that the level of vitamin B_{12} in the serum of patients with untreated pernicious anæmia is much below normal levels, thus MOLLIN and ROSS[11] found by euglena assay an average normal serum vitamin B_{12} level of 350 µµg per ml whereas patients with pernicious anæmia have levels of less than 40 µµg per ml The idea has been that the vitamin B_{12} in the food is not absorbed, and is presumably excreted, but evidence of this is not easily obtainable by microbiological methods because some vitamin B_{12} is produced in the colon by bacterial action[12] Supporting results have however been obtained by preparing a vitamin B_{12} labelled with the radioactive cobalt isotope Co^{60} HEINLE, WELCH and their co-workers[13] found that when a dose of 0·5 µg of labelled vitamin B_{12} is given to a patient who has not got pernicious anæmia, about 40% of the dose is excreted in the fæces But in 4 patients with untreated pernicious anæmia 72–90% was excreted They further found that by giving normal gastric juice or an ammonium sulphate precipitated fraction of hog stomach mucosa, excretion of a test dose of vitamin B_{12} was reduced to 29% or less. The action of intrinsic factor on vitamin B_{12} has been explained in several ways The original idea that intrinsic and extrinsic factors interacted to produce a hæmopoietic factor different from either seems to be negatived by the discovery that vitamin B_{12} is highly effective alone if given parenterally The next hypothesis was based on the discovery by TERNBERG and EAKIN[14] that normal gastric juice contains a substance that combines with the vitamin B_{12} and makes it unavailable to micro-organisms, they suggested that this "bound vitamin B_{12}" was then absorbed and that intrinsic-factor activity could be measured by estimating the "binding capacity" of the gastric juice or other material. Most work, however, supports the conclusion of PRUSOFF et al[15] that the intrinsic-factor activity of a substance is not correlated with its ability to bind vitamin B_{12}; in fact, using fractions from desiccated defatted hog stomach they found that the fraction most active in potentiating the effect of vitamin B_{12} given by mouth to patients with pernicious anæmia was the one with least vitamin-B_{12} binding capacity. Another possible mechanism might be that intrinsic factor forms a hæmopoietically more active complex with vitamin B_{12}, but CASTLE[1] considers that the evidence is against this hypothesis, too Most probably intrinsic factor specifically facilitates the absorption of vitamin B_{12} by the intestinal mucosa The results with radioactive vitamin B_{12} support this idea CASTLE and his group[16] suggest that the significant relationship is between the intrinsic factor and the intestinal mucosa, intrinsic factor is thought to catalyse some enzyme process in the superficial layer of the epithelium of the small-intestine wall which in turn is directly concerned with the absorption of vitamin B_{12} Since there is no evidence that absorption of other food substances is abnormal, this effect of intrinsic factor must be specific for vitamin B_{12} Dr FOY and Dr KONDI in their latest work on the nutritional megaloblastic anæmia of Africans, published last week,[17] had a group of patients who would respond only to vitamin B_{12} given intramuscularly, and these patients had atrophic gastritis and complete achlorhydria, whereas other patients who had this nutritional anæmia owing to vitamin B_{12} deficiency but had normal gastric secretion responded to vitamin B_{12} given by mouth, or to alteration in their intestinal flora by penicillin so that enough vitamin B_{12} was produced to give a response Thus intrinsic gastric factor seems to be necessary for the absorption of vitamin B_{12} whether taken by mouth or produced in the intestine

The efforts of chemists have turned to producing a concentrated intrinsic factor fraction that is stable and can be applied therapeutically SPIES and his group[18] point out that such fractions, combined with a small dose of vitamin B_{12}, would provide a practical agent for the oral treatment of pernicious anæmia Active fractions from hog stomach have been prepared by PRUSOFF, WELCH, and their associates[15] in which the final protein content was only 0 03% of the original crude source, and such fractions were still not homogeneous by electrophoresis Commercial preparations of active fractions of hog stomach or hog duodenum combined with small amounts of vitamin B_{12} have now been put on the market, the methods of preparation have not been reported, but they are probably similar to those by PRUSOFF et al. GLASS and BOYD[19] have the results with one of these commercial pre in pernicious anæmia good response, with a rise of red blood-cells and hæmoglobin, was o from 60 mg. of intrinsic-factor concentrate with 15 µg. of vitamin B_{12} orally daily. It has not been shown that such mixtures will give effective tenance, and at present treatment with these preparations is very much more expensive than regular parenteral doses of vitamin B_{12} with desiccated stomach and proteolysed liver mouth used to be popular and was certainly effective, but today their comparatively high discourages their use. If these newer pr prove their worth, and their price can be reduced, treatment will again be much used But regular vision is no less necessary than with treatment BREBNER[20] has lately emphasised this his review of a group of patients with anæmia seen at a non-teaching hospital, commonest cause of major relapse was a period inadequate treatment.

The Culture and the Breakdown

IN finding expression the troubled mind makes of the material to hand Any contemporary great or trifling, can be dramatised to make anxiety dream, any current belief harnessed to hysterical manifestation Prof RALPH LINTON, in Thomas William Salmon lectures delivered last m to the New York Academy of Medicine, pointed that in fact the influence of the culture runs the manifestations of mental disorder in every The relation of the individual with his culture reciprocal he is shaped by it and he contributes its shaping As he grows up, his culture infl him in three ways—by what other people do to (especially in the way of child care and training), what they deliberately teach him, and by what he of their behaviour to other people The last is stronger influence than is often supposed, for ability of the child to compare the treatment he getting with that received by others affects valuation of himself, and helps to determine relationship with his parents We are still not sure what period the culture exercises its influence on the developing personality, though it will be during the early years of life Prof Lin notes, however, that recent research suggests infantile experiences—toilet training and patterns—are not such important personality deter minants as was formerly supposed

The influence of the individual on his culture exerted when, as an adult, he is able to accept or new ideas Since all members of a society are to much the same cultural influences, it is not ing that certain personality resemblances run thro particular societies, though of course there is general identity of personality structure all personality can be found in any society (provided it is reasonably large), but the frequency with which given type of personality appears will differ from one society to another The type of personality occurring most often in a particular society is termed basic personality ", and the basic personalities of ifferent societies naturally differ considerably. Except r cultures undergoing rapid change the basic personity will be congruous with the culture, and those who re happily equipped with it will be able to participate the culture with a minimum of frustrations and a aximum of rewards. All societies have neurotics, sychotics, and hysterics recognised by other members f the society as such, but their symptoms differ from ociety to society in ways which strongly suggest that ey have been shaped by cultural influences. Morever societies differ in the way they deal with people lowing these disorders and some make social use f particular forms of psychic abnormality. The bnormalities themselves, however, seem to crop up all societies, and as LINTON puts it "individuals ith the constitutional defects responsible for such bnormalities would be abnormal in any society." robably these defects have a physiological basis. here the personality of an individual departs idely from the basic personality of his society, tests istory taking, and analytic studies indicate that his rly experience has often been atypical for his society.

It would be interesting, of course, to know something ore about psychoses in non-European societies, but e data are scanty. The most useful reports come om Africa, where all types of insanity found in uropeans seem to be present, though the frequencies iffer. Thus depressive reactions are exceedingly rare Africans—and so indeed, is self-reproach. The rican blames his environment rather than himself, d hence his psychotic response is more often paraid than depressive. It is noteworthy that, among lusional psychotics, literates who have had a uropean education develop symptoms essentially uropean in type whereas non-literates show the rican type of response. From this it has been argued at Europeanisation, and the resultant cultural esses is *not* a significant causal factor in psychosis. lf reproach and depressive states are rare likewise Brazilian Negroes. Among these physical catatonia ounting to waxy flexibility has been seen in patients owing only superficial social withdrawal. Satisctory cultural explanations of these differences NTON says have not yet been offered. Membership a tribe, all closely related is a great support, and y check a patient's impulse towards withdrawal ain, perhaps the violent emotional expression which se cultures permit makes self-reproach unnecessary et, though primitive peoples respect psychotics, arding them with fear and awe, there is no society, ofessor LINTON finds, where the genuine psychotic cupies a favoured social position. To exploit the vantages of abnormal behaviour one must know ry well what one is about and the inability to do is is the real test of psychosis. Medicine men d prophets who make a good thing out of their centricities do not qualify as insane.

euroses seem to be as widely distributed as psytics, though we have no clue to their relative quencies among primitive peoples. However their versality is an argument against FREUD's theory at they originate in sexual repression, for they appear in societies where expression of the sexual impulse is largely unlimited. It is more probable LINTON thinks that they result from the consistent frustration of any primary drive. In the Marquesas for instance, neurotic expressions centre round food rather than sex. In any case there is probably an underlying constitutional factor, for in all societies many people endure experiences which make others neurotic without becoming neurotic themselves.

Now evidence shows that certain types of hysteria have geographical distributions and that these often cut across racial lines. *Amok* is a form of aggressive suicide practised by males: they attack everyone they meet until they are finally killed. *latah* is a condition of complete submission, in which the patient, when startled, imitates the speech and actions of the first person he (or she) sees. *Amok* is limited to South-east Asia, but *latah* is found in Mongolia, North Africa, and the Near East, and is also a component of Arctic hysteria. Supposed spirit possession is found throughout most of the Old World, but not in Moslem countries where possession by spirits other than demons is thought to be impossible. Among American Indians *amok*, *latah*, and spirit possession are almost unknown, though conversion hysterias are common. In Europe and America the pattern of hysterical symptoms has changed in the last few generations. Spirit possession, common in the 17th century, has almost disappeared, and so has *grande hystérie*. So, too has fainting, the hallmark of the real lady; but social distinctions in hysteria are still with us: during the late war conversion hysterias were almost confined to other ranks; officers had nervous breakdowns. LINTON concludes that though a predisposition towards hysteria may be of physiological origin, its manifestations are shaped by the culture to an even higher degree than are those of neurosis and psychosis. The hysterias of course bring advantages: they are designed not only to elicit favourable response from the audience but also to inconvenience and annoy the hysteric's associates, and must be regarded either as an escape mechanism or a response to ego deprivation. It is worth bearing in mind how intolerable must be the situation, how deprived the ego, to drive the patient to such lengths.

Annotations

CHRISTMAS BERRIES

How poisonous are mistletoe berries? No doubt this question is asked in several homes and hospitals at this time of year. In one casualty department last December, a five-year-old arrived with some of the berries inside him. Hasty inquiries were made while gastric lavage was started, only to be thankfully abandoned when the pharmacist gave assurance that mistletoe was a medicinal substance. In fact mistletoe has an illustrious pharmacological history. In an 18th-century treatise it was acclaimed as "a most wonderful specifick remedy for the cure of convulsive distempers." As late as 1908 it could be described (in New York) as "a panacea in therapeutics," and it vanished from the *B.P.C.* only in the great pruning of 1949. By then it had fallen on evil days, lingering only as a vasodilator in hypertension and as a sedative—e.g., in hysteria and chorea. All the same it seems that mistletoe *can* be dangerous, but only if taken in large amounts by a small child. One death is on record; long ago a baby of 15 months was left in the care of his sister aged 6: when he was found nearly comatose, the little girl confessed that she had fed him with the berries because she found them too bitter to eat herself. After an emetic the child vomited a great quantity of berries but died soon afterwards. On

…nother occasion, a boy of 14 was found unconscious in the street, an hour after eating eight mistletoe berries It is said that the doctor suspected alcoholic intoxication, and at that season he may have had cause

Holly berries may also be sampled, but this need cause even less anxiety, for their effects are mainly purgative The only report of holly poisoning we know of appeared in our columns [1] in 1870, when a boy aged 3 ate a number of the berries He soon had bilious vomiting and copious diarrhœa, berries being seen in the motions. After welve hours he lost consciousness, but had fully ecovered next day The winter cherry or Jerusalem herry, commonly found as a decorative pot plant, another berry which may prove too attractive at iristmas-time Two species are *Solanum capsicastrum* d *S pseudocapsicum* *S capsicastrum* is the usual one l is believed to be harmless, but children have died r eating *S pseudocapsicum*, and even three or four ies can produce symptoms A 2 year-old boy died itly in Italy after eating these berries, which rently he found growing wild.[2] Vomiting was very e and was followed by convulsions and coma A winter cherry is thus the most dangerous of the three There is no specific antidote for any of these berries If any significant quantity has been taken, emesis or gastric lavage will give peace of mind. Thereafter, the treatment is symptomatic.

"SCALENE NODE" BIOPSY

It is occasionally very difficult to get histological evidence of intrathoracic disease Abnormal tissue may be sought by bronchoscopy, thoracoscopy, and thoracotomy, or by examination of sputum and pleural fluid. The search can be extended further by liver biopsy, sternal puncture, or removal of enlarged superficial ymph nodes But commonly no nodes are palpable, and the removal of the deeper, impalpable ones may seem worth while Daniels,[3] for instance, dissected out the nodes lying on the scalenus-anterior muscle in patients with sarcoidosis, bronchial carcinoma, and silicosis and found abnormal tissue in them

Shefts et al [4] have made this investigation in a very much larger series They report the results of 205 dissections in 187 patients with intrathoracic disease in whom histological evidence had not been obtained by other methods There were abnormal findings in 67 (35%) These "scalene nodes" are said to be connected with the mediastinal nodes, and it might be assumed that the pathological process in one of these two groups is always the same as that in the other But this is ıot necessarily so It is not known how commonly aseous tuberculous changes affect the deep cervical odes of patients who have no radiographic evidence of trathoracic tuberculosis, the nodes receive lymph m many sources and the tuberculous infection may ve travelled down from the throat and not up from the ıung Moreover, microscopic tuberculous changes in the mediastinal nodes are so commonly present without the patient having "tuberculosis" that, even if the infection of the cervical nodes has been by way of the mediastinum, there must still be doubt whether the intrathoracic abnormality being investigated is tuberculous Similar caution might be wise in interpreting the nodal changes associated with sarcoidosis, for noncaseating tuberculous lesions are sometimes found in the mediastinal nodes of patients with pulmonary tuberculosis

Shefts et al suggest that this investigation may be useful not only in detecting bronchial carcinoma when other methods of investigation have failed but also in detecting those proved cases of carcinoma in which the disease is too far advanced for surgical If the sole aim of resecting bronchial carcin to eradicate all cancer tissue, this prelimina might save some useless operations But remo affected lobe or lung in patients with small metastases may, even if it does not postpone make what is left of life happier. Additional from the pathologist, although refining the diagnos not help either in treating the patient or in the course of his illness. Excision of deep cervic nodes may be safe and cause the patient only discomfort, but this investigation should perhaps reserved chiefly for obscure intrathoracic where histological evidence is necessary for treatment

PREPARATION FOR TONSILLECTOMY

" . the emotional equipment required for adequately with a hospital experience is no differe that needed in dealing with all the other problems

TRUE enough, but the research team at the College, New York, who make this observation aware that life, taking us by surprise, can rattle our emotional equipment considerably may respond to such an experience with neurosis or psychosis, but the child usually responds with beha disorders

It is no new finding that admission to hospital tonsillectomy can be a harmful experience for and the research team, under the direction of Dr. Otto Faust, tried to find out whether careful preparation handling reduces the emotional injury. For one or another their original plan for a controlled had to be given up, but in the collected papers form the basis of their final report,[1] to which Mac Keith refers in a letter this week, they set methods they used to reassure children and to r them to their former pursuits free from symptoms. Briefly, their method was to choose laryngologists and anæsthetists with experience of sympathy for, children, they ensured that the atmosphere was kindly, they allowed one paren remain in hospital with the child throughout his and they sent a social worker to visit the child in home before operation, to tell him what to expect

There were 140 children aged 3–8 in the and the key people in preparing them to face o confidently proved to be the social worker and anæsthetist The social worker visited the home less than a week before the child was due to be made friends with him and his mother, and noted setting in the family She described to the child size of the hospital, what he would see as he entered doors, the ride in the lift, the way the doctors nurses would be dressed (which some children frightening), the ward, the other children, and the of bed he would sleep in (for some, having from a cot to a bed, are affronted by the cots in a ward) She also advised him to take a favourite toy him Thus interview fortified him for his arrival hospital, especially since his mother usually went him

On the evening before his operation the a woman—visited him and took pains to gain his dence She found out whether he had had an before, and judged for herself how he felt about it; also learned, from conversation with the mother, he had been prepared for the operation at home—w in fact, the suggestions he had received had been or accidental positive or negative She explained him carefully that he would go to s except for a sore throat afterwa and she let

[1] Reducing Emotional Trauma in Hospitalized Children. the departments of pediatrics and anesthesiology. Medical College Albany, New York. 1952 Pr

the mask, telling him that he could hold it over his himself, and that breathing the medicine on it would him fall asleep She described simply the queer dizzy feeling he might have while falling asleep, and told him about the theatre and the sort of clothes *the doctors would be dressed up in*

day she came herself to take him to the operating e, and faithfully kept her promise to let him hold mask. She seldom found that a child wished to lift mask or throw it off and if a child became nervous a reassurance, and the placing of her own hand over not as a restraint but to give confidence—usually to calm him Premedication was slight, or not at all She found that with this method the tion time was shortened, the stage of excitement was severe (usually lasting only a second or two) and child needed less of the anæsthetic agent She also d that such an experience far from diminishing a d's courage, usually reinforced it Having taken the it gamely he rose in his own esteem

Some other general principles were put into action with e children It was found that rectal temperature ng was alarming and so of course were enemata *were given up, and the temperature after the* tion was taken only at night in the groin or the a. Since the children dreaded injections, these too o avoided, except for an injection of atropine just re operation and a needle prick for hæmoglobin imation

The social worker visited the child at his home ten days the operation and again two or three months later, see whether he was showing any evidence of increased y She estimated that, of the 140, 13 showed favourable behaviour changes but some of these, use they had belonged to a group originally intended controls, had not been so carefully prepared for the etic as the rest of the experimental group The ren treated with consideration for emotional factors less evidence of trauma than those who were not than half of the 140 showed behaviour that was r unchanged or improved, and about a third showed mixed response being improved in some traits and rbed in others in most of these cases, however the r thought that on the whole the child was better d. The younger children in the series showed more milder adverse behaviour traits than their seniors.

BRONCHOGRAPHY IN PULMONARY TUBERCULOSIS

IT is a commonplace that pyogenic inflammation in lung may be followed by bronchiectasis, but the uency with which this takes place in tuberculosis often underestimated. Apart from the dilatation an episode of bronchial occlusion during the ry infection, bronchiectasis is often produced the resolution and repair of the long-drawn out onia of pulmonary tuberculosis. There is usually point in attempting to distinguish between the shadows the active pneumonia and those of the fibrous repair may follow, but it is a fact that bronchiectatic areas lung may produce an appearance deceptively similar active tuberculosis, particularly in upper lobes which ve been subjected to collapse therapy and that dowing thought to represent infiltration may largely from bronchiectasis.

The frequency of these events cannot be appreciated less bronchography is widely practised on the tuberculous and there are good reasons for not doing this The most valid practical objections are the difficulty the retained Lipiodol may cause in future interpretation of the chest films, the danger that its presence may mask a spread of the disease, and the possibility—even though remote—of the investigation provoking a flare up of the illness On the other hand, should the surgeon wish to know the state of the bronchi before operation it may be necessary to undertake bronchography in spite of these risks, and a new medium for bronchography has recently been introduced which is particularly suitable *for these cases Dionosil is a suspension of diodone in* oil or water and it is absorbed from the lung within a few days. It thus overcomes one of the main disadvantages of lipiodol, and there have been favourable reports on its use[1,2] At the moment, however these media have certain disadvantages not encountered with lipiodol. They are more irritating to the bronchi and anæsthesia has to be more cautious and complete, and therefore more time-consuming Febrile reactions often follow within twenty four hours accompanied sometimes by bronchitis pneumonia or collapse of the lung these complications may not be serious, but they are certainly unwelcome and may tend to restrict the use of these media to patients in hospital As they are less viscous than lipiodol the new media can be introduced through a smaller needle or catheter and yet they do not run as readily into the alveoli They are not quite so radio-opaque as lipiodol but the contrast they provide is usually adequate. They are still being developed, and if they can be made less irritating and more opaque, they may prove a valuable aid to the planning of treatment and the evaluation of its results.

SCIENCE TEACHING AT SCHOOLS

THE shortage of teachers of mathematics and science in the schools which has caused concern since the end of the war is likely to get worse in the next few years when the post war bulge in the birth rate will affect the secondary-school population.[3] A report by the National Advisory Council on the Training and Supply of Teachers[4] describes the findings of a subcommittee which worked under the chairmanship of Sir Charles Morris It ends by saying:

> We consider that the shortage of graduate teachers of mathematics and science constitutes a national problem we feel bound to emphasise our conviction that unless enough men and women with suitable abilities and *qualifications come forward to teach in schools there must* be serious long term effects both on the general quality of education of the nation and on the future supply of scientists and technologists.[4]

The report gives an estimate of the average annual requirements of graduate teachers of mathematics and science in grant-aided schools in the period 1950–60 This is 580 a year for the five years 1950–55 and 1020 a year for 1955–60 These figures are on the low side for the subcommittee takes as its standard the staffing conditions prevailing in 1950 though like other authorities, it does not regard these conditions as satisfactory The deficiency in teachers is not only quantitative but also to some extent qualitative: in 1953 only 18 men with first-class honours in mathematics or science left university departments of education compared with 48 in 1938 and the first-class and second-class honours graduates together formed only 30% of the total in 1953 compared with 60% in 1938

The council *suggests increasing the attractiveness of* school teaching by improving its prospects and working conditions—for instance, by providing laboratory assistants. At present the schools are at a disadvantage in competing with the universities and industry for the most promising graduates. Unless however the total number of graduates can be increased this policy would involve robbing Peter to pay Paul and Peter himself

is not well placed. The fact is that there is an all-round shortage of good science graduates, and some university teachers doubt whether suitable students can be recruited in larger numbers than at present For this there seems o be no quick and easy solution

Where a boy or girl has early made the decision to come a doctor, inadequate teaching of science at school is unlikely to deter him or her from trying somehow to pass the first M.B examination before going to a university or medical school. But lack of suitable teachers at school may prove a serious handicap to the boy who decides late. At present, unfortunately, those who have passed the first M.B examination have a better chance of gaining admission to a university or medical school than those who have not; and if this policy is to be maintained the universities will at least have to make sure that failure in this examination due o inept teaching does not unfairly debar a candidate om admission The alternative would be to restore to universities the responsibility for teaching the first M.B subjects to all students This would have the effect of prolonging more general education at school, and would put all candidates on a more equal footing, but it would also extend the very lengthy professional training, and transfer to the universities some of the staffing difficulties which now beset the schools University and school authorities will do well to examine this problem together before the increasing dearth of teachers makes action inevitable

HEPARIN AND ATHEROMA

THE use of heparin in the treatment of coronary disease and the development of synthetic analogues, such as dextran sulphate,[1] raise an interesting question The rationale of using heparin to combat coronary thrombosis was that it prevents clotting Biochemists, on the other hand, have been quick to suggest another type of action on atherosclerosis, due to the very far reaching effects of heparin injection on the circulating lipoids—an action which is not shared by dicoumarol and phenylindanedione

In 1943 Hahn [2] observed that the turbidity of alimentary lipæmia in the dog was almost immediately cleared y an injection of heparin, but adding heparin solution drawn blood had no effect on the turbidity Seven years later Anderson [3] found that the plasma of a heparin-injected animal would clear lipæmic plasma in vitro The mechanism of this action is complicated It has been shown to be due to the coupling of a plasma constituent with heparin by an enzyme present (in the rat) chiefly in heart and lung tissue The resulting "clearing factor," in the presence of yet another plasma constituent, can reduce the turbidity of lipæmia [4]

The detergent-like action of heparin clearing factor (H.C F) might have remained a curiosity if it had not also been observed [5] that heparin injection brings about redistribution of the lipoprotein fractions determinable with the ultracentrifuge, and that in this process there is a pronounced reduction of that group of low density lipoproteins which the Donner Laboratory workers have regarded as closely and perhaps causally, related to atherosclerosis [6] The statistical evidence for this view has been severely treated [7], but the fact remains that a concentrate of this fraction, prepared by cholesterol eeding in the highly atheroma susceptible rabbit, can aduce cholesterol atheroma when injected into other animals,[8] and that administration of heparin substantially protects rabbits against cholesterol feeding.

Speculation has followed these findings. It possible that differences in the activity of the system at some point in the chain might account specific differences in susceptibility to dietary (since the rat is both highly resistant and a good pr of H C F, while the rabbit is highly susceptible and poor producer [4]) and even for individual and age ences in human susceptibility.[10 11] These are interesting but premature The comparative of the response to heparin in different laboratory is now being elucidated. It shows signs of inconveniently complex as such relationships usually

Injection of heparin has no effect on the turbidity rabbit plasma,[4] but in some strains at least it lipoprotein distribution [5] and protects against It has also been found that, despite the failure of he to clear rabbit plasma, it brings about a striking selective increase in the electrophoretic mobility of lipoprotein fractions, especially the β component is the fraction affected chiefly by cholesterol fe This enhancement of mobility disappears be critical blood-lipoid value—either because an constituent also disappears below that value or more probably, as a result of a change in the concentrations of different lipoids. Rabbit plasma heparin injection both clears lipæmic dog or plasma and accelerates its β lipoprotein.[12] The scence of lipæmic rabbit plasma clearly differs in important respect from that of dog, or normal lipæmia, since it is not cleared even when mixed nine times its volume of active H C F-containing pig plasma Rat plasma is sometimes active as a clearing agent [4], but this is occa- observed even in rabbits [14]. There are signs that plasma can occasionally couple heparin added to vitro, and therefore presumably may contain "tissue factor," the enzyme responsible for the process [4 14 15] Block et al [16] found that clearing more slowly after heparin injection in ather than in normal people

From this confusion the only clear inference be that if heparin does protect against atheroma mechanism by which it does so is more closely the ultracentrifugal and electrophoretic changes which produces than to the dissolving of chylomicrons leads to optical clearing Physicians will probably to wait until the biochemists have finished. But apart from the great importance of differences in animal and human susceptibility to from a high cholesterol diet, to which the study heparin may contribute much, the use of heparin treating or preventing coronary disease may, on basis of such work, prove to be twofold. The and even more the lipoprotein-accelerating, actions heparin in the normal person occur with ver lower doses (10–20 units per kg body-weight) than anticoagulant action It would be interesting to kn supposing that heparin really reduces the incidence coronary attacks, how far low doses of this order (they would need to be very frequent), and how action of heparin compares with that of which have no such physicochemical effects on metabolism

THE NURSING OF ADOLESCENTS IN ADULT WARDS

A. C. STUART CLARK
M.A. Camb

OR TUTOR, HOSPITAL ADMINISTRATIVE STAFF COLLEGE,
KING EDWARD'S HOSPITAL FUND FOR LONDON

o some extent all patients in a ward are living in ormal circumstances. But adolescent patients have cope with the double abnormality of illness and lescence From time to time parents and teachers e expressed doubt as to the wisdom of putting lescents in the same hospital wards as adults

n adolescence the imaginative faculty is heightened l to some extent distorted, and introspection tends play a large part in conscious thought. Is there not, refore a risk that adolescents in a ward, who inevitably m a small proportion of its population will be essively spoilt by their elders, or will feel lonely earing in mind the fact that loneliness is not neces lly overcome by association with people but with ple of the same age or outlook?

nother ground for disquiet is the conversation and eriences to which the adolescent patient may be osed Particularly in surgical wards sights and unds, which are inevitable, cannot always be kept m the young Fear of the unknown and of what sees but has not experienced is always powerful, re especially in adolescence It is no part of a pital's duty nor that of the hard pressed nurses to sor conversation between patients On the other nd, detailed discussion of symptoms and forms of atment often make terrifying hearing to the young part entirely from the possibly unedifying advice en by some adults on matters of sex This is not to ply that the conversation of adolescents among mselves cannot and does not reach at times a pretty r level but it is far easier to argue against one's temporaries—who can be regarded as being as orant as oneself—than to reject the dicta of the ult who may claim to have experience and whose ars, however unjustifiably appear to lend authority his remarks.

To discover whether these doubts are in fact well unded I sought the opinion of matrons and sisters on ese points. It has not always been possible to extract m the replies to our questionnaire information which n be exactly classified, as the use to which wards are t changes from time to time and the figures quoted e accurate generalisations rather than precise statistics e views expressed were sometimes an agreed view t forward by the matron on behalf of her ward sisters d sometimes the views of the ward sisters themselves.

NUMBER OF ADOLESCENT PATIENTS

The inquiry covered 3954 beds contained in 105 wards. 0 of the beds were occupied by adolescents between e ages of 12 and 17 (9·08%) I have omitted figures r long stay patients and for wards likely to consist in e main of adolescents—for instance ear nose, and roat. The information provided therefore is based on neral medical and surgical wards. The beds were vided as follows

Ward	No. of beds in ward	Adolescents No.	Adolescents %
emale medical	881	60	6·8
surgical	1200	107	8·9
ale medical	805	97	12·05
surgical	1068	95	8·9

he hospitals from which these figures were obtained are pread over the whole of England and Wales and there oes not appear to be any variation according to district.

Of the 160 replies received 137 considered that adolescents and adults should be nursed separately, 13 preferred to nurse both together Where the replies took the form of a single letter expressing the view of a number of ward sisters it has been treated as a single reply and in every such case preference was expressed for separate nursing

NURSING OPINION

The following general points emerged from the inquiry

All agreed that the adolescent girl ought never to be nursed in a gynæcological ward, and it was generally felt that the risk of fear and of less pleasant forms of conversation was greater in female wards than in male because women were less careful and considerate of the younger members of the ward than men.

Many replies expressed the view that the adolescent (particularly in the male ward) became spoilt if his stay was more than a few days.

Difficulty is experienced in some wards where adolescents during their convalescence irritated the older patients by noise, playing games and so on

A strong preference was expressed by a large majority for the provision of an adolescent annexe or ward and it was clear that most ward sisters took considerable care to segregate the younger patients, either by curtains or by the use of verandas or by keeping adolescent patients in beds next each other

In hospitals for long-stay patients such as sanatoria and orthopædic hospitals, the situation is different for educational and other provision is made for young patients which is not possible in a general hospital But the replies to my questions make it clear that the percentage of adolescents in general hospital wards is substantial, and this fact coupled with the overwhelming weight of opinion in favour of segregation expressed by those most directly connected with the life of the ward, suggests that a problem exists of sufficient size to justify fuller and more detailed consideration than has been given it hitherto

MEDICAL RESEARCH IN THE COLONIES

PUBLIC attention is drawn to the British Colonies chiefly by things which have gone wrong in most of these territories affairs are going rightly and therefore remain unnoticed Development of a more prosperous and advanced way of life is being assisted by substantial payments from the British taxpayer through the Colonial Development and Welfare funds. Part of these funds is devoted to medical research, and the ways in which this is applied are shown in the latest report of the Colonial Medical Research Committee.[1]

MALARIA

The disease which has received most attention is malaria which has been studied in Borneo Malaya, East Africa West Africa Trinidad and the West Indies —in fact all round the world except in the Pacific islands which fortunately are free from it. Some of the work is directed primarily against the mosquitoes which transmit the malaria parasites, this includes careful studies of the habits and breeding places of the various species of anopheles, of methods of making the breeding places unsuitable by partial clearing (as with *A leucosphyrus* in Borneo) and of the practicability of destroying the adults with gammabenzene hexachloride ('Gammexane') and D D T (as in Trinidad Malaya and elsewhere) An investigation carried out at Ilaro in Nigeria during the last five years shows that it is quite feasible by residual spraying of gammexane to reduce malaria to negligible proportions with considerable falls in the crude and infant death r
but the average cost of 4s 9d. per head per year
low by Western standards, is too high f

---

[1] Colonial Research, 1952–53. Colonial mittee Eighth Annual Report. C Office. Pp 268 1s 6d

to be generally applicable in the poor countries of Africa

Other work is directed chiefly towards the malaria parasites as they occur in man. Therapeutic trials of new antimalarial drugs have been carried out in Nigeria and Malaya, the chief tests have been on pyrimethamine ('Daraprim') and the 4-aminoquinolines such as chloroquine and amodiaquin In endemic areas (e g, tropical Africa) the chief sufferers are always the children, who have repeated attacks and many of whom die either from malaria or from other causes It has always been debated whether those who survive and reach adult life continue to be harmed by persistent low-grade infection or whether they have become so completely immune that it is not worth while, or even desirable, to protect them from further infection by controlling or eradicating the parasites Decisive evidence may be obtained from a scheme for an isolated district of East Africa where malaria will be wiped out by insecticides and chemotherapy, and the effect on the health of the indigenous population will be carefully studied.

VIRUS DISEASES

Considerable funds and effort have been given to virus research, especially to the control of *yellow fever* Two large institutes, at Entebbe in Uganda and near Lagos in Nigeria, are devoted to this purpose Thanks to the efficient vaccine which was developed during the 1930s by the Rockefeller Foundation it is now possible to protect individuals and whole communities, but there are still many interesting problems concerning the maintenance and dissemination of the virus by mosquitoes and monkeys in forest areas, from which it may later spread to man

Studies on *poliomyelitis* have been made in Uganda, the infection is probably widespread among Africans, but it seldom causes ill effects in them

Scrub typhus and similar infections have been studied in Malaya in collaboration with a U S army medical research unit, owing to interruptions caused by banditry, part of the work was done in Borneo

Relapsing fever and its dissemination by ticks has been studied in East Africa This infection is so common in many areas that the Africans in those parts become immune from repeated minor attacks, but newcomers to these districts—e g, immigrant labourers—have repeated severe bouts of fever which are always deleterious and sometimes fatal In the first world war it caused many deaths, and it is still a menace In this case, as in other insect borne diseases such as malaria and sleeping sickness, much help in tracing the particular species responsible for transmission has been received from a new organisation for identifying the blood found in the insects' stomachs This is dried on filter-paper and sent to a central laboratory at the Lister Institute There a great collection of sera from animals of all kinds has been accumulated during the last few years, and appropriate antisera have been prepared By special precipitin and other tests it has been possible during the past year to identify the source of over 5000 blood samples sent from Trinidad, Kenya, Tanganyika, Nigeria, and other parts of the world

FILARIAL DISEASES

Loiasis, the filarial infection which is the cause of much annoyance to Europeans and Africans in the forest areas of West Africa, has been studied at Kumba in British Cameroons The breeding places of the mangrove fly, chrysops, which transmits the infection have now been identified, and valuable information is being obtained about the habits of this pest, which will [illegible] it to be controlled and even eradicated [illegible] spread filarial infection due to [illegible] which causes *elephantiasis* of [illegible] has also been studied in Tanganyika, [illegible] Malaya Diethylcarbamazine administered by mouth

to all the members of an infected community probably reduce the infection to negligible at which level it might be unable to and so might become extinct Unfortunately often causes nausea and other minor toxic effects make the treatment unpopular and community The cost of treatment would also deterrent to its widespread application

LEPROSY

Leprosy is widespread in Africa and in Malaya research-workers to study it are difficult to because of the slowness in obtaining results intractable chronic condition and because of the tion which such work often entails. Most investigations have been carried out, Uzuakoli in Nigeria, where it has been shown oral administration of diaminodiphenylsulphone effective, simple, safe, and widely practicable treatment Thiosemicarbazones, such as (T.B 1), may be useful in special cases, esp patients who have become allergic to sulphones, they require close medical supervision during the weeks Isoniazid, which produces such dramatic in tuberculosis, has proved of little value in

OTHER DISORDERS

Besides the infections with which unfo tropics teem, other causes of ill health have been studied. The condition among African children is often called *kwashiorkor*, and which is by œdema, dermatitis, anæmia, and s hair, can be successfully treated with a high diet, but the provision of such a diet is often since in many parts of Africa milk is not o any large quantity Work at Kamapala in U has shown that even young children will diets of soya bean and other plant protein W this and other nutritional problems is being und at Fajara in Gambia, where a research station has established by the Medical Research Council

Attention has also been given to the problems of hot climates, especially by the Hot C Physiology Research Unit at Oshodi in Nigeria carefully designed investigation has exploded the fallacy that frequent drinking is bad, on account of general physiology and of water economy it is be to take frequent small drinks than a few large c the same total volume

Medicine and the Law

Forceps Left in Abdomen

A 64-YEAR-OLD woman who underwent an operation in a Birmingham hospital last month days later, and at an inquest[1] on Dec 10 her dea said to have been accelerated by a pair of artery that were left in the abdomen at the operatio gynæcologist said in evidence that he was not tol a pair of forceps was missing after the operation 36 hours the patient's condition was satisfactory deteriorated later, though her symptoms were unusual after such an operation The theatre sister that the swabs were checked and found correct, but was told that a pair of forceps was missing She that they were still attached to the cyst that had removed and she had intended to check this but to do so The coroner commended the hospital ties and the theatre sister for their frankness coroner's officer who had dealt with the matter verdict of accidental death was recorded added a rider recommending an person should be responsible for a c on all and swabs at all future operations."

Before Our Time

LIFE OF THE SHAWL

DOUGLAS HUBBLE
M.D Lond M.R C P
DERBYSHIRE ROYAL INFIRMARY

is medical mythology of the 16th and e seat of melancholy lay in the liver, and the spleen Depression was con hypochondria, and the frequency with disturbance accompanied melancholy ttle should be bold enough to question en taken as a sufficient proof of a ypothesis.

tury hypochondria was as fashionable ty today and in 1790 Erasmus Darwin, Charles, wrote: the hypochondriac indigestion and consequent flatulency ant of pleasurable sensation' These o be accepted until the 19th century Charles Darwin suffered from hypo had its popularity waned, but the on a more sinister meaning In 1873 is *Principles and Practice of Medicine,* the name hypochondriasis has very as indicating the character of and seat while the *Oxford English Dictionary* tually defined it 'as chiefly charac tient's unfounded belief that he is some serious bodily disease This d can now be elaborated by observing preoccupation with his bodily function some environmental overcare which ates his own apprehension, that it is notion that the hazards of ill health by the exercise of precaution and that perpetuated by some immaturity in the patient

ming testimony in Charles Darwin's s children's reminiscences, and in the n of family letters that his illness was ical Much of the evidence was collected in my article in this journal in 1943 where it was shown that his illness provided the exact conditions which were essential to his achievement his disordered and sleepless nights allowed his laborious mind to brood in solitude over a generalisation, while two hours *observing and recording in the morning* would expose the night's hypothesis to realistic examination and complete the day's work It was assumed too that the immaturity of Darwin's personality provided sufficient explanation of his hypochondriasis.

There was then no published evidence as to the existence of any environmental overcare which equalled and enhanced his own apprehension. This deficiency has now been made good by Mrs. Raverat's delightful book *Period Piece* This book completes a family record which spans the 19th century, and without it the tale was but half told The modern descendants of these great Victorians may protest their distaste for such chronicles (Mrs Raverat tells of an anti Darwin league formed by those who have 'inadvertently married Darwins'; Emma Darwin might suitably have been chosen as the first president, for she wrote in 1879 irritated by a long discussion of the 200 year Darwin pedigree, I don't know how it is, I should care *a little* if it related to Wedgwoods) Yet they are social documents of great value The fortune built by Robert Darwin in his Shrewsbury practice was sufficient to maintain his children in comfort his grandchildren too shared the economic security then enjoyed by the English upper middle classes. But the grandchildren were not typical of their class or time They had little enthusiasm, individuals excepted for art or for religion and in their preoccupation with natural phenomena they were apostles of science and disciples of the spirit of inquiry, true forerunners of the 20th century

The first family tree (see below) shows Charles Darwin's family and its ancestry through three generations. Ten children were born to Emma and Charles Darwin, and of these, seven reached adult life. Of the five sons George, Francis, and Horace had careers of great distinction and were knighted for their varied scientific achievements. A fourth son Leonard Darwin, is still well *remembered as the president of the Eugenics Society* and of the Royal Geographical Society Such facts as these

seemed to justify the conclusion that in the happy family life at Down House the Darwin children grew to serene and undisturbed fulfilment It appeared that even the continued illness of Charles brought his children nothing but gain: it gave them more of his delightful company, it ensured regular living and an ordered existence, and it required of each of them those small daily sacrifices which are the necessary accompaniment of a happy communal life. The new facts supplied by Mrs. Raverat not only allow a further assessment of the factors contributing to Darwin's hypochondria, but demand consideration of the astonishing ill health displayed by his children

Charles's Health

The only hypochondriacal illness suffered by Charles before his marriage was at Plymouth in 1831, when for two months he waited in wretchedness for the *Beagle* to set sail.

"These two months at Plymouth were the most miserable which I have ever spent, though I exerted myself in various ways. I was out of spirits at the thought of leaving all my family and friends for so long a time, and the weather seemed to me inexpressibly gloomy I was also troubled with palpitations about the heart, and like many a young ignorant man, especially one with a smattering of medical knowledge, was convinced that I had heart-disease I did not consult any doctor as I fully expected to hear the verdict that I was not fit for the voyage, and I was resolved to go at all hazards"

Charles was a good observer and in these few sentences he recognised the antecedent emotion, the disturbing physical symptom, and the peculiar suggestibility of the one-time medical student and the doctor's son He shows his courage, too, which he was to prove many times in the [illegible] dangerous years which followed

He remained well until after his marriage in 1839 He became ill in the following year during his wife's first pregnancy and was incapable of sustained work throughout the succeeding two years From the published correspondence it can be concluded that, thus early in their married lives, the life long rôles of husband and wife were already determined. He was the invalid incapable of social activity, and she was the devoted nurse who in Maria Edgeworth's words "was debarred from all London gaieties and all gaiety but that of her own mind by close attendance on a sick husband" London then was without attraction for both, and, since Robert, his father, had little hope that Charles would regain his strength for years to come, they moved in 1842 to their country refuge at Downe Nursing was Emma Darwin's métier "She was a perfect nurse in illness Her self-command never gave way, and she was like a rock to lean on, always devoted and unwearied in devising expedients to give relief, and neat handed and clever in carrying them out" Mrs Raverat is both more explicit and more percipient 'I have sometimes thought that she must have been rather too sorry for her family when they were unwell A little neglect or astringency might have done some of them a world of good" In the Wedgwood enjoyment of sickness lay the emollient influence which fixed irreversibly Charles Darwin's hypochondriacal habit The perfect nurse had married the perfect patient

It is not surprising that many of his friends, accepting his appearance of robust health as better evidence than his recital of agonising nights and valetudinarian days, diagnosed his disorder as hypochondriasis Charles mildly protested in a letter to Dr Joseph Hooker (June 13, [illegible]) "Everyone tells me that I look quite blooming [illegible]tiful, and most think I am shamming, but you [illegible] an one of these" Such mild acceptance of [illegible] without an outward aggressive reaction [illegible] Charles Darwin He ha[illegible] [illegible]thoritarian
